Lecture – 36

We are moving into the next important result of finding variance of sum of random variables.

(Refer Slide Time: 00:06)

Next definition that is let X_1, X_2, \dots, X_n be a n random variables having finite variances; then one can define variance of sum of random variables from i is equal to 1 to n let X_1, X_2, \dots, X_n and be a n random variables, having a finite variances; that means, first and second order moment exist and it is finite.

Then we are defining the sum of random variable that is going to be individual variance plus the double summation over covariance between any 2 random variables provided i and j is not equal. That is a variance of sum of random variable is the variance of individual random variable with summation plus covariance of any 2 distinct random variable that is going to be the variance of sum of random variable.

This can be rewritten, this can be rewritten that is summation of i is equal to 1 to n variance of each random variable.

(Refer Slide Time: 02:25)

The image shows a screenshot of a Windows Journal window titled "classification_rv_function_of_rv - Windows Journal". The window contains handwritten text and mathematical formulas in red ink on a lined background. The text reads: "Definition Let X_1, \dots, X_n be a n rvs having finite variances. Then". Below this, the variance of the sum of random variables is derived:
$$\text{Var}\left(\sum_{i=1}^n X_i\right) = \sum_{i=1}^n \text{Var}(X_i) + \sum_{i \neq j} \text{Cov}(X_i, X_j)$$
$$= \sum_{i=1}^n \text{Var}(X_i) + 2 \sum_{i < j} \text{Cov}(X_i, X_j)$$
 Then, it says "Suppose X_i 's are independent rvs." and concludes with:
$$\text{Var}\left(\sum_{i=1}^n X_i\right) = \sum_{i=1}^n \text{Var}(X_i)$$

Since using the result number 2 covariance of X comma Y that is a means covariance of Y comma X ; that means, the second summation can be rewritten in the form of a 2 times double summation. Covariance of X_i with X_j ; now the condition is instead of i is not equal to j I can write i is less than j because we have put the 2 times. So, both the statements are one and the same.

Here also we can go for one special case, suppose X_i 's are independent random variables independent, when I say independent random variables; that means, they are mutually independent random variable. In that case we can use the previous result that is result number 5.

(Refer Slide Time: 03:35)

(5) Suppose X & Y are Independent r.v.s
we know that
$$F_{X,Y}(x,y) = F_X(x)F_Y(y)$$
$$\text{Cov}(X,Y) = E(XY) - E(X)E(Y)$$
$$E(XY) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} xy f_{X,Y}(x,y) dx dy$$
$$= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} xy f_X(x) f_Y(y) dx dy$$

Well any 2 random variables are independent then the covariance is going to be 0. Therefore, the second the summation whole thing; it will not come therefore, variance of sum of a random variables is same as sum of variance of individual random variables when X i's are mutually independent random variables.

(Refer Slide Time: 04:18)

Definition Expected value of a random Vector
Let $X = (X_1, X_2, \dots, X_n)$ be a n -dim r.v.s.
The expected value of X , $E(X)$, is defined as
$$E(X) = (E(X_1), E(X_2), \dots, E(X_n))$$

provided the $E(X_i)$'s exist, for $i=1, 2, \dots, n$

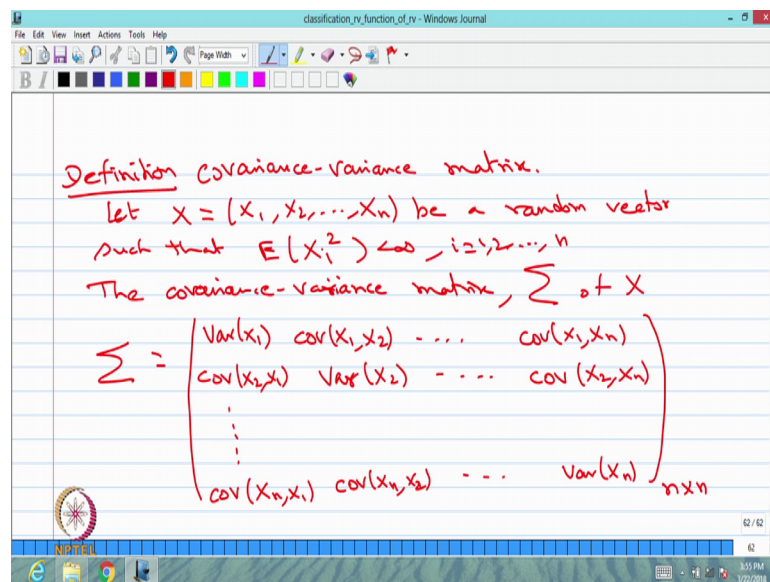

Now, we will give the definition of a expected value of a random vector; we have already given the definition of expected value of function of random vector. Now we are going to

give the definition of expected value of a random vector; let X_1, X_2, \dots, X_n be a n dimensional random variables.

The expected value of X ; let me denote this random vector in the form of capital X , let me denote X_1, X_2, \dots, X_n random vector with a notation capital X . So, I am going to define the expected value of the random vector capital X , which is denoted by expectation of X is defined as; it is defined as expectation of X is nothing, but since X_1, X_2, \dots, X_n 's are vector the expected value of X is also going to be vector; whose elements are expectation of X_1 , expectation of X_2 and so, on expectation of X_n .

We are finding the expected value of a random vector therefore, that is also going to be a vector whose elements are expected value of individual random variables; provided the expectation of X_i 's exist for i is equal to $1, 2, \dots, n$. So, as long as a individual expectation exists one can define expected value of a random vector with the elements is X_1, X_2, \dots, X_n . In the same way we are going to create a matrix whose elements are variance and the covariance between any 2 random variable that is a next definition.

(Refer Slide Time: 07:32)

The next definition is covariance variance matrix; let capital X it is a random vector for the random variables X_1, X_2 and so, on; X_n be a random vector either you can say random vector or n dimensional random variables or random vector with the n random variables. Such that the expectation of X_i square that is a finite for the random variable $1, 2$ so on till n as long as the second order moment exist.

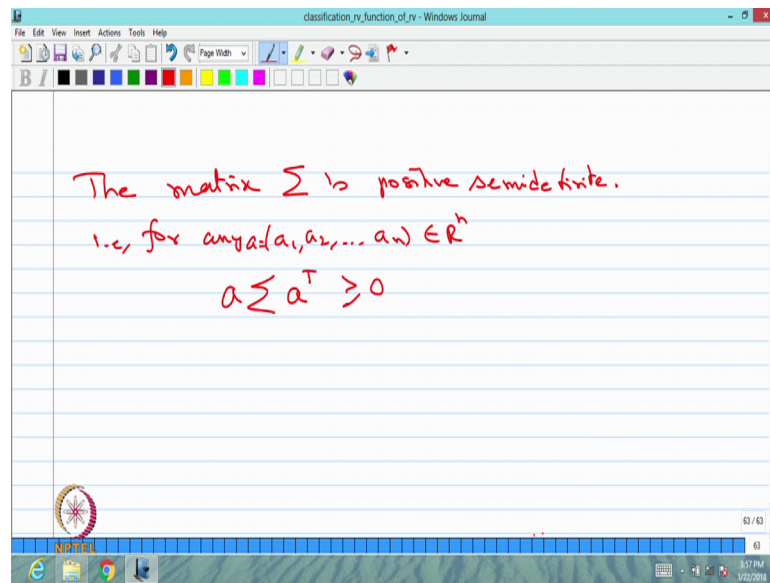

One can go for, one can go for defining covariance variance matrix. Then the covariance variance matrix that is denoted by in the big summation notation of the random variable capital X. That is defined as it is in the big summation notation it is a matrix whose elements are; the first element is variance of X_1 and the first row second element it is a covariance of X_1 and X_2 like that so, on the first row the last element that is covariance of X_1 with X_n .

Now, coming to the second row; second row is covariance of X_2 with X_1 , second row second element that is diagonal element that is variance of X_2 ; like that you can keep writing. The last element in the in the second row, that is covariance of X_2 with X_n like that you can fill up the last row with the first column that is X_n with X_1 . The last row second column that is X_n with X_2 so on the last row last element that is a diagonal element that is variance of X_n .

So, this matrix is n cross n order; we are creating a covariance variance matrix for n dimensional random variable. Therefore, this matrix is always n cross n whose diagonal elements are covariance of individual random variables and the other elements are covariance of X_i into X_j for the i th row and j th column.

By using the property of covariance of X comma Y is same as covariance of Y comma X ; you can conclude that this matrix is a symmetric matrix. All the diagonal elements are the variance that is nothing, but covariance of X_i 's with the X_i 's; therefore, it is becomes a variance of X_i 's.

(Refer Slide Time: 11:53)

So, this matrix has the very important property that is the matrix is positive semi definite; that means, for an $a = (a_1, a_2, \dots, a_n) \in \mathbb{R}^n$ the vector. Suppose I denote this as the vector a suppose I denote this as the vector a suppose I denote this as a vector a whose elements are a_1, a_2, \dots, a_n ; belonging to \mathbb{R}^n , a vector multiplied by the matrix; then a vector transpose this value is always going to be greater or equal to 0. That is called the matrix is positive semi definite, the covariance variance matrix of random vector is always positive semi definite.

We will give a one simple example; how to compute the expected value of a random vector and covariance variance matrix.

(Refer Slide Time: 13:23)

The screenshot shows a Windows Journal window titled "classification_of_function_of_rv - Windows Journal". The content is handwritten in red ink on a lined background. It starts with "Example Let $x = (x_1, x_2)$ be a random vector with joint pdf". Below this is the joint probability density function:
$$f_{x_1, x_2}(x_1, x_2) = \begin{cases} \frac{1}{x_1}, & 0 < x_1 < 1, 0 < x_2 < x_1 \\ 0, & \text{otherwise} \end{cases}$$
 At the bottom, there is a list of problems to find: (1) $E(x_1)$, (2) $E(x_2)$, (3) $E(x_1^2)$, (4) $E(x_2^2)$, (5) $E(x_1 x_2)$, (6) $E(x)$, (7) Σ , and (8) $a \Sigma a^T \geq 0$.

Example let capital X is the vector whose elements are X_1 comma X_2 ; be a random vector with joint probability density function is given by ; that means, both the random variables X_1 and X_2 are continuous type random variable. Therefore, we are defining the joint probability density function of x_1 comma x_2 ; that is 1 divided by x_1 ; when x_1 takes a value 0 to 1 whereas, x_2 takes the value 0 to x_1 ; 0 otherwise. So, this is the joint probability density function of the random vector X_1 comma X_2 . You can verify double integration of a joint probability density function has to be 1.

Let us find expectation of X_1 , then we will go for finding expectation of X_2 , then we can go for finding expectation of X_1 square, then you can go for expectation of X_2 square, then we can go for expectation of $X_1 X_2$, then we can go for expected value of the vector X . We can find out what is the covariance, variance matrix then we can go for verifying whether it satisfies a summation; a transpose is greater or equal to 0.

The last one is the, verify a times matrix a transpose is greater or equal to 0. So, all those things we can do one by one.

(Refer Slide Time: 16:22)

The screenshot shows a Windows Journal window with the following handwritten equations:

$$E(X_1) = \int_0^1 \int_0^{x_1} x_1 \frac{1}{x_1} dx_2 dx_1 = \frac{1}{2}$$
$$E(X_2) = \int_0^1 \int_0^{x_1} x_2 \frac{1}{x_1} dx_2 dx_1 = \frac{1}{4}$$
$$E(X_1^2) = \int_0^1 \int_0^{x_1} x_1^2 \frac{1}{x_1} dx_2 dx_1 = \frac{1}{3}$$
$$E(X_2^2) = \int_0^1 \int_0^{x_1} x_2^2 \frac{1}{x_1} dx_2 dx_1 = \frac{1}{9}$$

First start with the expectation of X_1 ; expectation of X_1 , you can find the probability density function of X_1 from the joint probability density function, then you can go for the expectation or you can use the first definition that is expected value of function of a random vector. So, we are going to use that that is same as integration from 0 to 1, integration from x_2 to 1, x_1 ; 1 divided by x_1 , dx_1 , dx_2 . You see that the joint probability density function is 1 divided by x_1 where x_1 is range from 0 to 1 whereas, x_2 range is 0 to x_1 .

Therefore expectation of X_1 is double integration 0 to 1 x_2 to 1 x_1 times 1 divided by x_1 divided by x_1 is a joint probability density function of x_1 , x_2 . If you do the simplification we will get the answer 1 by 2; similarly you can go for finding expectation of X_2 ; that is integration 0 to 1 0, to x_1 ; x_2 times the joint probability density function, integration with respect to x_2 , integration with respect to x_1 .

Again I am using the expected value of function of a random vector; this is same as 1 divided by 4. Similarly we can go for expectation for X_1 square; that is same as same method what I have done it for expectation of X_1 that is integration 0 to 1 integration x_2 to 1 x_1 square, the joint probability density function is 1 divided by x_1 dx_1 , dx_2 or you can use the change of integration and you can change the order of integration still you can go for it and you can get the answer that is 1 by 3.

Similarly, you can go for expectation of X_2 square that is again 0 to 1, 0 to x_1 x 2 square 1 divided by $x_1 dx_2 dx_1$; I am using the same definition again that is same as 1 divided by 9. So, till now we have got expectation of X_1 , expectation of X_2 , expectation of X_1 square, expectation of X_2 square.

(Refer Slide Time: 19:56)

The image shows a handwritten derivation in a software window titled 'classification.rv.function.of.rv - Windows Journal'. The derivations are as follows:

$$E(X_1, X_2) = \int_0^1 \int_0^{x_1} x_1 x_2 \cdot \frac{1}{x_1} dx_2 dx_1 = \frac{1}{6}$$

$$E(X) = (E(X_1), E(X_2)) = \left(\frac{1}{2}, \frac{1}{4}\right)$$

$$\Sigma = \begin{pmatrix} \text{Var}(X_1) & \text{cov}(X_1, X_2) \\ \text{cov}(X_1, X_2) & \text{Var}(X_2) \end{pmatrix} = \begin{pmatrix} \frac{1}{12} & \frac{1}{24} \\ \frac{1}{24} & \frac{7}{144} \end{pmatrix}$$

Now, we will go for finding expectation of X_1 , X_2 ; the same technique that is expectation of X_1 , X_2 that is same as integration 0 to 1, integration 0 to x_1 , x_1 , x_2 multiplied by the joint probability density function dx_2, dx_1 . If you do the simplification you will get the answer that is 1 by 6.

So, now we are going for the next result that is expectation of a random vector; that is a vector whose elements are expectation of X_1 comma expectation of X_2 ; this vector. That is same as already we got the result expectation of X_1 is 1 by 2 expectation of X_2 is 1 by 4; therefore, this vector is 1 by 2 comma 1 by 4.

The next is finding the covariance variance matrix, since we have only 2 random variables which is going to be 2 cross 2 whose elements are variance of X_1 , covariance of X_1 with X_2 , covariance of X_2 with X_1 or X_1 with X_2 both are one and the same and variance of X_2 . That is same as we got the expectation of X_1 and expectation of X_1 square. So, the variance is expectation of X_1 square minus expectation of X_1 whole square. So, if you do the simplification we will get the answer 1 by 12.

To find the covariance of X_1, X_2 you need expectation of $X_1 X_2$ and expectation of X_1 and expectation of X_2 ; so, all 3 we got it. So, substitute the values, that is 1 by 6 minus 1 by 2 into 1 by 4. So, you simplify you will get the answer that is 1 by 24. Since covariance of $X_1 X_2$ is 1 by 24 that is again a covariance of X_2 comma X_1 that is same as covariance of X_1 comma X_2 that is 1 divided by 24. Variance of X_2 is expectation of X_2 square minus expectation of X_2 , the whole square. So, you do the simplification you will get 7 divided by 144. So, this is the covariance variance matrix for the random vector $X_1 X_2$.

Now, we are going to verify whether this covariance variance matrix satisfies the condition a covariance variance matrix a transpose going to be greater than or equal to 0.

(Refer Slide Time: 23:02)

$$\begin{aligned}
 a \sum a^T &= (a_1, a_2) \sum \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} \\
 &= (a_1, a_2) \begin{pmatrix} \frac{1}{12} & \frac{1}{24} \\ \frac{1}{24} & \frac{7}{144} \end{pmatrix} \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} \\
 &= \frac{1}{12} \left(a_1^2 + a_1 a_2 + \frac{1}{4} a_2^2 - \frac{1}{4} a_2^2 + \frac{7}{12} a_2^2 \right) \\
 &= \frac{1}{12} \left(a_1 + \frac{a_2}{2} \right)^2 + \frac{1}{36} a_2^2 \geq 0
 \end{aligned}$$

Let us compute; so, here we will go for a, with the 2 elements, a_1 comma a_2 and the matrix transpose that is a_1, a_2 . So, substitute the, that is a_1 comma a_2 and the matrix value is 1 by 12, 1 by 24, 1 by 24, 7 divided by 144 multiplied by a_1, a_2 transpose vector.

Do the simplification, do the simplification first you will get 1 by 12, a_1 square plus a_1, a_2 plus 1 by 4 a_2 square minus 1 by 4, a_2 square plus 7 by 12, a_2 square and this is same as 1 by 12 a_1 plus a_2 divided by 2 whole square plus 1 by 36, a_2 square which is greater than or equal to 0. Therefore, we are concluding this particular covariance variance matrix also positive semi definite.
