(Refer Slide Time: 00:08)

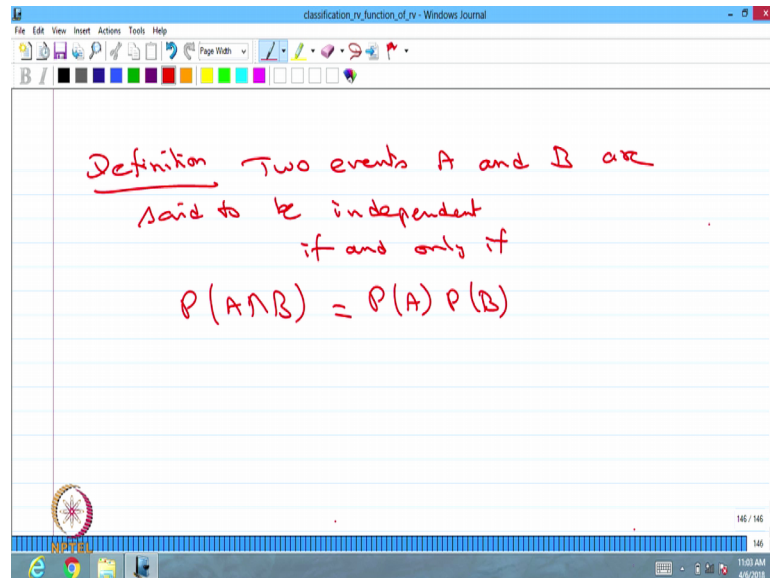

Now, we will move into the next topic that is called conditional probability. Let (Ω, \mathcal{F}, P) be a probability space, we are not making any assumption over this probability space. If A, B belonging to \mathcal{F} both are events with the P of A is greater than 0; that means, it is not impossible events impossible events means the probability with that event is equal to 0 and, sure event means the probability of A that event is equal to 1, rare event means the probability of A that event is open interval between 0 to 1 so, here it is a non impossible event.

Then the probability of the event B , under the condition the event A , that is defined as $P(B/A)$ of event B slash event A that is same as $P(A \cap B)$ divided by $P(A)$, this is well defined, because the probability of A is strictly greater than 0.

So, this condition probability is going to be probability of B given A is same as probability of $A \cap B$ divided by probability of A , this is called the conditional probability of event B given event A few properties on the conditional probability, but

before that let me give the definition of independent events, then I will come to the results on the conditional probability.

(Refer Slide Time: 02:43)

The first definition two events A and B are said to be independent if, and only if the intersection probability is same as the product of the individual probabilities.

We say if and only if condition, whenever this condition is satisfied by any two events, then we call it as both the events are independent. If two events are independent, then this condition will be satisfied, based on this I am going to give a two definition, we always called pair wise independent and other one is called mutual independent.

(Refer Slide Time: 03:45)

The screenshot shows a Windows Journal window titled "classification_rv_function_of_rv - Windows Journal". The journal page contains the following handwritten text in red ink:

Definition Pairwise Independent Events
A sequence of events $\{A_i, i=1, 2, \dots\}$ is said to be pairwise independent if
$$P\{A_i \cap A_j\} = P(A_i)P(A_j) \text{ for all } i \neq j$$

Then its definition that is a pair wise independent events A sequence of A events A_i , where i is equal to 1 2 so on is said to be pair wise independent. If you take any two events that satisfies the independent property, that is a P of A_i intersection A_j that is same as P of A_i into P of A_j , for all i is not equal to j .

So, if you take any two events that satisfies the independent condition, then we conclude this sequence of events or this collection of events are called pairwise independent, if it satisfies the independent condition.

(Refer Slide Time: 05:08)

The screenshot shows a Windows Journal window titled "classification_rv_function_of_rv - Windows Journal". The journal page contains the following handwritten text in red ink:

Definition Mutually Independent Events
A sequence of events $\{A_i, i=1, 2, \dots\}$ is said to be mutually independent if and only if
for any finite sub collection A_1, A_2, \dots, A_k
$$P(A_1 \cap A_2 \cap \dots \cap A_k) = P(A_1)P(A_2) \dots P(A_k)$$

for all k

The next definition, that is mutually independent events, A sequence of events, A_i 's is said to be said to be mutually independent, mutually independent. If and only if for any finite, for any finite sub collection that is a $A_1 A_2$ so, on A_k .

The probability of A_1 intersection A_2 and so, on intersection A_k that is same as P of A_1 multiplied by P of A_2 and so on, P of A_k for all k , that is very important that means, if you take a k equal to 2, so if you take any 2 events in this collection that satisfies independent property, or independent condition. Or, if you take any 3 events that also satisfies the independent condition, like that if you take all the possible number of events, that is the sub collection from that collection of events, satisfies the independent property. Then we conclude: they are mutually independent events sometimes, we would not use the word mutually, if you say that a few events are independent; that means, by default they are mutually independent events.

You see the previous definition that is the pairwise independent events, but that is satisfied only for any two events not 3 or 4 or 5 independence properties not going to be satisfied; that means, the mutual independent events implies their pairwise independent, but the pairwise independent need not imply the mutual independent events, for the collection of a events.

(Refer Slide Time: 08:00)

Example Let $\Omega = \{1, 2, 3, 4\}$
 Let $A = \{1, 2\}$
 $B = \{1, 3\}$
 $C = \{1, 4\}$
 Assume that $P(\{w\}) = \frac{1}{4}$, $w = 1, 2, 3, 4$
 $A \cap B = \{1\} = A \cap C = B \cap C = A \cap B \cap C$
 $P(A) = \frac{1}{2}$, $P(B) = \frac{1}{2}$, $P(C) = \frac{1}{2}$

So, let us go for one simple example for pairwise independent and mutual independent, then we will move into the properties on the condition property, so the example as

follows. Let ω consisting of 1 2 3 4. Let A be the event consisting of only two elements 1 and 2.

Similarly P is the element consisting of 1 and 3 and C is the element consisting of 1 and 4. And we assume that we assume that the probability of singleton element w that is equal to 1 divided by 4, for w is equal to either 1 or 2 or 3 or 4.

Now, we will verify whether this event satisfies the pairwise independent as well as mutual independent, or only satisfies pairwise independent not the mutual independent. Let us go for finding A intersection B that is nothing, but the sample one. And similarly if you go for A intersection C that is also singleton element 1.

If you go for A intersection B intersection C that is also single element 1, where as you compute the P of A that is 2 by four that is 1 by 2 and P of B that is also 2 by 4, that is 1 by 2 and P of C P of C, that is also again 2 by 4 that is 1 by 2.

(Refer Slide Time: 10:11)

The image shows a handwritten derivation in a software window titled "classification_rv_function_of_rv - Windows Journal". The text is written in red ink on a lined background. It shows the following calculations:

$$P(A \cap B) = \frac{1}{4} ; P(A \cap C) = \frac{1}{4} ; P(B \cap C) = \frac{1}{4}$$

$$P(A \cap B \cap C) = \frac{1}{4}$$

$$P(A)P(B)P(C) = \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} = \frac{1}{8} \neq P(A \cap B \cap C)$$

$$P(A \cap B) = \frac{1}{4} = P(A)P(B)$$

A, B & C are pairwise Independent events
But They are not mutually Independent events.

Now, if you compute P of A intersection B that is also 1 by 4. Similarly if you compute B of A intersection C that is also 1 by 4; similarly, P of A intersection C that is also 1 by 4 whereas, P of A intersection B intersection C that is also 1 by 4.

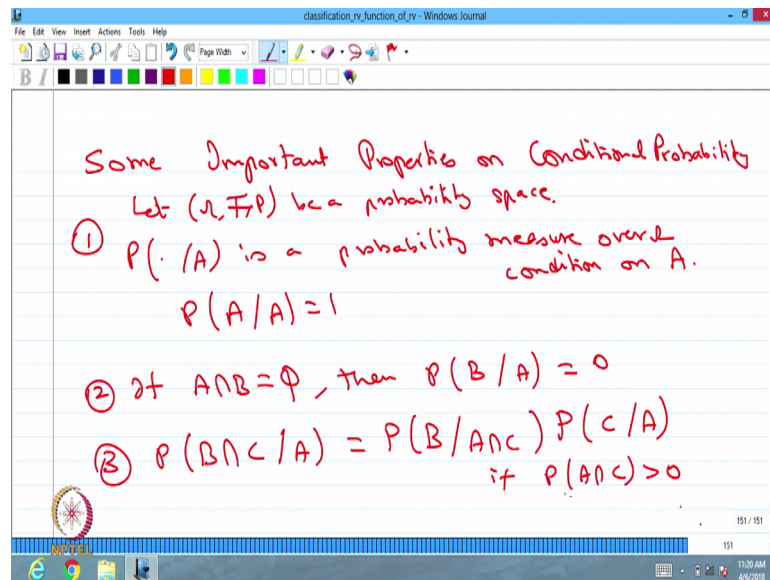

For example if you test P of A into P of B into P of C that is going to be 1 by 2 into 1 by 2 into 1 by 2 that is 1 by 8, which is not same as P of a intersection B intersection C.

Whereas A if you go for P A intersection B that is same as 1 by 4, that is same as a P of a into P of B.

Similarly, probability of a intersection C that is same as P of A into P of C. Similarly P of B intersection C that is same as B into P of C that means, it satisfies the independent condition for any two events not for the all 3 events that means, in this example A B and C, or pair wise independent events.

But they are not mutually independent events, because it does not satisfies independent property for three events. So, this very simple example conclude pairwise does not imply the mutually independent events in general.

(Refer Slide Time: 12:32)

Now, let us go for some properties on condition property, some important properties on conditional probability. The first one so, before that we have probability space, let omega capital F P P F probability space, in that probability space we going to give the properties the first one, P of the conditional probability that is probability measure.

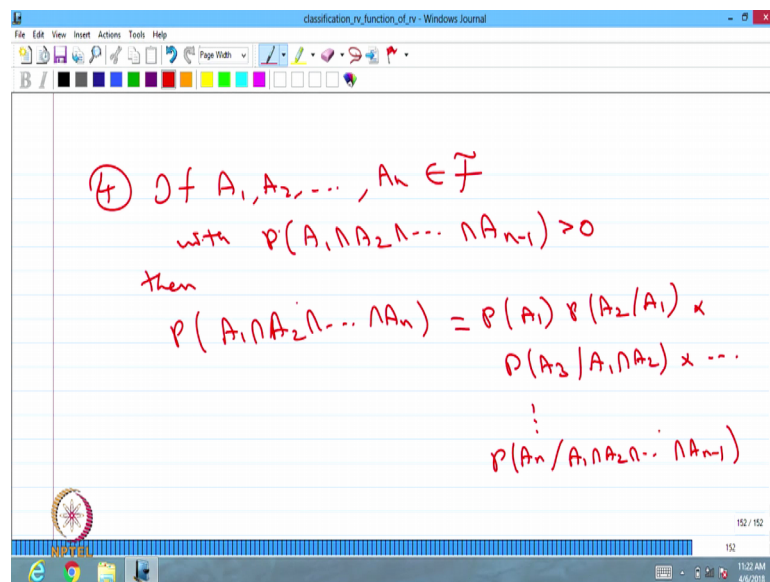

The condition probability that is also a probability measure over omega condition on the event A that means, it satisfies the axiomatic properties of the probability, that is a three properties P of A's is are always greater than or equal to 0 for all A belonging to F. And P of empty set P of whole set is 1 and, mutually disjoint events P of union is same as a submission of P of S.

The same thing here also satisfied here, the P of A given A that is going to be 1, where as in the axiomatic definition probability the P of omega is 1 here, the condition probability that is also probability space here P of A given A that is equal to 1. Second important property that is if A intersection B is empty set, then the condition probability of event B given A that is doing to be because same as probability of B intersection A divided by probability of A.

Since, A intersection B is empty set P of empty set is 0 therefore, probability of B given a that is equal to 0, third result or third property P of B intersection C given A, that is same as the conditional probability of event B, given A intersection C multiplied by P of event C given A. If probability of A intersection C is larger than 0.

Whenever you want to compute a probability of B interaction C given A, that can be computed in the form of probability of B given a intersection C multiplied by P of that is multiplied by probability of event to C given A, whenever probability of A intersection C is greater than 0.

(Refer Slide Time: 16:16)

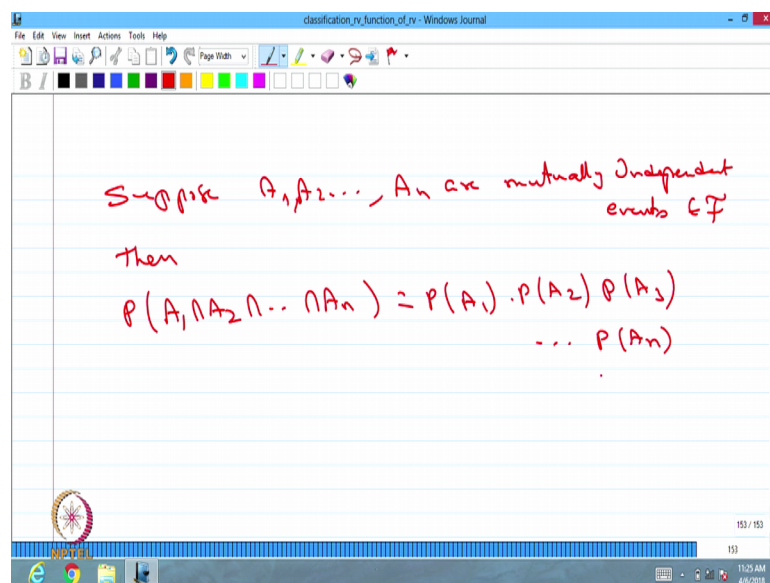

The next result related to the conditional probability. If A 1 A 2 and so on, A n n events belonging to F with probability A 1 intersection A 2 intersection, A n minus 1, if that probability is t larger than 0.

Then one can define probability of intersection of n events the assumption is A intersection of A_{n-1} events probabilities greater than 0, we have n events belong F . Then one can find the probability of intersection of n event is same as probability of A_1 multiplied by probability of A_2 , given A_1 multiplied by probability of A_3 given A_1 intersection A_2 , multiplied by the same way. The last element is probability of A_n given A_1 intersection A_2 intersection so on, intersection A_{n-1} .

This is possible whenever you have n events and, the probability of intersection of n events provided probability of intersection of $n-1$ events is greater than 0, one can always find the product of condition probability with the intersection of the events. This is valid for any countable number of events satisfying this condition, there no assumption over the events to apply this result.

Now, suppose these events are mutually independent, or mutually independent events, then the results are going to be day simplified as follows.

(Refer Slide Time: 18:34)

That means, suppose A_1, A_2, A_n are mutually independent events, all are belonging to F suppose, this events are mutually independent event belonging to F .

Then the P of A_1 intersection A_2 intersection and so on, A_n that is same as, we are retaining the other condition intersection of P of A_{n-1} intersection A_{n-2} intersection A_{n-3} intersection A_{n-4} intersection A_{n-5} intersection A_{n-6} intersection A_{n-7} intersection A_{n-8} intersection A_{n-9} intersection A_{n-10} intersection A_{n-11} intersection A_{n-12} intersection A_{n-13} intersection A_{n-14} intersection A_{n-15} intersection A_{n-16} intersection A_{n-17} intersection A_{n-18} intersection A_{n-19} intersection A_{n-20} intersection A_{n-21} intersection A_{n-22} intersection A_{n-23} intersection A_{n-24} intersection A_{n-25} intersection A_{n-26} intersection A_{n-27} intersection A_{n-28} intersection A_{n-29} intersection A_{n-30} intersection A_{n-31} intersection A_{n-32} intersection A_{n-33} intersection A_{n-34} intersection A_{n-35} intersection A_{n-36} intersection A_{n-37} intersection A_{n-38} intersection A_{n-39} intersection A_{n-40} intersection A_{n-41} intersection A_{n-42} intersection A_{n-43} intersection A_{n-44} intersection A_{n-45} intersection A_{n-46} intersection A_{n-47} intersection A_{n-48} intersection A_{n-49} intersection A_{n-50} intersection A_{n-51} intersection A_{n-52} intersection A_{n-53} intersection A_{n-54} intersection A_{n-55} intersection A_{n-56} intersection A_{n-57} intersection A_{n-58} intersection A_{n-59} intersection A_{n-60} intersection A_{n-61} intersection A_{n-62} intersection A_{n-63} intersection A_{n-64} intersection A_{n-65} intersection A_{n-66} intersection A_{n-67} intersection A_{n-68} intersection A_{n-69} intersection A_{n-70} intersection A_{n-71} intersection A_{n-72} intersection A_{n-73} intersection A_{n-74} intersection A_{n-75} intersection A_{n-76} intersection A_{n-77} intersection A_{n-78} intersection A_{n-79} intersection A_{n-80} intersection A_{n-81} intersection A_{n-82} intersection A_{n-83} intersection A_{n-84} intersection A_{n-85} intersection A_{n-86} intersection A_{n-87} intersection A_{n-88} intersection A_{n-89} intersection A_{n-90} intersection A_{n-91} intersection A_{n-92} intersection A_{n-93} intersection A_{n-94} intersection A_{n-95} intersection A_{n-96} intersection A_{n-97} intersection A_{n-98} intersection A_{n-99} intersection A_n that is probability is greater than 0, we are keeping that in P of A_1 , intersection A_2 , intersection

A_n . That is same as you see the previous one, first one is P of A_1 , the second $1 P$ of A_2 given A_1 . Since A_1 and A_2 and A_n 's are mutually independent events the intersection.

The condition probability A_2 given A_1 that is going to be a probability upon A_2 therefore, this is going to be probability of A_2 . Similarly, probability of A_2 given A_1 interaction A_2 that is again to be probability A_3 and so on; the last one it is P of A that means, if events are mutually independent, then the intersection probability same as the product of individual probabilities. So, this can be proved also; so I am just using that result.
