Lecture – 43

Now, we will discuss the third mode of convergence that is convergence in r th moment.

(Refer Slide Time: 00:09)

Let, r greater than 0 x_1, x_2 and so on x_n and so on be a sequence of random variables defined on ω F capital P such that the r th moment for the sequence of random variable is exist; the absolute sense expectation is going to be finite for n is equal to 1, 2 and so on.

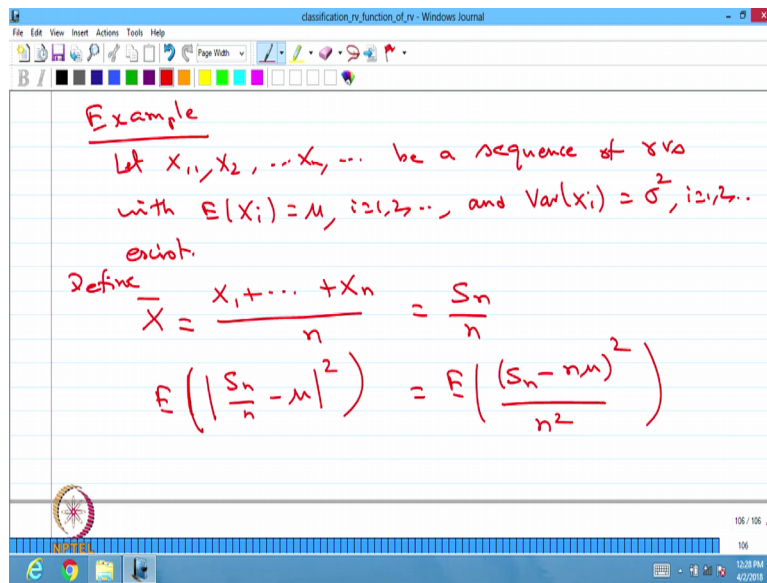

We say that, we say that this sequence of random variable converges to the random variable X in r th moment, if the expectation of the random variable X the r th moment that is finite and X also defined in the same probability space of course.

And limit n tends to infinity; limit n tends to infinity expectation of in absolute sense X_n minus X to the power r that expected quantity is going to be 0. We are keeping r greater than 0 and we have a sequence of random variable defined in the probability space such that r th moment exist for those sequence of random variable.

We say that the sequence of random variable converges to X in r th moment provided the r th moment exist for the random variables X , which is defined in the same probability space and the limit n tends to infinity expectation that difference of this random variable, the r th moment is going to 0.

If these conditions are satisfied, then we can conclude the sequence of random variable converges to the random variable in the r th moment.

(Refer Slide Time: 03:27)

We can go for the example to explain this mode of convergence also. That is let X_1, X_2, X_n and so on be a sequence of random variables with mean μ ok, identical μ and variance of each random variable that is σ^2 or exist both exist and is denoted by μ for the mean and variance is σ^2 . I am going to define the new random variable that is sum of n random variables divided by n ; sum of random variable we usually use the notation S_n .

But now, I am going to divide that sum divided by n . So, I am going to use a notation called \bar{X} . \bar{X} is the random variable; it is a function of n . I am not writing n in the left side, \bar{X} is the sum of random variables divided by n fine or we can another notation we can use as a function of S . S_n divided as a function of n . S_n divided by n . Either I can use \bar{X} or S_n divided by n , both are one and the same that is sum of random variable. So, this is the.

So, I am going to define this random variable for different n will go for finding first expectation of expectation of absolute of S_n by n minus μ the whole square. In absolute sense, we will find what is the value of S_n by n minus μ square in absolute sense that is same as expectation of S_n is the square S_n minus n μ divided by S_n minus n μ whole square divided by n square.

(Refer Slide Time: 06:42)

The image shows a handwritten derivation in a software window titled "classification_rv_function_of_rv - Windows Journal". The derivation is as follows:

$$= \frac{1}{n^2} \text{Var}(S_n) \quad (\because E(S_n) = n\mu)$$

$$= \frac{1}{n^2} \cdot n\sigma^2$$

$$= \frac{\sigma^2}{n}$$

$$E\left(\left|\frac{S_n}{n} - \mu\right|^2\right) = \frac{\sigma^2}{n}$$

$$\lim_{n \rightarrow \infty} E\left(\left|\frac{S_n}{n} - \mu\right|^2\right) = 0$$

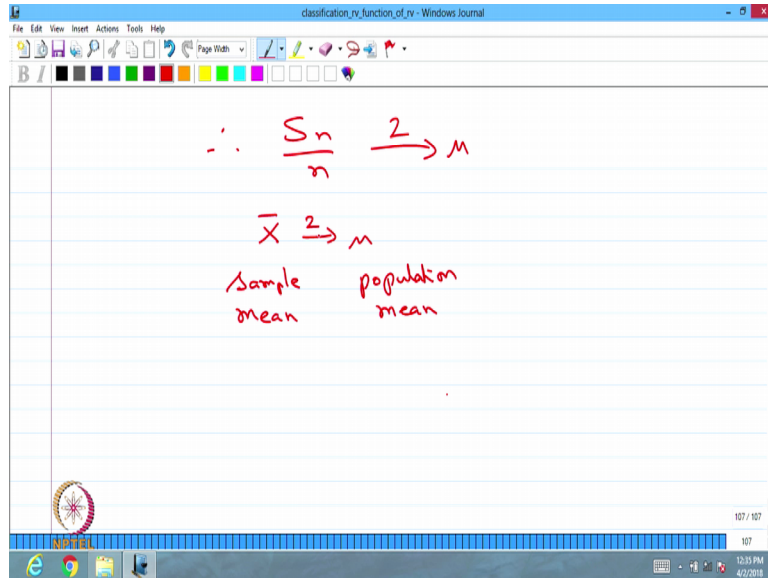

That is same as, I can take 1 by n square outside, if you see S_n minus n μ whole square expectation. If you find out the expectation of S_n expectation of S_n that is the expectation of X_1 plus X_2 plus X_n all the expectation of X_i 's are same that is μ . Therefore, it is n μ .

So, since expectation of S_n is n μ . So, the expectation of S_n minus n μ whole square is nothing but variance of S_n ; that is same as 1 divided by n square. I will make a additional condition X is are sequence of independent random variable with the mean is μ and the variance is σ square.

Therefore, the variance of S_n is nothing, but variance of X_1 plus X_2 plus so on plus X_n and variance of X is or σ square. Therefore, it is going to be n σ square. Therefore, this is going to be σ square by n . We got the expectation of absolute of S_n by n minus μ whole square that is going to be σ square by n .

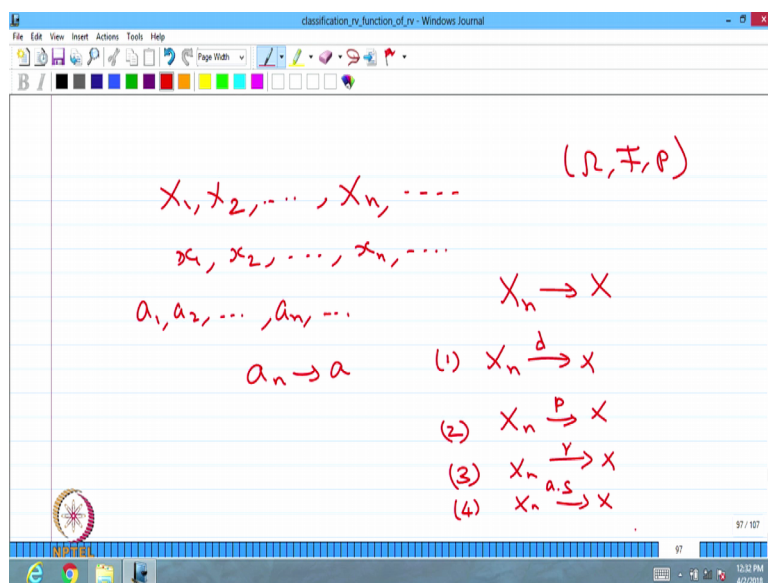

Now, let me apply limit n tends to infinity of expectation of absolute of S_n by n minus μ the whole square. Since, n is in the denominator this becomes 0.

(Refer Slide Time: 08:42)

So, this is the definition we wanted to convergence in r th moments; that means, I can conclude, S_n by n converges to μ in second order moment. The left right hand side it is not a random variable, it takes a value μ ; that means it is a random variable takes a value μ with the probability 1.

(Refer Slide Time: 09:12)

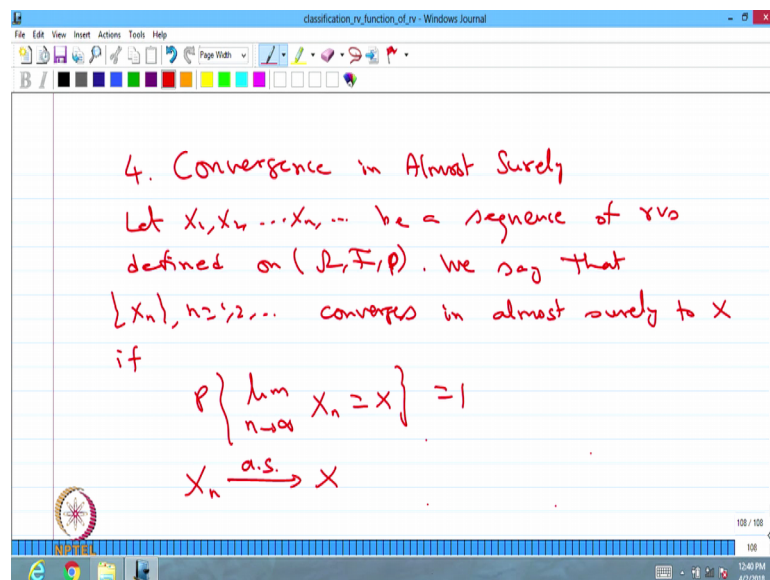

So, X_n converges to r th moment with number r . In notation, we write S_n by n converges to μ in the second order moment. In the right hand side μ means it is a random variable takes a value μ with the probability 1. I have already written X_n by n as the \bar{X} . So, \bar{X} converges to μ in second order moment.

In statistics we use the \bar{X} that is sum of random variable divided by n that is from the n random variable we call it as a Sample mean the sequence of random variable having the mean μ , variance σ^2 . So, the μ is called Population mean. So, the conclusion is if you have a population with the mean μ and if you get a sample of size n , then the sample mean will converge to the population mean as n tends to infinity.

That means, if you for a large sample or a large sample the sample mean will converge to the population mean and this converges takes place in the convergence in r th moment, where r is equal to 2 here. Because we are finding the second order moment convergence is used. Therefore, sample mean converges to the population mean in second order moment.

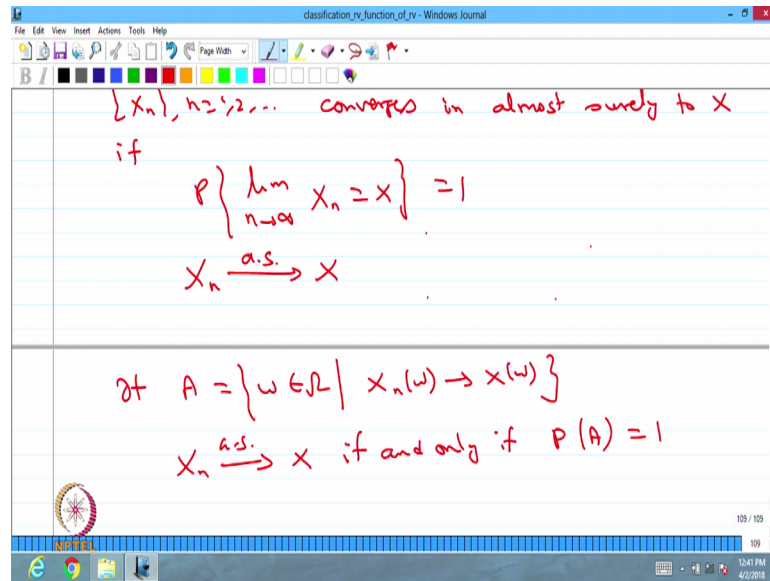

(Refer Slide Time: 11:18)

We move to the fourth mode of convergence; convergence in Almost Surely. Let X_1, X_2, \dots, X_n and so on be a sequence of random variables defined on the probability space Ω, \mathcal{F}, P . We say that the sequence converges; the sequence converges in almost surely to the random variable X , if the probability of limit n tends to infinity. X_n is equal to X that is 1.

So, here the random variable X is defined in the same probability space. The probability of limit n tends to infinity X_n is equal to X that is going to be 1, then one can conclude the sequence of random variable convergence to the random variable X in almost surely. So, we write it X_n converges to X above the arrow, you write a dot S ; that means, this convergence in almost surely.

(Refer Slide Time: 13:42)

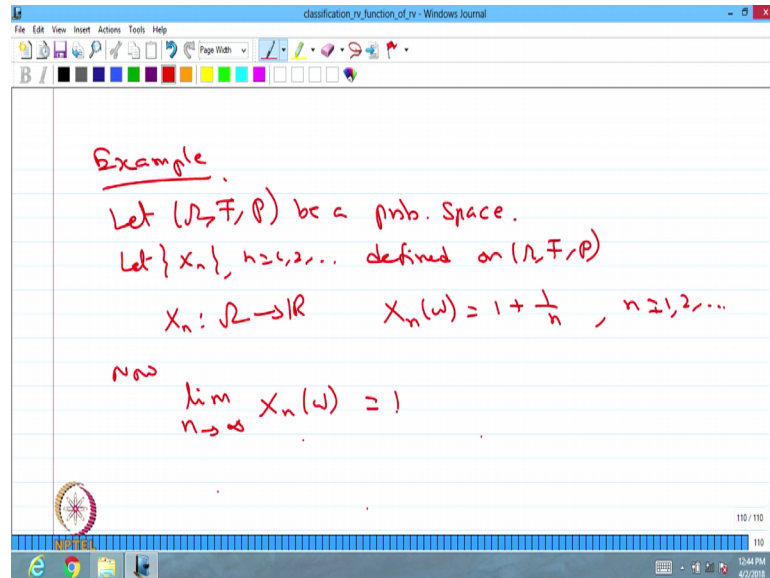

Suppose, we make a suppose we make a event A is nothing but collection of w 's belonging to Ω such that X_n of w tends to X of w . In that case when I say X_n converges to X almost surely, if and only if the probability of the event A that is going to be 1. If I make a event A that is nothing but as n tends to infinity X_n of w will tends to X of w and collect those w 's that is going to be the event A . If the probability of that event A is going to be 1; then, we can conclude the X_n converges to X almost surely.

In other words, negation of the event A that probability is going to be 0; that means, you collect all possible outcomes from Ω which does not converge X_n of w to the X of w , you collect those possible outcomes whose measure is 0. Then, we also we can conclude X_n converges to X almost surely; that means, it is the whole unit mass is attached with the collection of possible outcomes; those outcomes or the outcomes of X_n of w converges to X of w .

Those outcome satisfies X_n of w converges to r tends to X of w as n tends to infinity. So, if you include those possible outcomes or w 's those possible outcomes whose

probability mass is 1 or whichever is not satisfy in this condition, those possible outcomes whose probability mass is 0. Then we can conclude X_n converges to X in almost surely. We will go for the example for this.

(Refer Slide Time: 16:07)

The screenshot shows a Windows Journal window titled "classification_rv_function_of_rv - Windows Journal". The window contains handwritten text in red ink on a lined background. The text reads: "Example", "Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a prob. space.", "Let $\{X_n\}, n=1,2,\dots$ defined on $(\Omega, \mathcal{F}, \mathbb{P})$ ", " $X_n: \Omega \rightarrow \mathbb{R} \quad X_n(\omega) = 1 + \frac{1}{n}, n=1,2,\dots$ ", and "Now $\lim_{n \rightarrow \infty} X_n(\omega) = 1$ ". The window also shows a standard Windows taskbar at the bottom with icons for Internet Explorer, Google Chrome, and other applications, along with the system clock showing 1:44 PM on 4/22/2018.

Let Ω, \mathcal{F} and \mathbb{P} be a probability space. Let sequence of random variable defined on the probability space $\Omega, [\mathcal{F}], \mathbb{P}$ as X_n of X_n is mapping from Ω to real line such that X_n of ω is equal to $1 + \frac{1}{n}$ for n is equal to $1, 2$ and so on.

Now, will go for computing limit n tends to infinity X_n of ω where ω is belonging to Ω . make a limit; n tends to infinity of X_n of ω that is going to be 1 .

(Refer Slide Time: 17:25)

The image shows a screenshot of a Windows Journal window titled "classification_of_function_of_ny - Windows Journal". The window contains handwritten mathematical text in red ink on a lined background. The text is as follows:

Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a prob. space.
Let $\{X_n\}, n=1,2,\dots$ defined on $(\Omega, \mathcal{F}, \mathbb{P})$
 $X_n: \Omega \rightarrow \mathbb{R} \quad X_n(\omega) = 1 + \frac{1}{n}, n=1,2,\dots$
Now, for all $\omega \in \Omega$
 $\lim_{n \rightarrow \infty} X_n(\omega) = 1$
 $\mathbb{P}\{\omega \in \Omega \mid X_n(\omega) \rightarrow 1\} = \mathbb{P}(\Omega) = 1$
 $\therefore X_n \xrightarrow{\text{a.s.}} 1$

That means, the set of all ω 's belonging to Ω such that X_n of ω will tend to 1. You collect those possible outcomes find out the probability of that that is nothing but \mathbb{P} of Ω that is same as 1. In that case, one can conclude X_n converges to 1 almost surely.

Because for all ω belonging to Ω the limit n tends to infinity X_n of ω is equal to 1. Therefore, finding the probability of ω belong into make a satisfying this condition that is X_n of ω tends to 1 as n tends to infinity, that is going to be the whole possible outcomes that is nothing but the \mathbb{P} of Ω that is equal to 1. Therefore, it satisfies the condition for almost surely. Therefore, X_n converges to 1, almost surely. So, the same example can be considered for other mode of convergence also.

(Refer Slide Time: 11:54)

$\therefore X_n \rightarrow 1$

$$\lim_{n \rightarrow \infty} P\{|X_n - 1| > \epsilon\} = 0$$

$\therefore X_n \xrightarrow{P} 1$

$$\lim_{n \rightarrow \infty} F_n(x) = F(x)$$

where $F(x) = \begin{cases} 0, & x < 1 \\ 1, & x \geq 1 \end{cases}$

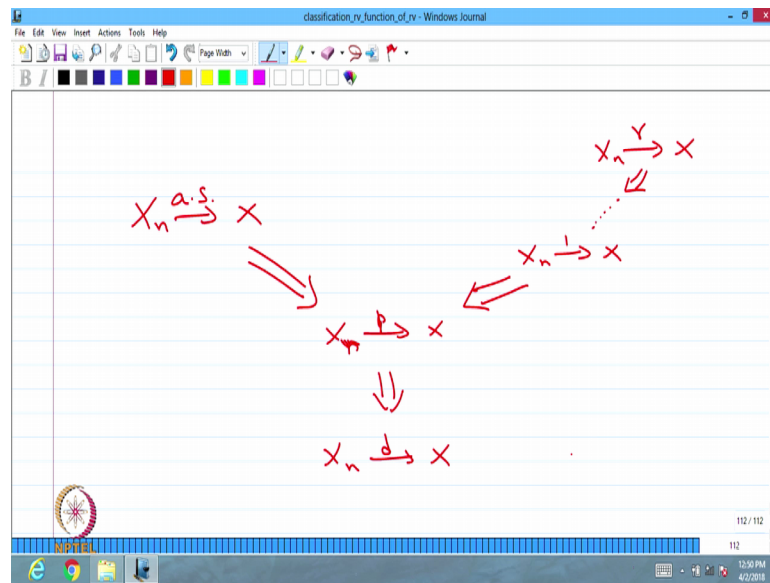

$\therefore X_n \xrightarrow{d} 1$

That means, one can prove limit n tends to infinity. The probability of absolute of X_n minus 1 greater than epsilon, that also we can prove this is going to be 0. This implies X_n converges to 1 in probability.

Similarly, for the same example, one can prove the sequence of random variable CDF's has a limit n tends to infinity will converges to F of X , where F of X is where F of X is takes a value 0 till 1 and 1 onwards, it is going to be 1. Therefore, we can conclude the same example X_n converges to 1 in distribution.

That means, there are few a sequence of random variable may converge to more than 1 mode of convergence. So, that can be connected in 1 nice way that is suppose you have a sequence of random variable and the random variable X defined on the probability space ω F P convergence in distribution and we have a convergence in probability.

(Refer Slide Time: 20:30)

Suppose, some sequence of random variable convergence in probability this implies convergence in distribution. The converse is not true it may be true for some few problems, in generalities not true.

Therefore, I am not writing the up adder converges not true in general. Similarly, if you have a X_n converges to X in the first order moment, this implies the converges in probability; Converse is also not true in general here. Suppose, you have a convergence in r th moment that implies the r minus 1 and so on till the first order moment.

But here, again converse is not true because of 2 reasons. The first order moment exist that does not being that the second order moment is going to exist; even if it exist it does not imply the convergence takes place. Therefore, the converse is not true. Convergence in a r th moment exist, then you can go for tilde first order moment convergence that implies the convergence in probability that implies convergence in distribution.

Now, I am giving the connection with the convergence in almost surely that is X_n converges to X almost surely. This implies convergence in probability, you see the different direction. Almost surely convergence implies convergence in probability convergence in probability implies convergence in distribution; no where converse is true in general.

There are some additional condition we can mention for some sequence of random variable, then we can conclude the X_n converges in X in probability that convergence in almost surely also. But for that you have to make a some additional condition. In general, the converse is not true for all the cases.

So, with this relation I am going to stop the convergence or modes of convergence. In the next class we will discuss about the law of large numbers.
