Now, I am going to give few State Transition Diagrams for the time homogeneous continuous time Markov chain. You see the first example it has only 2 states 0 and 1. So, the state space  $S$  is a 0 comma 1, and the time spend in the state 0 before moving into the state 1 that is, exponentially distributed with the parameter lambda. Once the system come to the state 1 in the time spend in the state 1 before moving into the state 0 that is exponentially distributed with the parameter mu, lambda is strictly greater than 0 and the mu is also strictly greater than 0.

That means; you know the exponential distribution has the mean 1 divided by the parameter therefore, the average time spent in the state 0, before moving into the state 1 that is, 1 divided by lambda. The average time spending in the state 1 before moving into the state 0 that is, 1 divided by mu. Since, it is a 2 state so over the time the system will be in the state 0 or 1, and you can classify the states also the way we have discussed in the continue discrete time Markov chain.

Since both the states are communicating, both the states are accessible from each other each other direction therefore; both the states are communicating each other. Since the state space is a 0 and 1 and both the states are communicating each other therefore, this is a irreducible Markov chain. For a irreducible Markov chain all the states are of the same type for a finite Markov chain we have at least one positive recurrent state therefore, both the states are going to be a positive recurrent state.

But here there is no periodicity for the continuous time Markov chain therefore, we can conclude the first example, both the states are positive recurrent and the Markov chain is a irreducible Markov chain. So, the continuous amount of time system spending in state 0 and 1 that is exponentially distributed with the parameters which I discussed earlier. Now I am moving into the second example. In the second example we have a state space is a countably infinite, and the system spending in this state 0 before moving into the state 1 that is, exponentially distributed with the parameter lambda naught.

Whereas in the state 1, the system can spend a exponential amount of time, the amount of time spending in the state 1 before moving into the state 2 that is exponentially distributed with the parameter lambda 1. And similarly the system spending in the state 1 before moving into the state 0 that is, exponentially distributed with the parameter mu 1 therefore, this is mu 1 and this is lambda 1.

(Refer Slide Time: 03:36)

Therefore, the time spending in the state 1 before moving into any other state that is, going to be minimum of the exponentially distributed with the parameter  $\lambda_1$ , 1 random variable you can call it as a  $X$  and you can call it as an other random variable that is, a exponentially distributed with the parameter  $\mu_1$  therefore, the amount of time spending in the state 1 before moving into any other state, that just now we have controlled at that waiting time distribution is exponentially distributed that we will come from here also.

So, here these 2 random variables are independent  $X$  and  $Y$  are independent random variables, both the random variables are independent therefore, the time spending in the state 1 before moving into any other state that is going to be minimum of the random variable with the exponential distributed parameter  $\lambda_1$  and the random variable which follows a exponential distribution with the parameter  $\mu_1$ . You know that the minimum of 2 exponential as long as both the random variables are independent random variable, then this is also going to be exponential distribution with the parameters, with the parameter  $\lambda_1 + \mu_1$ .

as long as both the random variables are independent and both are exponential. You can do it as a homework minimum of 2 exponential are going to be exponential with the parameter  $\lambda_1 + \mu_1$  therefore, the time spending in the state 1, that is exponential distribution with the parameter  $\lambda_1 + \mu_1$ . Also one can discuss what is the probability that the system moving into the state 2, before moving into the state 1, that is a  $\lambda_1$  divided by  $\lambda_1 + \mu_1$ .

Similarly, what is the probability that the system moving into the state 0 before moving into the state 2 that is  $\mu_1$  divided by  $\lambda_1 + \mu_1$ , that also you one can find out. So, what is the conclusion here is their time spending in the state 1 that is, exponential distribution with the parameter  $\lambda_1 + \mu_1$ . Similarly, the time spending in the state 2 that is suppose if it is a  $\lambda_2$  then  $\lambda_2 + \mu_2$ .

So, this is a one type of a continuous time Markov chain. The third example, this is also continuous time a Markov chain; in sort of a 2 dimensional Markov chain with the labeling with the 0 comma 0 1 comma 0 2 comma 0 and so on. So, all the labeling, which is parameters for the exponential distribution. So, the change from the discrete time Markov chain state transition diagram and the state transition diagram of a

continuous time Markov chain, here there is no cell flow. And the labels are the parameters for exponential distribution.

Whereas the discrete time Markov chain it is a one step transition probability going from one state to other states. Here the labels the arrow gives the, the time spending in the state exponential distribution with the parameter lambda naught and moving into the state 1 and so on.

Chapman-Kolmogorov Equation

$$\begin{aligned}
 P_{ij}(t+T) &= P_{\text{rob}}[X(t+T)=j / X(0)=i] \\
 &= \sum_{k \in S} P[X(t+T)=j, X(t)=k / X(0)=i] \\
 &= \sum_{k \in S} P[X(t+T)=j / X(t)=k, X(0)=i] \\
 &\quad \times P[X(t)=k / X(0)=i] \\
 P_{ij}(t+T) &= \sum_{k \in S} P_{kj}(T) P_{ik}(t) \quad \forall i, j \\
 &\quad t \geq 0, T \geq 0
 \end{aligned}$$

Now, I am going to find out how now I am going to find out the  $P_{ij}$  of  $t$  for that;  $i$  am going to do the derivation starting with the Chapman Kolmogorov equation.

Let me start with what is the transition probability of system is moving from  $i$  to  $j$  during the time  $0$  to  $t$  plus capital  $T$  that is nothing but, what is a transition probability system will be in the state  $j$  at the time point at  $t$  plus capital  $T$ , given that it was in the state  $i$  at time  $0$ . That is same as I can in between make a some other state, I can make a one more state  $k$  at time point  $t$ , for all possible values of  $k$  also  $i$  will get the same result.

That is same as I can make a summation over  $k$ ,  $k$  belonging to  $s$ ,  $s$  is a state space that is same as what is the conditional probability of system will be in the state  $j$  at the time point  $t$  plus capital  $T$  given that; it was in the state  $i$  at time  $0$  as well as it was in the state  $k$  at small  $t$  also, multiplied by what is the transition probability of system moving from  $0$  to  $t$  from the state  $i$  to  $k$ ; that is, same as the first conditional probability, you see this is

same as the Markov property which we have discussed in the definition of a continuous time Markov chain there I have discussed the CDF Cumulative Distribution Function.

Here it is the probability mass function whereas, this is a conditional probability mass function, what is the conditional probability mass function of system will be in the state  $j$  at time point a small  $t$  plus capital  $T$ , given that; it was in the state  $i$  at the time point  $0$  as well as it was in the state  $k$  at the time point  $t$ , and you know that  $0 < t < t + \text{capital } T$ , because the way we made it is all these values are greater than  $0$ .

Therefore, by using the Markov property of a continuous time Markov chain; so this is same as what is the probability that the system was in the state  $k$  at time small  $t$ . And move into the state  $j$  at the time point  $t$  plus capital  $T$ . Again you use the time homogeneous property, first we use the Markov property therefore, this is a transition probability of a  $t$  to  $t + t$  moving from the state  $k$  to  $j$ , then use the time homogeneous property therefore, only the length matters therefore,  $t$  to  $t$  plus capital  $T$  that is same as  $0$  to capital  $T$ .

Therefore, the system is moving from the state  $k$  to  $j$ , from  $0$  to capital  $T$  that is, a  $P_{kj}$  of  $T$ . The second one it is a transition probability system is moving from state  $i$  to  $k$  during the interval  $0$  to capital  $T$ . Therefore, this is a  $P_{ik}$  of  $t$  so this is valid for all  $i, j$  with the  $t$  greater than or equal to  $0$  and capital  $T$  is also greater than or equal to  $0$  therefore, the left hand side is the transition probability of system is moving from the state  $i$  to  $j$  from  $0$  to  $t$  plus capital  $T$  that is, same as the summation over  $I$  can rewrite in a different way;  $i$  to  $k$  in the interval  $0$  to small  $t$ ,  $k$  to  $j$  instead of a small  $t$  to small  $t$  plus capital  $T$  because of the time homogeneous I am just making  $0$  to capital  $T$ .

Therefore this is valid for all values of  $k$  summation, this equation is called the Chapman Kolmogorov equation for a time homogeneous continuous time Markov chain, because here for this transition probability we have used a Markov property as well as the time homogeneous property also therefore, this is a Chapman Kolmogorov equation of the transition probability of system moving from  $i$  to  $j$  in small  $t$  plus capital  $T$  can be broken into product of these for all possible values of  $k$ .

So, like this you can break it many more ways with the summation for all for different state of  $k$ . Using these we are going to find out the transition probability of  $P_{ij}$  of  $t$  you remember to find out the distribution of  $x$  of  $t$  you need a initial state probability vector

as well as the transition probability  $P_{ij}$  of  $t$ . The initial state probability vector is always given, you have to find out the  $P_{ij}$  of  $t$ ; once you know the  $P_{ij}$  of  $t$  you can find out the distribution of  $x$  of  $t$  for any time  $t$ .
