Lecture - 15
Statistical Inference

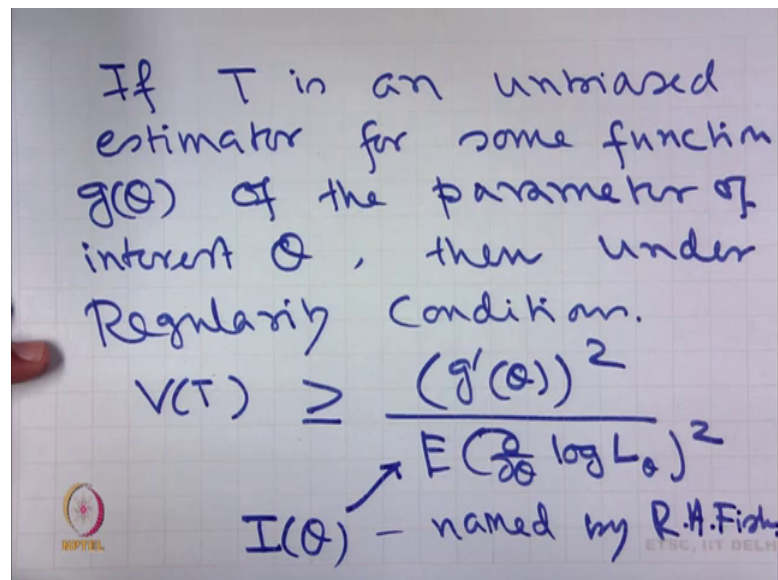

Welcome students to the MOOCS lecture on Statistical Inference. This is lecture number 15.

(Refer Slide Time: 00:37)

If you recollect in the last lecture we talked about 3 properties namely; unbiasedness, consistency, and efficiency. We are talking about minimum variance unbiased estimate and we have introduced the Cramer-Rao lower bound. What is that?

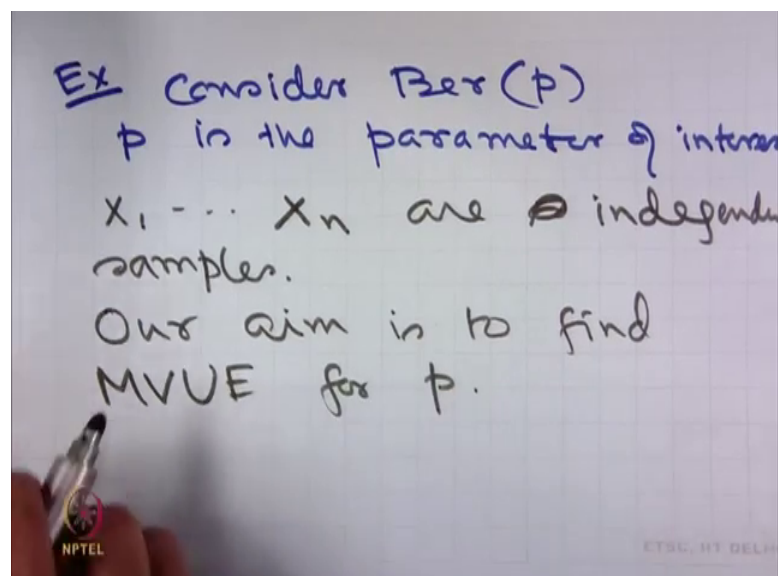

(Refer Slide Time: 01:55)

If T is an unbiased estimator for some function g of θ of the parameter of interest θ , then under regularity conditions variance of T is greater than equal to $g'(\theta)^2$ whole square divided by expected value of $\left(\frac{d}{d\theta} \log L_\theta\right)^2$ which depends on θ whole square and this quantity is called $I(\theta)$ named by R.A. Fisher.

Today first I will solve a few problems on efficiency or on minimum variance unbiased estimator, then I will introduce another important property of an estimator namely sufficiency. So, some example First.

(Refer Slide Time: 04:01)

Consider Bernoulli p . So, p is the parameter of interest. Suppose I have taken sample x_1, x_2, \dots, x_n are samples, independent samples, then our aim is to find the minimum variance unbiased estimator for p .

(Refer Slide Time: 05:19)

Observe that if $X \sim \text{Ber}(p)$
then $X = \begin{cases} 1 & \text{with prob } p \\ 0 & \text{with prob } 1-p \end{cases}$
 \therefore we can write the pmf
as $P(x) = p^x (1-p)^{1-x}$
 $\therefore L_p(x_1, \dots, x_n) = \prod_{i=1}^n p^{x_i} (1-p)^{1-x_i}$
 $= p^{\sum x_i} (1-p)^{n - \sum x_i}$

So, what we do is observe that if x follows Bernoulli p , then x takes two values; one with probability p and 0 with probability 1 minus p . Therefore, we can write the pdf or the pmf as p of x is equal to p to the power x 1 minus p whole to the power 1 minus x . So, check that if x is equal to 1 , then this is p to the power 1 into 1 minus p to the power 0 . Therefore, this is p and if x is equal to 0 , then this becomes 1 and this gives you 1 minus p to the power 1 that is 1 minus p .

Therefore, L_p of x_1, x_2, \dots, x_n that is the likelihood function of the sample x_1, x_2, \dots, x_n . When the parameter is p is equal to product of i is equal to 1 to n $p^{x_i} 1$ minus p to the power 1 minus x_i is equal to p to the power $\sum x_i$ into 1 minus p to the power n minus $\sum x_i$.

I hope this is clear to you because p to the power x_i i is equal to 1 to n . Therefore, the power gets added and here it is 1 minus p to the power 1 minus x_i . So, when I am adding this over n of the observations, I get n minus $\sum x_i$.

(Refer Slide Time: 07:59)

Handwritten mathematical derivations on a grid background:

$$\therefore \log L = \sum x_i \log p + (n - \sum x_i) \log(1-p)$$

$$\therefore \frac{\partial \log L}{\partial p} = \frac{\sum x_i}{p} + \frac{n - \sum x_i}{1-p} (-1)$$

$$= \frac{\sum x_i}{p} - \frac{n - \sum x_i}{1-p}$$

$$\therefore \frac{\partial^2 \log L}{\partial p^2} = \left[-\frac{\sum x_i}{p^2} - \frac{(n - \sum x_i)}{(1-p)^2} \right]$$

$$\therefore I(p) = E \left(\frac{\sum x_i}{p^2} + \frac{n - \sum x_i}{(1-p)^2} \right)$$

NPTEL logo is visible in the bottom left corner of the slide.

Therefore, log of L is equal to sigma x i log p plus n minus sigma x i into log of 1 minus p. Therefore, del log L del p. Remember that here theta is equal to p. The parameter that we are interested in is equal to sigma x i d log p dp is equal to 1 upon p plus n minus sigma x i upon 1 minus p into d 1 minus p dp which gives you minus 1 is equal to sigma x i upon p minus n minus sigma x i 1 minus p.

Therefore, del 2 log l del p square is equal to minus sigma x i upon p square minus n minus sigma x i upon 1 minus p whole square because this is 1 minus p to the power minus 1. Therefore, for that we get 1 minus 1 and it is 1 minus p. So, here like here like in this place here will be another minus 1. So, altogether there are 3 minuses which will keep it as minus and this is the del log L del p square.

Therefore, L p is equal to minus of that is equal to sigma x i upon p square plus n minus sigma x i upon 1 minus p whole square and we take expected value of that one. So, this is equal to we know that.

(Refer Slide Time: 10:56)

If $X \sim \text{Ber}(p)$
 X_1, \dots, X_n are independent samples
then $\sum X_i \sim \text{Bin}(n, p)$.
 $\therefore E(\sum X_i) = np$.
 $\therefore I(p) = \frac{np}{p^2} + \frac{n-np}{(1-p)^2}$
 $= \frac{n}{p} + \frac{n}{1-p} = \frac{n}{p(1-p)}$

If X follows Bernoulli and x_1, x_2, \dots, x_n are samples, then $\sum x_i$ there is a binomial with np . Therefore, expected value of $\sum x_i$ is equal to np . Therefore, using the linearity we can write $I(p)$ is equal to $\frac{np}{p^2}$ plus $\frac{n-np}{(1-p)^2}$ is equal to $\frac{n}{p}$ plus $\frac{n}{1-p}$ is equal to $\frac{n}{p(1-p)}$. Therefore, this is my information about p that I get from the sample.

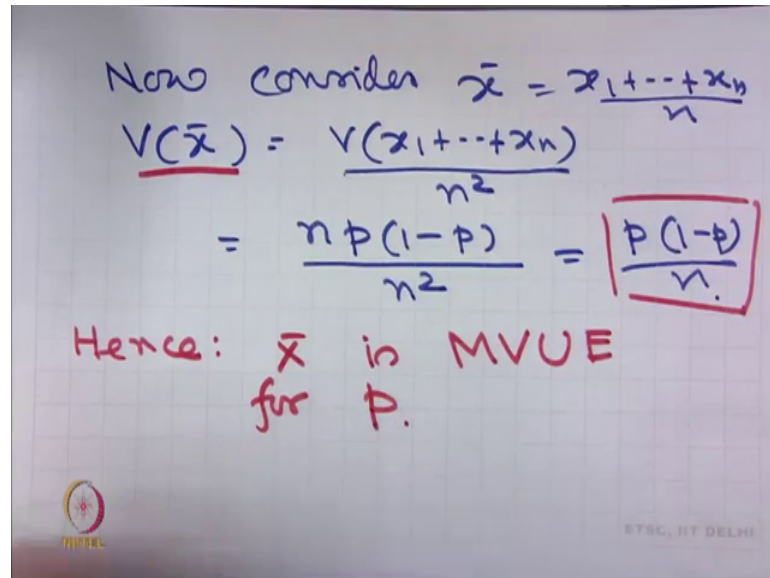

(Refer Slide Time: 12:49)

\therefore Cramer - Rao Lower bound for an unbiased estimator of p is $\frac{1}{\frac{n}{p(1-p)}} = \frac{p(1-p)}{n}$
Here $g(p) = p$
 \therefore We get 1 in the numerator.

Therefore by Cramers-Rao Inequality or Cramer-Rao lower bound for an unbiased estimator of p is $\frac{1}{n p (1-p)}$ is equal to $\frac{p(1-p)}{n}$. Note

that this one comes because in the numerator we are writing g prime p square. Here g p is equal to p . Therefore we get in the numerator 1. So, this is the lower bound for an unbiased estimator.

(Refer Slide Time: 14:15)

Now consider $\bar{x} = \frac{x_1 + \dots + x_n}{n}$

$$V(\bar{x}) = \frac{V(x_1 + \dots + x_n)}{n^2}$$

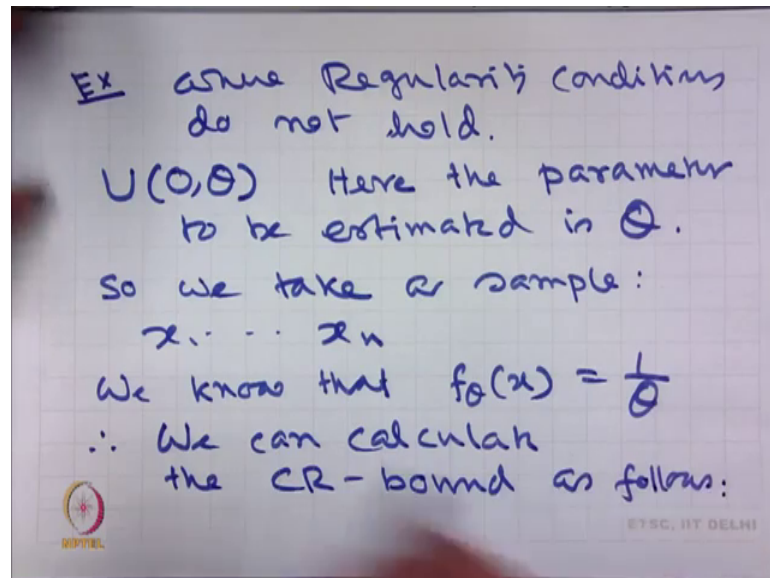

$$= \frac{np(1-p)}{n^2} = \boxed{\frac{p(1-p)}{n}}$$

Hence: \bar{x} is MVUE for p .

Now, let us consider \bar{X} is equal to x_1 plus x_2 plus x_n by n . Now, variance of \bar{X} is equal to variance of x_1 plus x_2 plus x_n divided by n square is equal to n into p into 1 minus p . This we know because x_1 plus x_2 up to x_n is a binomial distribution. Therefore, it has variance n p into 1 minus p divided by a square is equal to p into 1 minus p upon n .

Therefore, what we find that variance of \bar{X} is equal to p into 1 minus p upon n which is the Cramer-Rao bound as we have already seen here. Hence, \bar{X} is minimum variance unbiased estimator for p .

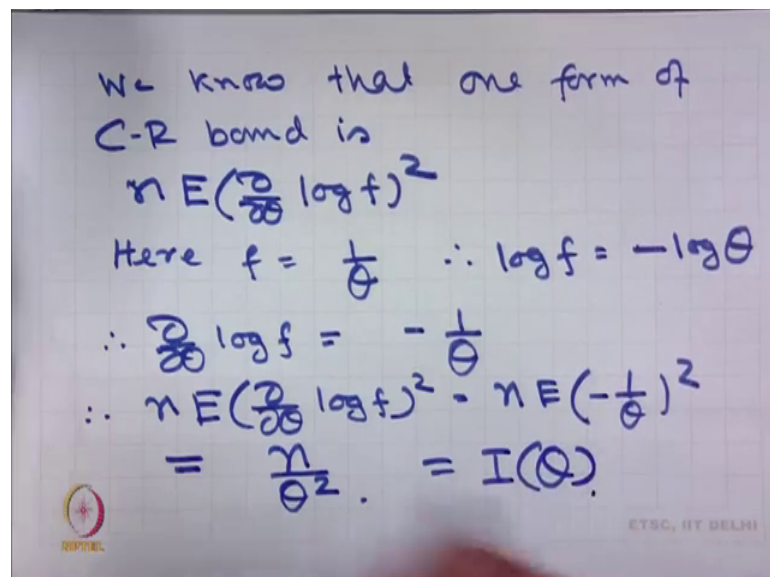

(Refer Slide Time: 15:46)

Let us now consider an example where regularity conditions do not hold. So, for example, consider uniform 0 theta. Here the parameter to be estimated is theta.

So, we take a sample x_1, x_2, \dots, x_n and we know that $f_\theta(x)$ is equal to $1/\theta$ upon theta as it is uniform in the interval 0 theta. Therefore, we can calculate the Cramer-Rao bound as follows.

(Refer Slide Time: 17:23)

We know that one form of Cramer-Rao bound is n times expected value of $\frac{d}{d\theta} \log f$ square. Here f is equal to $1/\theta$ by θ . Therefore, $\log f$ is equal to $-\log \theta$. Therefore, $\frac{d}{d\theta} \log f$ is equal to $-1/\theta$.

Therefore, n expected value of $\frac{d}{d\theta} \log f$ square is equal to n into expected value of $1/\theta^2$ is equal to n upon θ^2 . So, this is equal to $1/\theta^2$.

(Refer Slide Time: 18:53)

\therefore The CR - lower bound
 of an unbiased estimator
 is $\frac{1}{n \frac{d^2}{d\theta^2}}$ $\leftarrow g(\theta) = \theta$
 $\therefore (g'(\theta))^2 = 1$
 $= \frac{\theta^2}{n}$
 An unbiased estimator of θ
 the variance should be \geq
 $\frac{\theta^2}{n}$.

The Cramer-Rao lower bound of an unbiased estimator is $1/n$ by θ^2 . This one is coming because $g(\theta)$ is equal to θ . Therefore, $(g'(\theta))^2$ is equal to 1 is equal to θ^2/n . Therefore, for all unbiased estimator of θ , the variance should be greater than or equal to θ^2/n .

(Refer Slide Time: 20:07)

Let us consider an unbiased estimator for θ .

We know $E(X_{(n)}) = \frac{n}{n+1} \theta$

\uparrow
nth order statistic

$\therefore \frac{n+1}{n} X_{(n)}$ is an unbiased estimator for θ .

 NPTEL

ETSC, IIT DELHI

Let us consider an unbiased estimator for θ . We know expected value of x_n the n th order statistic is equal to $n \text{ upon } n + 1 \theta$. Therefore, $n + 1 \text{ upon } n x_n$ is an unbiased estimator for θ .

(Refer Slide Time: 21:15)

Let us compute the variance of $\frac{n+1}{n} X_{(n)}$.

$$\begin{aligned} V\left(\frac{n+1}{n} X_{(n)}\right) &= \left(\frac{n+1}{n}\right)^2 \left(E(X_{(n)}^2) - (E(X_{(n)}))^2 \right) \\ &= \left(\frac{n+1}{n}\right)^2 E(X_{(n)}^2) - \left(\frac{n+1}{n}\right)^2 \left(\frac{n}{n+1}\theta\right)^2 \\ &= \left(\frac{n+1}{n}\right)^2 E(X_{(n)}^2) - \theta^2. \end{aligned}$$

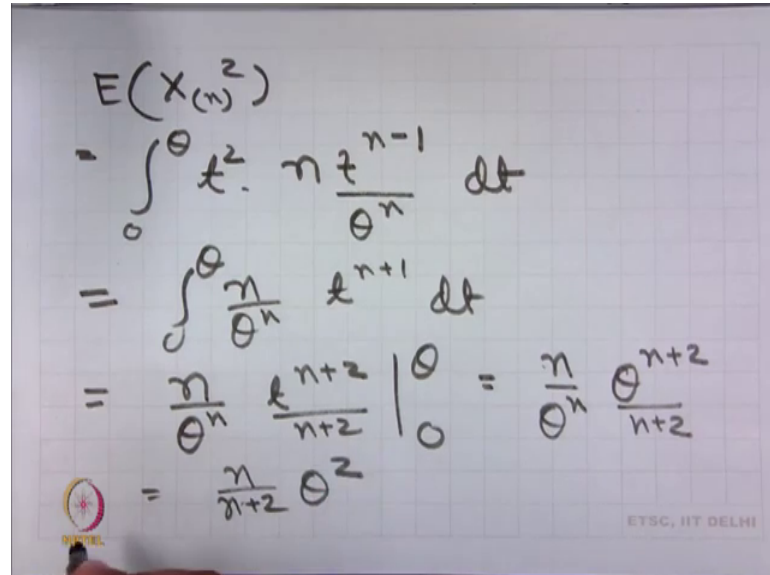

NPTEL ETSC, IIT DELHI

Let us compute the variance of n plus 1 upon $n \times n$ variance of n plus 1 upon $n \times n$ is equal to n plus 1 upon n whole square into expected value of x n square minus expected value of x n whole square is equal to n plus 1 upon n whole square into expected value of

x n square minus n plus 1 upon n whole square into n upon n plus 1 theta whole square is equal to n plus 1 upon n whole square expected value of x n square minus theta square.

So, let us compute expected value of x n square.

(Refer Slide Time: 22:48)

$$\begin{aligned}
 E(X_n^2) &= \int_0^\theta t^2 \cdot \frac{n t^{n-1}}{\theta^n} dt \\
 &= \int_0^\theta \frac{n}{\theta^n} t^{n+1} dt \\
 &= \frac{n}{\theta^n} \left[\frac{t^{n+2}}{n+2} \right]_0^\theta = \frac{n}{\theta^n} \frac{\theta^{n+2}}{n+2} \\
 &= \frac{n}{n+2} \theta^2
 \end{aligned}$$

ETSC, IIT DELHI

This is equal to integration 0 to theta. Let the value be t . We know that the pdf of x n is equal to t square and we know that the pdf of x n is equal to $n t$ to the power n minus 1 upon theta to the power n . And therefore, we are integrating it with respected to t . This is equal to 0 to theta n upon theta to the power n t to the power n plus 1, dt is equal to n theta power n t to the power n plus 2 upon n plus 2 theta, 0 is equal to n theta power n theta to the power n plus 2 upon n plus 2 is equal to n upon n plus 2 theta square.

(Refer Slide Time: 24:35)

$$\begin{aligned}
 & \therefore V\left(\frac{n+1}{n} x_{(n)}\right) \\
 &= \left(\frac{n+1}{n}\right)^2 \cdot \frac{n}{n+2} \theta^2 - \theta^2 \\
 &= \frac{(n+1)^2}{n(n+2)} \theta^2 - \theta^2 \\
 &= \theta^2 \left(\frac{n^2 + 2n + 1}{n(n+2)} - 1 \right) \\
 &= \frac{1}{n(n+2)} \theta^2 \therefore \left(\frac{\theta^2}{n(n+2)} \right) \not\geq \frac{\theta^2}{n}
 \end{aligned}$$

Therefore, variance of $n+1$ upon $n \times n$ is equal to $n+1$ upon n whole square into n upon $n+2$ theta square minus theta square is equal to $n+1$ whole square upon n into $n+2$ theta square minus theta square is equal to theta square into a square plus $2n+1$ n into $n+2$ minus 1 is equal to 1 upon n into $n+2$ theta square. And we have already found that the Cramer-Rao bound we have already found that the Cramer-Rao bound is theta square by n .

Therefore, theta square upon n into $n+2$ has to be greater than equal to theta square by n which is not correct for any positive n , because n is the number of samples and if n is equal to an integer $1\ 2\ 3$. Therefore this is never valid or in other words, we have found an unbiased estimator whose variance does not obey that Cramer-Rao lower bound.

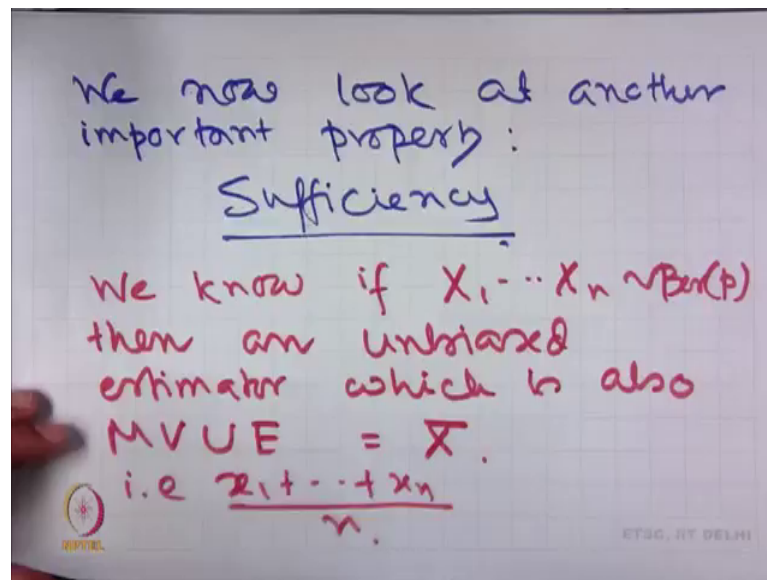

(Refer Slide Time: 26:49)

That question is why did it happen? It happens because the range of integration while computing the variance is 0 to theta dt that what we have done and this limit of integration is not independent of theta. Hence, the regularity condition does not hold and therefore, the Cramer-Rao lower bound is no more acting as a lower bound for the variance of an unbiased estimator in this case.

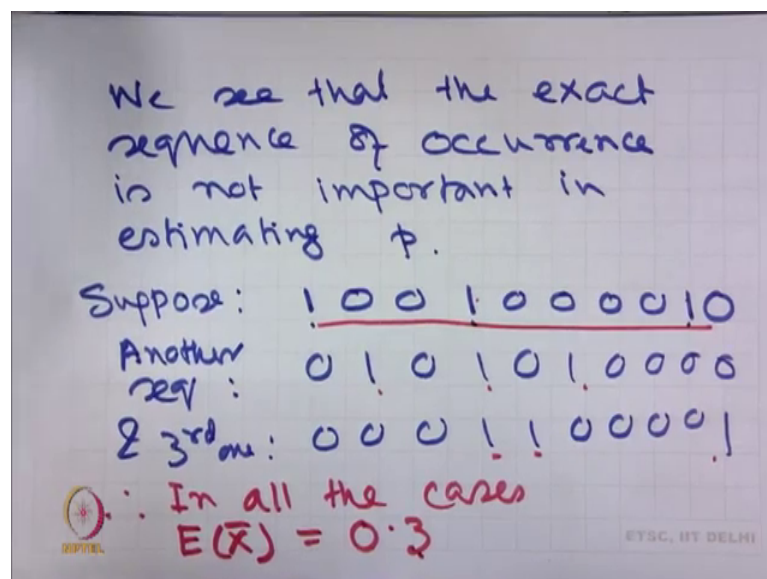

So, that is the importance of the regularity conditions because without them the minimum variance unbiased estimator bound will not be valid with that I close the chapter on efficiency.

(Refer Slide Time: 28:07)

We now look at another important property, namely sufficiency. The concept is as follows. We know that if X_1, X_2, \dots, X_n are from Bernoulli p , then an unbiased estimator which is also MVUE is equal to \bar{X} that is x_1 plus x_2 plus x_n by n .

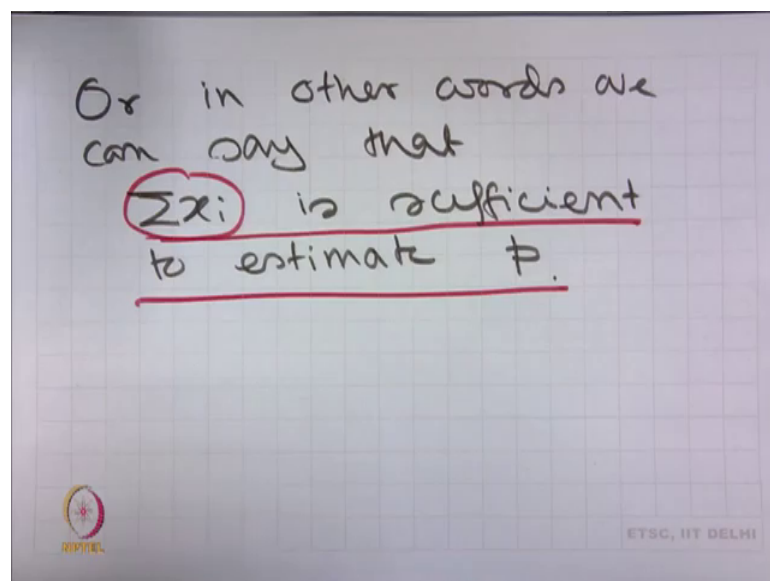

(Refer Slide Time: 29:30)

Therefore, if we observe we see that the exact sequence of occurrence is not important in estimating p . Suppose I toss the coin 10 times and my observations are 1 0 0 1 0 0 0 0 1 0, that means out of 10 tosses I have got 3 heads and rest are tails. Suppose another sequence is 0 1 0 1 0 1 0 0 0 0 and the third one is 0 0 0 1 1 0 0 0 0 1. In all the 3 cases,

we find that out of 10 tosses there are 3 heads and therefore, in all the cases expected value or the estimate is \bar{X} , then expected value of \bar{X} is equal to 0.3 or in other words, we notice that this sample may contain a lot more information rather than just the summation of that one; namely what is the first result, what is the last result, how many times 0 and 1 occurred together etcetera. All this different informations one can find out from each sample, but while estimating the value of p , we do not really need any one of them. What I need is only the sum of the observations that is the number of heads that I found in the sample.

(Refer Slide Time: 32:35)

So, in other words we can say that $\sum x_i$ is sufficient to estimate p . We do not need any other information. If I get only $\sum x_i$, then that is good enough for us to estimate p . This is the basic idea of sufficiency.

(Refer Slide Time: 33:27)

Def An estimator $T(x_1, \dots, x_n)$ is said to be sufficient for θ if the conditional distribution of X_1, \dots, X_n given the value of T is independent of θ , where θ is the parameter of interest.

Mathematically the definition is that an estimator T of θ is said to be sufficient for θ if the conditional distribution of X_1, X_2, \dots, X_n given the value of T is independent of θ , where θ is the parameter of interest or in other words, if instead of θ we call it ϕ , we can say that if T is said to be sufficient for estimating θ if the conditional distribution of X_1, X_2, \dots, X_n given the value of T is independent of θ .

(Refer Slide Time: 35:36)

Consider again $\text{Bern}(\theta)$
 & we have x_1, \dots, x_n
 We know the pmf = $\theta^{x_i} (1-\theta)^{1-x_i}$
 $\forall i=1, \dots, n$
 $\therefore P(X_1=x_1, \dots, X_n=x_n)$
 $= \theta^{\sum x_i} (1-\theta)^{n-\sum x_i}$
 Now suppose the value of $\sum x_i = k$ (given).

So, let us look at for Bernoulli and we have x_1, x_2, \dots, x_n . We know the pdf or the pmf is equal to p to the power x_i minus p to the power $1 - x_i$ for all i is equal to 1 to n .

Therefore, $P(X_1 = x_1, \dots, X_n = x_n | T = k)$ is equal to $p^{\sum x_i} (1-p)^{n - \sum x_i}$.

(Refer Slide Time: 37:05)

The image shows a handwritten derivation on a grid background. At the top, it states: $\therefore P(X_1 = x_1, \dots, X_n = x_n | T = k)$. Below this, it shows the formula:
$$= \frac{P(X_1 = x_1, \dots, X_n = x_n \text{ and } T = k)}{P(T = k)}$$
 with an arrow pointing from $\sum x_i$ to $T = k$ in the numerator. A large bracket on the left side of the next line indicates a condition: "If x_1, \dots, x_n are such that $\sum x_i = k$ then". Below this, it shows the simplified formula:
$$= \frac{P(X_1 = x_1, \dots, X_n = x_n)}{P(T = k)}$$
 with an arrow pointing from $\sum x_i$ to $T = k$ in the denominator. In the bottom left corner, there is a small logo for "OPPORTUNITY". In the bottom right corner, it says "ETSC, IIT DELHI".

Now, suppose the value of $\sum x_i$ is equal to k given, therefore probability $X_1 = x_1, \dots, X_n = x_n$ given $T = k$. Where, $T = \sum x_i$ is equal to k . What is this quantity if x_1, x_2, \dots, x_n are such that $\sum x_i = k$. Then, the above is probability $X_1 = x_1, \dots, X_n = x_n$ being I do not need to consider this because that is going to be satisfied automatically divided by probability $T = k$. Where, $T = \sum x_i$ is equal to $p^{\sum x_i} (1-p)^{n - \sum x_i}$ and $\sum x_i$ is equal to k divided by probability $T = k$ that is probability $\sum x_i = k$.

(Refer Slide Time: 38:37)

$$\begin{aligned}
 &= \frac{p^{\sum x_i} (1-p)^{n-\sum x_i}}{P(\sum x_i = k)} \quad \text{if } \sum x_i = k \\
 &= \frac{p^k (1-p)^{n-k}}{\binom{n}{k} p^k (1-p)^{n-k}} = \frac{1}{\binom{n}{k}} \\
 &\text{If } x_1, \dots, x_n \text{ are such that } \sum x_i \neq k, \text{ then the numerator is 0.}
 \end{aligned}$$

So, this is nothing but p to the power k 1 minus p whole to the power n minus k divided by since $\sum x_i$ is now a binomial random variable with parameter n, p , it will take the value k with probability $\binom{n}{k} p^k (1-p)^{n-k}$ is equal to you see that these cancels with this. Therefore, we are left with 1 upon $\binom{n}{k}$ and if x_1, x_2, \dots, x_n are such that $\sum x_i$ is not equal to k , then the numerator is 0 .

(Refer Slide Time: 40:13)

$$\begin{aligned}
 &\therefore \text{The conditional distribution of } x_1, \dots, x_n \mid T = k \\
 &= \begin{cases} 0 & \text{if } \sum x_i \neq k \\ \frac{1}{\binom{n}{k}} & \text{if } \sum x_i = k \end{cases} \\
 &\text{independent of } p. \\
 &\therefore \sum x_i \text{ is a sufficient statistic to estimate } p.
 \end{aligned}$$

Therefore, the conditional distribution of x_1, x_2, \dots, x_n given $T = k$ is 0 if $\sum x_i$ is not equal to k or this is equal to 1 upon $\binom{n}{k}$ if $\sum x_i$ is equal to k .

Therefore, we see that this is independent of p . Therefore, $\sum x_i$ is sufficient to estimate p and these we have are good.

(Refer Slide Time: 41:27)

Ex Shows that
 $T = \frac{X_1 + 3X_2 + 2X_3}{6}$ is Not
sufficient for estimating p
when $X_1, X_2, X_3 \sim \text{Ber}(p)$
 $\therefore E(T) = p$
 $\frac{X_1 + 3X_2 + 2X_3}{6}$ is unbiased
for p .

ETSC, IIT DELHI

I have already shown that $X_1 + 3, X_2 + 2, X_3 + 6$ is not sufficient for estimating p when X_1, X_2, X_3 are from Bernoulli p .

So, we have a Bernoulli distribution. We have taken 3 observations from here and my statistic is $X_1 + 3, X_2 + 2, X_3 + 6$. Let us call it T . Therefore, expected value of T is equal to p because each X_i is an unbiased estimator for p . Therefore, $p + 3, p + 2, p + 6$ upon 6 is equal to p . Therefore, $X_1 + 3, X_2 + 2, X_3 + 6$ is unbiased for p .

(Refer Slide Time: 43:13)

Is it sufficient?
consider the case $T = \frac{1}{2}$
Case 1: If $X_1 = 1$ $X_2 = 0$ $X_3 = 1$
then $E\left(\frac{X_1 + 3X_2 + 2X_3}{6}\right) = \frac{1}{2}$
Case 2 if $X_1 = 0$ $X_2 = 1$ $X_3 = 0$
then also $\frac{X_1 + 3X_2 + 2X_3}{6} = \frac{1}{2}$

Question is, is it sufficient? We say that consider the case when T is equal to half. So, case 1 if X_1 is equal to 1 X_2 is equal to 0 and X_3 is equal to 1, then expected value of X_1 plus 3, X_2 plus 2, X_3 upon 6 is equal to half and case 2, if X_1 is equal to 0, X_2 is equal to 1 and X_3 is equal to 0, then also X_1 plus 3, X_2 plus 2, X_3 upon 6 is it is expected value or this is equal to half.

(Refer Slide Time: 44:50)

$\therefore P(T = \frac{1}{2}) =$
 $P(X_1 = 1, X_2 = 0, X_3 = 1)$
 $+ P(X_1 = 0, X_2 = 1, X_3 = 0)$
 $= p^2(1-p) + p(1-p)^2$
Post conditional probability
 $P(X_1 = 1, X_2 = 0, X_3 = 1 \mid T = \frac{1}{2})$
 $= \frac{p^2(1-p)}{p^2(1-p) + p(1-p)^2}$ NOT independent of p

Therefore, probability T is equal to half is equal to probability X_1 is equal to 1, X_2 is equal to 0 and X_3 is equal to 1 plus probability X_1 is equal to 0, X_2 is equal to 1, X_3 is equal to 0 is equal to $p^2 + (1-p)^2$.

So, that is the probability that the statistic T is going to take the value half, but a conditional probability X_1 is equal to 1, X_2 is equal to 0, X_3 is equal to 1 given T is equal to half is equal to $p^2 + (1-p)^2$ upon $p^2 + (1-p)^2$ plus $p + (1-p)$ and this is not independent of p . Therefore, we see that even if this is an unbiased estimator $X_1 + 3, X_2 + 2, X_3$ by 6, this is not sufficient to estimate the value of p , ok.

Friends with that I stop here. In the next class, I shall do some more studies of sufficiency.

Thank you.
