Lecture - 17
Statistical Inference

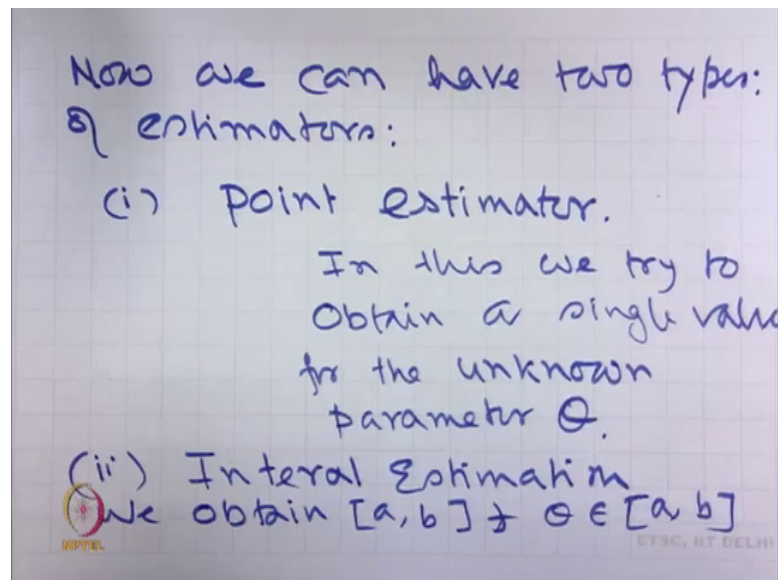

Welcome student to the MOOCs series of lecture on Statistical Inference. This is lecture number 17. Over the last few classes we have been discussing theory of estimation. In particular we have discussed desired properties of an estimator namely unbiasedness, consistency, efficiency, sufficiency which we expect in a good estimator to have.

(Refer Slide Time: 01:00)

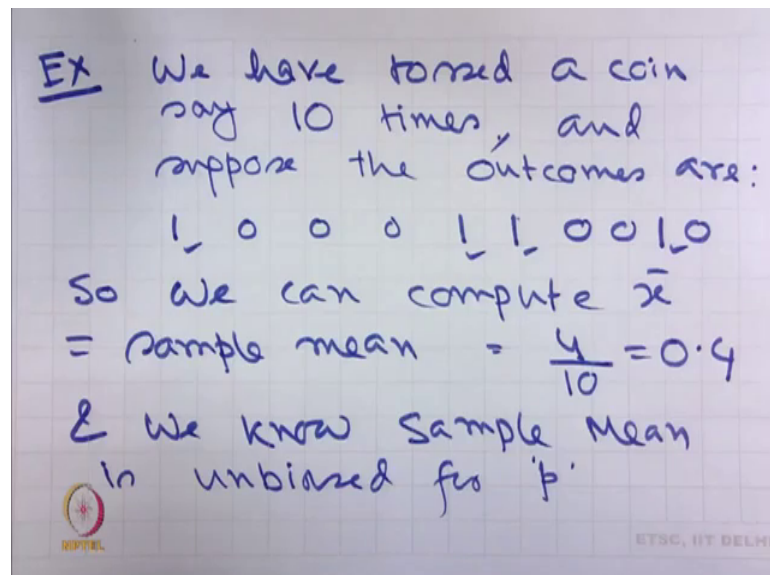

But the main question is how to find an estimator. Suppose we have X_1, X_2, \dots, X_n as samples from a distribution. If $f(x; \theta)$ or I may write $f_\theta(x)$, where θ is the parameter of the distribution. And we know that θ belongs to capital Θ the parameters space. For example, Bernoulli p , p belongs to $(0, 1)$.

(Refer Slide Time: 02:32)

Now we can have estimator of two types: one is point estimation or point estimator. In this case, we try to obtain a single value for the unknown parameter theta. And the second one is interval estimation where you try to obtain an interval such that theta belongs to this interval with certain degree of confidence.

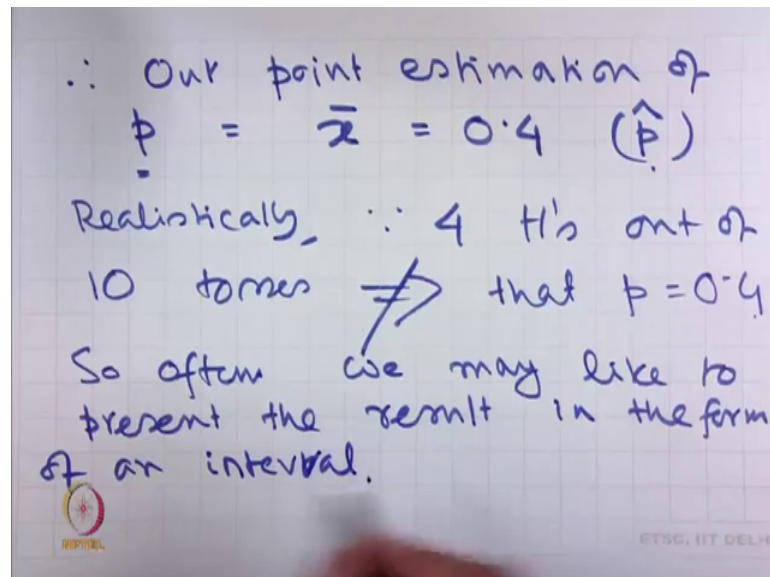

(Refer Slide Time: 04:16)

For example, we have tossed a coin say 10 times. And suppose the outcomes are head tail tail tail head head tail tail head and tail.

So, we can compute \bar{x} is equal to sample mean is equal to 4 divided by 10, 4 comes because there are 4 success is equal to 0.4. And we know that sample mean is an unbiased estimator. Sample mean is unbiased for p .

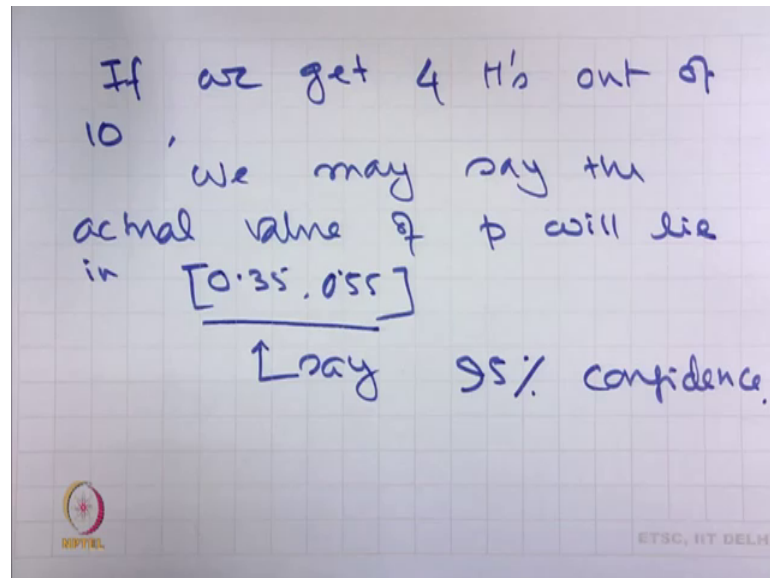

(Refer Slide Time: 06:02)

Therefore, our point estimation of p is equal to \bar{x} is equal to 0.4. And we often denote it as \hat{p} where \hat{p} is an estimated value of the unknown parameter p , but if we think realistically just because we got 4 heads out of 10 tosses does not imply that P is equal to 0.4.

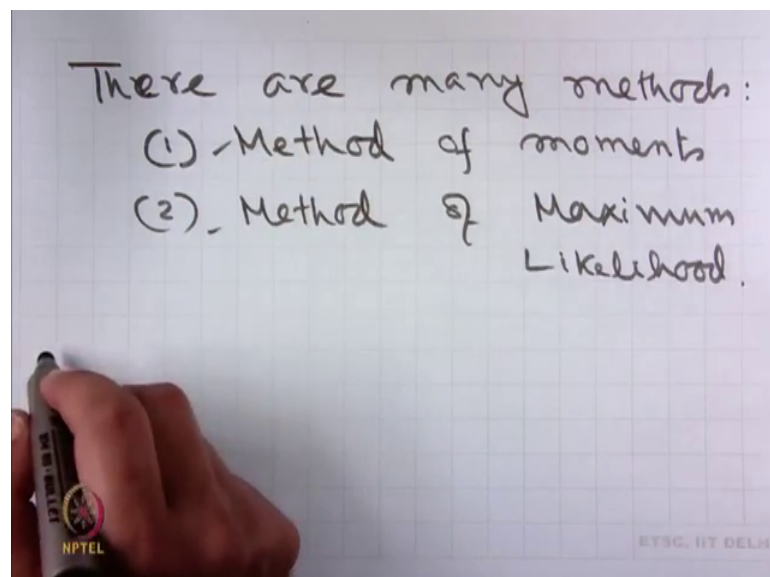

In another set of experiments, you may get with the same coin different values of \hat{p} . So, often we may like to present the result in the form of an interval.

(Refer Slide Time: 07:44)

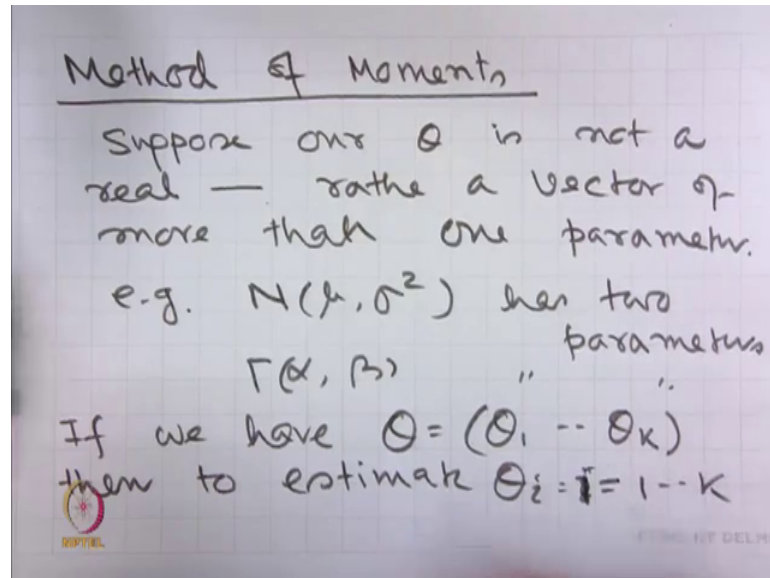

Say for example, if we get 4 heads out of 10. We may say the actual value of p will lie in say 0.35 to say 0.55. So, we are giving an interval and we are saying that the value of the parameter will lie in this interval with a certain degree of confidence, say 95 percent confidence. When you present the result in this manner, we call it an interval estimation of the parameter. In the present talk I will be discussing point estimation primarily.

(Refer Slide Time: 09:05)

There are many methods, but the two most important to answer method of moments and method of maximum likelihood. So, in this talk, I will be discussing these two methods in detail.

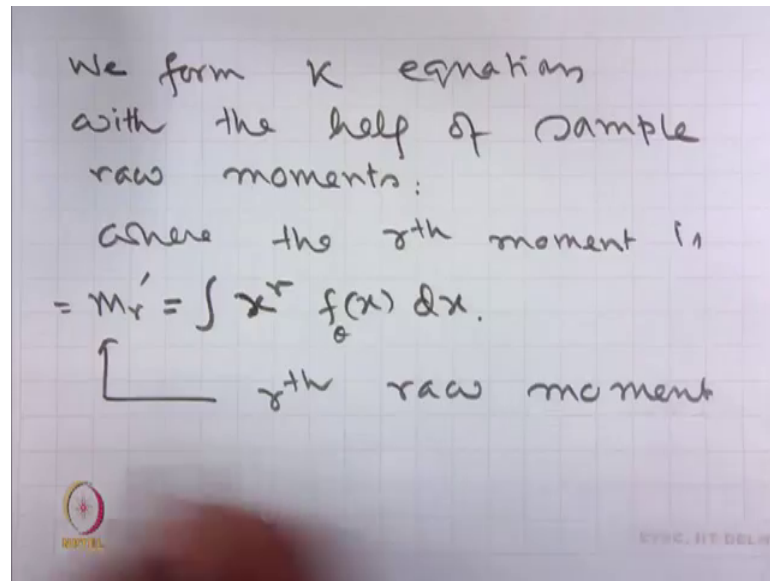

(Refer Slide Time: 09:56)

So, method of moments suppose our theta is not a real rather a vector of more than one parameter. For example, normal mu sigma square has two parameters. Similarly gamma alpha beta has two parameters.

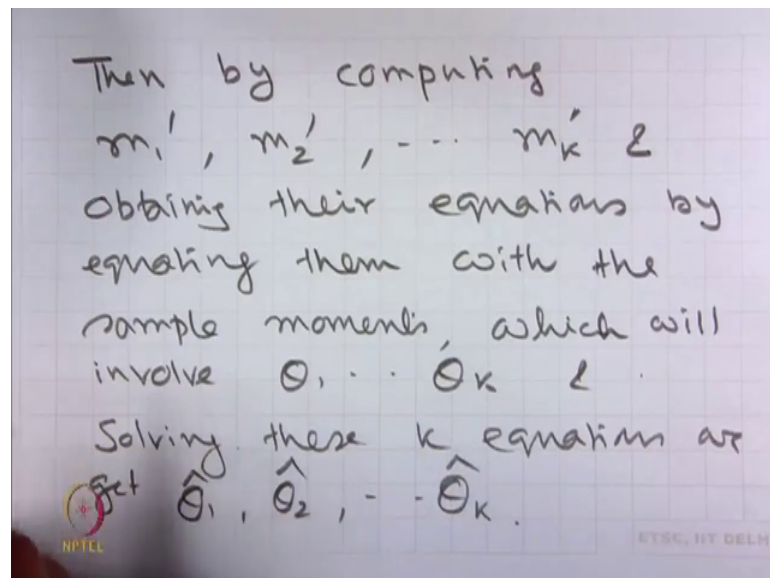

So, if we have theta is equal to a K dimensional vector theta1 theta 2 up to theta K, then to estimate theta versus theta i is equal to i is equal to 1 to K.

(Refer Slide Time: 11:40).

We form K equations with the help of sample raw moments where the r th moment is $\int x^r f(x) dx$. This is the r th raw moment.

(Refer Slide Time: 12:50)

Then by computing m_1' , m_2' up to m_k' and obtaining their equations by equating them with the sample moments, which will involve θ_1 , θ_2 up to θ_k . And solving this k equations, we get $\hat{\theta}_1$, $\hat{\theta}_2$ up to $\hat{\theta}_k$.

(Refer Slide Time: 14:22)

Ex: $\Gamma(\lambda, \alpha)$ We need to estimate λ & α .
we have taken n samples from the population.
The first moment = $\mu_1' = E(X) = \frac{\alpha}{\lambda}$
& the 2nd moment = $\mu_2' = E(X^2) = \int_0^{\infty} x^2 \frac{\lambda^\alpha}{\Gamma(\alpha)} e^{-\lambda x} x^{\alpha-1} dx$

So, let me give you an example: gamma lambda alpha. We need to estimate lambda and alpha. So, what we have done? We have taken say n samples from the population. Then what is the first moment? The first moment is equal to μ_1' and we know that for gamma it is expected value of X is equal to α upon λ . And the second moment is equal to μ_2' is equal to expected value of X square is equal to $\int_0^{\infty} x^2 \lambda^\alpha \text{ upon } \Gamma(\alpha) e^{-\lambda x} x^{\alpha-1} dx$ which is equal to $\int_0^{\infty} x^2 \lambda^\alpha \text{ upon } \Gamma(\alpha) e^{-\lambda x} x^{\alpha-1} dx$.

(Refer Slide Time: 16:13)

$$\begin{aligned} &= \int_0^{\infty} x^2 \frac{\lambda^\alpha}{\Gamma(\alpha)} e^{-\lambda x} x^{\alpha-1} dx \\ &= \int_0^{\infty} \frac{\lambda^\alpha}{\Gamma(\alpha)} e^{-\lambda x} x^{\alpha+2-1} dx \\ &= \frac{\lambda^\alpha}{\Gamma(\alpha)} \times \left(\frac{\Gamma(\alpha+2)}{\lambda^{\alpha+2}} \right) = \frac{\alpha(\alpha+1)\Gamma(\alpha)}{\lambda^2 \cdot \Gamma(\alpha)} \\ \therefore \text{After cancellation:} \\ \text{we have } \mu_2' &= \frac{\alpha(\alpha+1)}{\lambda^2} \end{aligned}$$

And we know that this is going to be lambda power alpha upon gamma alpha into gamma alpha upon lambda power alpha plus gamma alpha plus 2 upon lambda power alpha plus 2 which is equal to alpha into alpha plus 1 gamma alpha this part is equal to alpha into alpha plus 1 times gamma alpha into lambda square into lambda power alpha. Therefore, after cancellation we have mu 2 prime is equal to alpha into alpha plus 1 upon lambda square.

(Refer Slide Time: 18:00)

Suppose now from the sample we calculate:

$$\frac{\sum x_i}{n} \text{ \& call it } m_1'$$
$$\frac{\sum x_i^2}{n} \text{ \& call it } m_2'$$
$$\therefore m_1' = \frac{\alpha}{\lambda}$$
$$m_2' = \frac{\alpha(\alpha+1)}{\lambda^2}$$
$$\therefore \frac{m_2'}{m_1'^2} = \frac{\alpha(\alpha+1)}{\alpha^2}$$

Suppose now, from the sample we calculate $\sum X_i$ by n where n is the sample size and call it m_1 prime and $\sum X_i^2$ by n and call it m_2 prime. Then we can write m_1 prime is equal to α over λ and m_2 prime is equal to α into α plus 1 upon λ square. Therefore, m_2 prime upon m_1 prime square is equal to α into α plus 1 upon α square as this λ square will get cancelled.

(Refer Slide Time: 19:34)

$$\therefore \frac{m_2'}{m_1'^2} = \frac{\alpha + 1}{\alpha}$$

$$\therefore \alpha m_2' = (\alpha + 1) m_1'^2$$

$$\text{or } \alpha (m_2' - m_1'^2) = m_1'^2$$

$$\therefore \text{An estimate of } \alpha$$

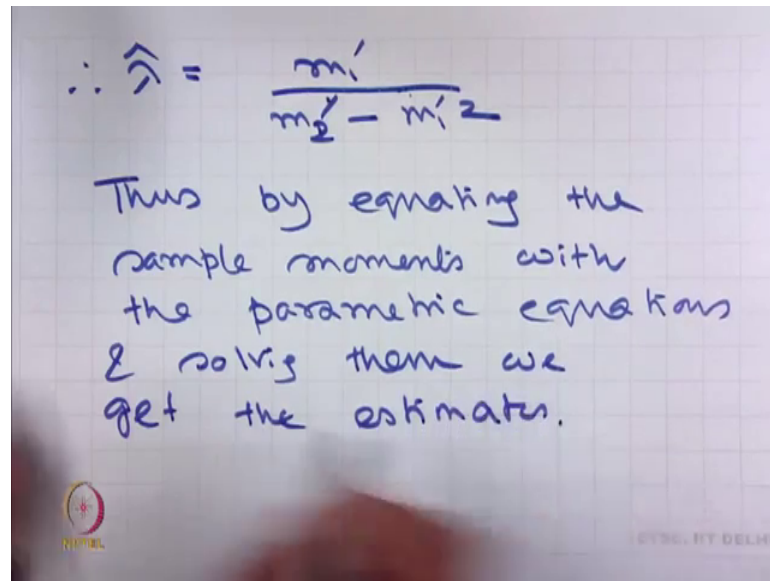

$$= \hat{\alpha} = \frac{m_1'^2}{m_2' - m_1'^2} \quad \checkmark$$

$$\therefore \text{Since } \frac{\alpha}{\lambda} = \frac{m_1'}{m_1} \quad \therefore \frac{\hat{\alpha}}{\hat{\lambda}} = \frac{m_1'}{m_1}$$

Therefore, m_2 prime upon m_1 prime square is equal to α plus 1 upon α . Therefore, αm_2 prime is equal to α plus 1 m_1 prime square or α times m_2 prime minus 1 prime square is equal to m_1 prime square. Therefore, an estimate of α is equal to α hat is equal to m_1 prime square upon m_2 prime minus m_1 prime square. Therefore, since we know that α upon λ is equal to m_1 prime; therefore, λ upon α is equal to 1 upon m_1 prime.

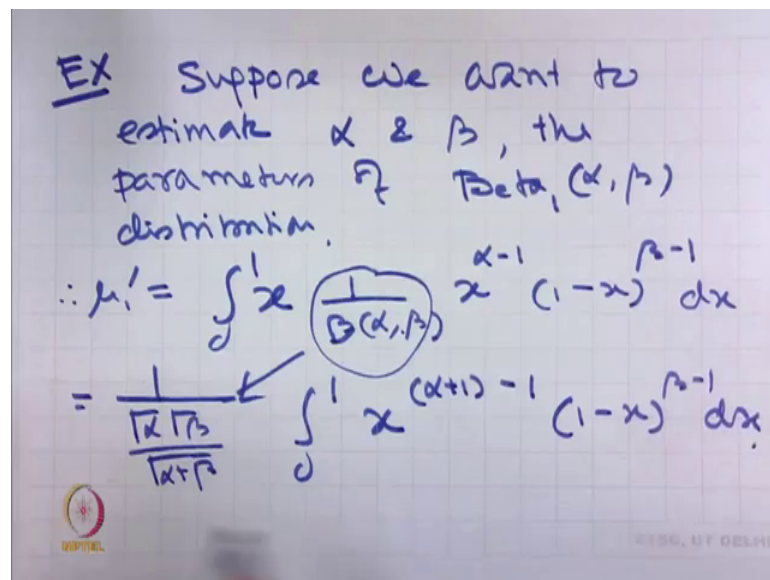

Therefore λ hat is equal to α hat upon m_1 prime where α hat we are found from here and that cancel m_1 prime.

(Refer Slide Time: 21:21)

Therefore lambda hat is equal to m1 prime upon m1 m2 prime minus m1 prime square thus by equating the sample moments with the parametric equations and solving them, we get the estimates consider another example.

(Refer Slide Time: 22:24)

Suppose we want to estimate alpha and beta the parameters of beta 1 alpha beta distribution. Again let us considered mu1 prime 0 to 1 x 1 upon beta alpha beta to the power alpha minus 1 1 minus x to the power beta minus 1 dx is equal to gamma alpha

gamma beta upon gamma alpha plus beta. This I have taken out multiplied by integration 0 to 1 x to the power alpha plus 1 minus 1 into 1 minus x beta minus 1 dx.

(Refer Slide Time: 24:15)

$$= \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} \times \int_0^1 x^{(\alpha+1)-1} (1-x)^{\beta-1} dx$$

$$= \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} \times \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta+1)} = \frac{\alpha}{\alpha+\beta}$$

∴ The sample moment m_1' can be equated with $\frac{\alpha}{\alpha+\beta}$ or $\frac{\alpha}{\alpha+\beta} = m_1'$... (1)

This is equal to gamma alpha plus beta upon gamma alpha gamma beta into 0 to 1 x to the power alpha plus 1 minus 1 1 minus x whole to the power beta minus 1 dx. And this integral gives us beta with alpha plus 1 and beta as there parameters. Therefore, this is equal to gamma alpha plus beta upon gamma alpha gamma beta multiplied by gamma alpha plus 1 gamma beta gamma alpha plus beta plus 1.

This is equal to this cancels and we know that gamma alpha plus is 0 equal to alpha times gamma alpha. So, that cancels this gamma alpha with this and we have left with alpha in a similar way this is equal to alpha plus beta into gamma alpha plus beta. So, this gets cancelled and we are left with alpha plus beta. Therefore, the sample moment can be equated.

Sample first moment can be equated with alpha upon alpha plus beta or alpha upon alpha plus beta is equal to m1 prime. So, this is the first equation.

(Refer Slide Time: 26:21)

In a similar way we can calculate $\mu_2' = E(X^2)$

$$= \int_0^1 x^2 \frac{1}{\Gamma(\alpha, \beta)} \cdot x^{\alpha-1} (1-x)^{\beta-1} dx$$

$$= \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} \int_0^1 x^{\alpha+2-1} (1-x)^{\beta-1} dx$$

$$= \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} \times \frac{\Gamma(\alpha+2)\Gamma(\beta)}{\Gamma(\alpha+\beta+2)}$$

$$= \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} \times \frac{(\alpha)(\alpha+1)\Gamma(\alpha)\Gamma(\beta)}{(\alpha+\beta+1)(\alpha+\beta)\Gamma(\alpha+\beta)} = \frac{\alpha(\alpha+1)}{(\alpha+\beta)(\alpha+\beta+1)}$$

In a similar way, we can calculate μ_2' which is the expected value of X^2 . So, what it is this is equal to integration 0 to 1 x^2 one upon beta alpha beta multiplied by x to the power alpha minus 1 $(1-x)$ to the power beta minus 1 dx .

This is equal to as before $\frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)}$ into 0 to 1 x to the power alpha plus 2 minus 1 $(1-x)$ to the power beta minus 1 dx . This is equal to $\frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)}$ multiplied by now this is giving us beta with alpha plus 2 and this beta. So, we have $\frac{\Gamma(\alpha+\beta+2)}{\Gamma(\alpha+\beta+2)}$ is equal to $\frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha+\beta)}$ which again is alpha into gamma alpha. So, I can write it as alpha into alpha plus 1 into gamma alpha, then gamma beta and this is alpha plus beta plus 1 into alpha plus beta into gamma alpha plus beta. So, after cancellation, we will have alpha into alpha plus 1 upon alpha plus beta into alpha plus beta plus 1.

(Refer Slide Time: 29:10)

$\therefore \frac{\alpha}{\alpha+\beta} = m_1' \quad \dots \text{Sample mean}$

$\frac{\alpha(\alpha+1)}{(\alpha+\beta)(\alpha+\beta+1)} = m_2' \quad \text{sample mean of } x^2$

Then we can solve these two equations & obtain estimated value $\hat{\alpha}$ & $\hat{\beta}$ as estimators for α & β , respectively.

Therefore we have alpha upon alpha plus beta is equal to m1 prime which is the sample mean and alpha, alpha plus 1 upon alpha plus beta into alpha plus beta plus 1 is equal to m2 prime which is sample mean of x square. Then we can solve these two equations and obtain estimated value of alpha hat and beta hat as estimators for alpha and beta respectively. Similar equations can be formed with other distributions and one can obtain the estimates through the method of moments in the above way.

(Refer Slide Time: 31:08)

Maximum Likelihood Estimation. (MLE)

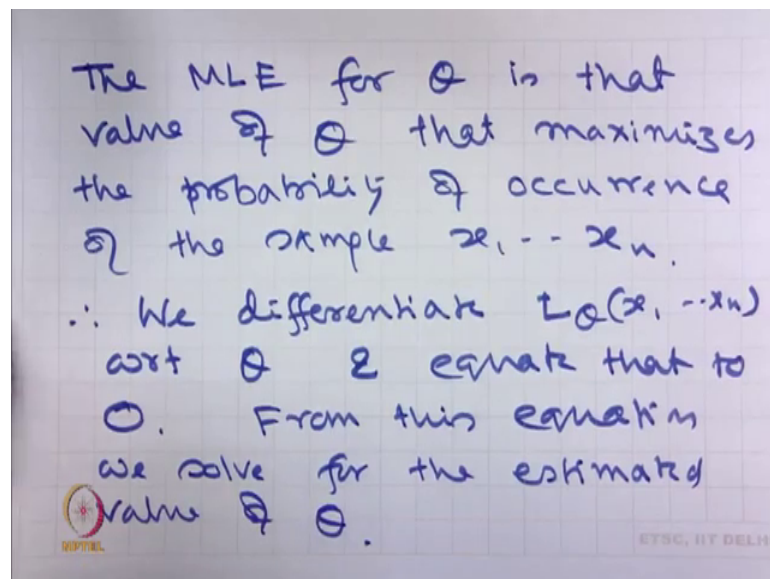

Idea: Suppose we obtained x_1, \dots, x_n as sampled values from $f_0(x)$.

Then the likelihood f^n of this sample is defined as

$$L_0(x_1, \dots, x_n) = f_0(x_1, \dots, x_n)$$
$$= \prod_{i=1}^n f_0(x_i)$$

Now, let me discuss maximum likelihood estimators or estimation. In short, we will write it as MLE. The idea is as follows suppose we obtained x_1, x_2, \dots, x_n as our sample values from $f(\theta, x)$, then the likelihood function of the sample is defined as $L(\theta, x_1, x_2, \dots, x_n)$ is equal to the joint density of x_1, x_2, \dots, x_n . And if the samples are independent it is product of $f(\theta, x_i)$ i is equal to 1 to n . We have already seen the likelihood function when you are discussing gamma inequality. So, this is not something that is new to us.

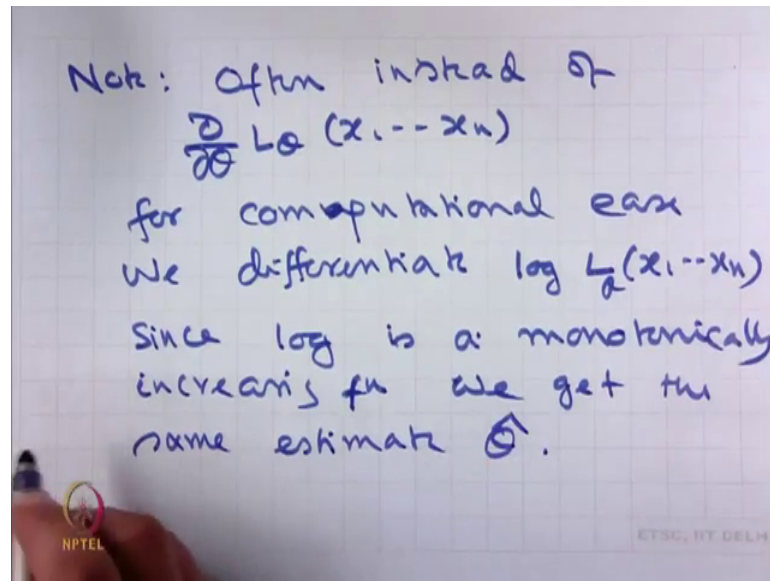

(Refer Slide Time: 33:12).

The idea of likelihood estimation is that we try to obtain that particular value of theta which maximizes the probability of occurrence of the sample x_1, x_2, \dots, x_n . So, the MLE for theta is that value of theta that maximizes the probability of occurrence of the sample x_1, x_2, \dots, x_n .

So, how to obtain that? Therefore, we differentiate $L(\theta, x_1, x_2, \dots, x_n)$ with respect to theta and equate that to 0. From this equation we solve for the estimated value of theta. Of course when we are solving the equation $\frac{\partial L}{\partial \theta} = 0$. We also will have to see that the second order derivative is negative, then only we can ensure that this solution $\hat{\theta}$ is actually giving us the maximum probability for the obtained sample x_1, x_2, \dots, x_n .

(Refer Slide Time: 35:50)

Note often instead of del delta theta of L theta of x 1, x 2 x n. For computational ease, we differentiate log of L theta of x 1, x 2, x n and since log is an increasing function the result is not altered.

(Refer Slide Time: 37:12)

Ex Consider $\text{Ber}(p)$
 $\therefore x_1, \dots, x_n$ are sampled values.
 $\therefore L_{\theta=p}(x_1, \dots, x_n) = p^{\sum x_i} (1-p)^{n-\sum x_i}$
 $\therefore \log L_{\theta=p}(x_1, \dots, x_n) = \sum x_i \log p + (n - \sum x_i) \log(1-p)$
 $\therefore \frac{\partial \log L}{\partial p} = \frac{\sum x_i}{p} + \frac{n - \sum x_i}{1-p} (-1)$
 $= \left[\frac{\sum x_i}{p} - \frac{n - \sum x_i}{1-p} \right] *$

So, let me give you an example. Consider Bernoulli P therefore, x_1, x_2, x_n are sampled values. Therefore, log of x_1, x_2, x_n is equal to we have already seen this is P to the power $\sum x_i$ into $1 - P$ whole to the power $n - \sum x_i$. Therefore $\log L$ therefore, $\log L_{x_1, x_2, x_n}$ is equal to $\sum x_i \log p$ plus $n - \sum x_i \log$ of 1

minus p . Therefore, $\frac{d \log L}{d p}$ because here the parameter is p . We could write θ is equal to p or θ is equal to p . Therefore, $\frac{d \log L}{d p}$ is equal to $\frac{\sum x_i}{p} + n - \frac{\sum x_i}{1-p}$ which will give you $\frac{\sum x_i}{p} - \frac{n - \sum x_i}{1-p}$ is equal to $\frac{\sum x_i}{p} - \frac{n}{1-p} + \frac{\sum x_i}{1-p}$. So, this is what I will need it later when I will be considering the second derivative.

(Refer Slide Time: 39:45)

To obtain the value for which $\log L$ (or L) is maximum we equate

$$\frac{\sum x_i}{p} - \frac{n - \sum x_i}{1-p} = 0$$

or $\sum x_i (1-p) = p (n - \sum x_i)$

or $\sum x_i - p \sum x_i = np - p \sum x_i$

or $\hat{p} = \frac{\sum x_i}{n} = \bar{x}$

But to obtain the value for which $\log L$ is maximum; that is L is maximum. We equate $\frac{\sum x_i}{p} - \frac{n - \sum x_i}{1-p} = 0$ or $\frac{\sum x_i}{p} + \frac{\sum x_i}{1-p} - \frac{n}{1-p} = 0$ or $\frac{\sum x_i (1-p) + p \sum x_i - n}{p(1-p)} = 0$ or $\sum x_i - p \sum x_i + p \sum x_i - np = 0$ or $\sum x_i - np = 0$ or $\sum x_i = np$ or $\frac{\sum x_i}{n} = p$ or $\hat{p} = \bar{x}$.

So, this cancels or \hat{p} is equal to $\frac{\sum x_i}{n}$ is equal to sample mean. Therefore, from here also we find that if we consider p to be \hat{p} to be the sample mean then we get $\frac{d \log L}{d p}$ is equal to 0. Therefore, \bar{x} can be a possible solution provided.

(Refer Slide Time: 42:03)

$\therefore \bar{x}$ is the MLE
 if $\frac{\partial^2 \log L}{\partial p^2} < 0$

$$\frac{\partial^2 \log L}{\partial p^2} = -\frac{\sum x_i}{p^2} + \frac{(n - \sum x_i)}{(1-p)^2} \times \frac{\partial(1-p)}{\partial p} = -!$$

$$\therefore \text{MLE for } p = \bar{x} < 0$$

If $\frac{\partial^2 \log L}{\partial p^2} < 0$ because $\theta = p$ is less than 0. We already had $\frac{\partial \log L}{\partial p} = 0$. So, now, we are differentiating this with respect to p . $\frac{\partial}{\partial p} \left(-\frac{\sum x_i}{p^2} + \frac{(n - \sum x_i)}{(1-p)^2} \right)$. This will be multiplied by minus 1. So, that will make it plus 1 because $\frac{\partial(1-p)}{\partial p} = -1$. Therefore, $\frac{\partial^2 \log L}{\partial p^2} = -\frac{\sum x_i}{p^2} - \frac{n - \sum x_i}{(1-p)^2}$. Since $\sum x_i$ can maximum value be n therefore, $n - \sum x_i$ is positive with this negative sign; this becomes negative, this becomes negative, this is positive, this is positive. Therefore, the whole thing is less than 0. Therefore, MLE for p is equal to \bar{x} .

(Refer Slide Time: 44:40)

The image shows a handwritten derivation on a grid background. It starts with 'Ex Let us consider' followed by the normal distribution PDF: $N_{\mu, \sigma^2}(x)$. The PDF is given as $f(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{1}{2\sigma^2}(x-\mu)^2}$ for $-\infty < x < \infty$. The likelihood function L is then written as $L = \left(\frac{1}{\sqrt{2\pi}\sigma}\right)^n e^{-\frac{1}{2\sigma^2} \sum (x_i - \mu)^2}$. Finally, the log-likelihood function is derived as $\log L = -n \log(\sqrt{2\pi}) - n \log \sigma - \frac{\sum (x_i - \mu)^2}{2\sigma^2}$. There are small logos for 'INTEL' and 'ETSC, IIT DELHI' at the bottom of the page.

Let us now consider normal mu sigma square of x. Therefore,

$f(x)$ is equal to $\frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{1}{2\sigma^2}(x-\mu)^2}$ for $-\infty < x < \infty$. Therefore, L of course, mu sigma square which you are often write as well theta is equal to $\left(\frac{1}{\sqrt{2\pi}\sigma}\right)^n e^{-\frac{1}{2\sigma^2} \sum (x_i - \mu)^2}$. Therefore $\log L$ is equal to $-n \log \sqrt{2\pi} - n \log \sigma - \frac{\sum (x_i - \mu)^2}{2\sigma^2}$. This is from here minus $n \log \sigma$ minus $\sum (x_i - \mu)^2$ divided by $2\sigma^2$.

(Refer Slide Time: 47:03)

$$\begin{aligned}\log L &= -n \log(\sqrt{2\pi}) - \frac{n}{2} \log \sigma^2 \\ &\quad - \frac{\sum (x_i - \mu)^2}{2\sigma^2} \\ \therefore \frac{\partial \log L}{\partial \mu} &= + \frac{2 \sum (x_i - \mu)}{2\sigma^2} \\ &= \frac{\sum (x_i - \mu)}{\sigma^2}\end{aligned}$$

Or if we write it with sigma square as the parameter, if we write sigma square as the parameter, then we can write log L is equal to minus n log root over 2 pi minus n by 2 log sigma square minus sigma x i minus mu whole square upon 2 sigma square. Therefore, del log L del mu is equal to this gets cancelled. Because this gives 0, this gives 0 and what we are left with is minus 2 into sigma x i minus mu. Now this is with minus sign. So, that makes it plus upon 2 sigma square is equal to sigma x i minus mu upon sigma square and del log L.

(Refer Slide Time: 48:48)

$$\begin{aligned}\frac{\partial \log L}{\partial \sigma^2} &= -\frac{n}{2\sigma^2} + \frac{\sum (x_i - \mu)^2}{2} \frac{1}{(\sigma^2)^2} \\ \therefore \text{To solve them we need} &\quad \text{to equate the partial} \\ &\quad \text{derivatives with 0.} \\ \text{From eq 1: we have} & \\ \frac{\sum (x_i - \mu)}{\sigma^2} &= 0 \\ \sum x_i - n\mu &= 0 \quad \therefore \hat{\mu} = \frac{\sum x_i}{n}\end{aligned}$$

Del sigma square is equal to from here we are differentiating it with respect to sigma square. Therefore, log of sigma square derivative is 1 upon sigma square. So, what we are getting is minus n upon 2 sigma square. And from the other one, we are getting plus sigma x i minus mu whole square upon 2 into 1 upon sigma square whole square. Because if you look at this, it is 2 sigma square. So, sigma square to the power minus 1. So, when we are differentiating we are getting that minus will make it plus and 1 upon sigma square whole square. Therefore, to solve them we need to equate the partial derivatives with 0 from equation 1. We have minus x i minus mu upon sigma square is equal to 0. Therefore, sigma x i minus n mu is equal to 0 therefore, mu hat is equal to sigma xi upon n. So, that is the estimate for mu.

(Refer Slide Time: 52:08)

From the 2nd eq

$$-\frac{n}{2\sigma^2} + \frac{\sum(x_i - \mu)^2}{2(\sigma^2)^2} = 0$$

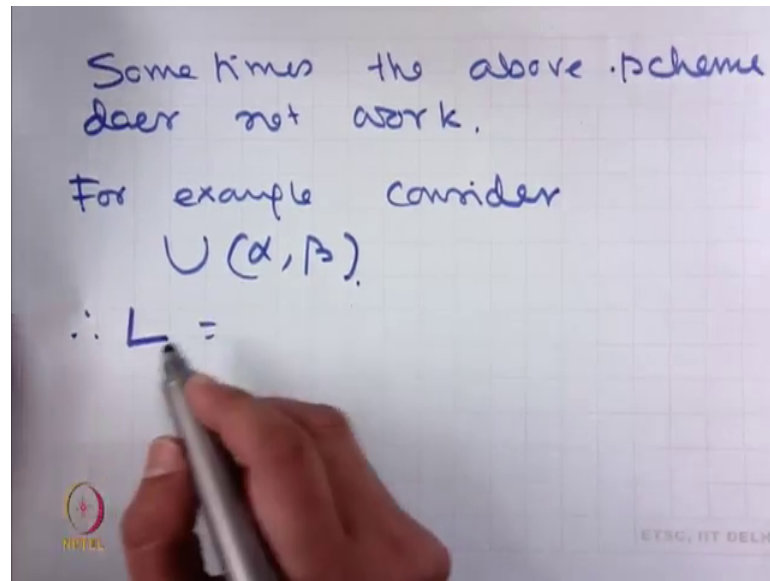

We get $\frac{\sum(x_i - \mu)^2}{2(\sigma^2)^2} = \frac{n}{2\sigma^2}$

$$\therefore \hat{\sigma}^2 = \frac{\sum(x_i - \mu)^2}{n}$$

$$\therefore \hat{\sigma}^2 = \frac{\sum(x_i - \bar{x})^2}{n}$$

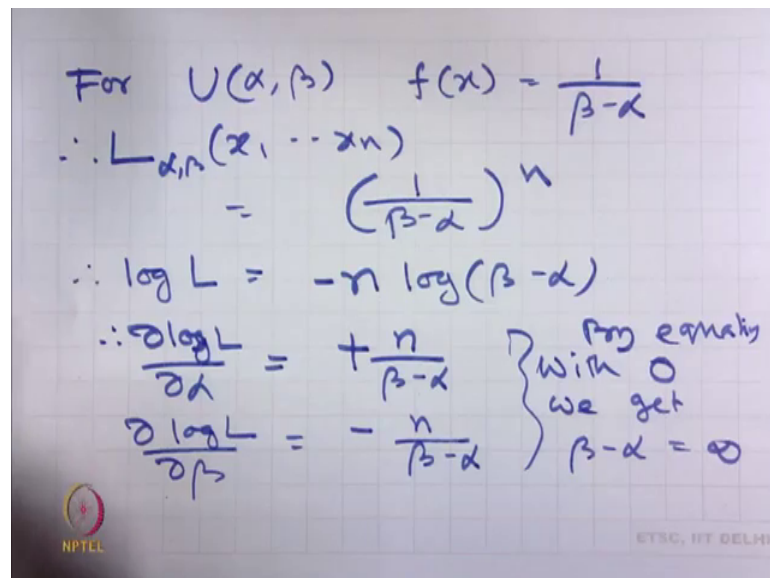

From the second equation which is minus n upon 2 sigma square plus sigma x i minus mu whole square upon 2 sigma square square is equal to 0. We get sigma x i minus mu whole square upon 2 sigma square square is equal to n upon 2 sigma square. So, this cancels one of these cancels. Therefore sigma square hat is equal to sigma x i minus mu whole square upon n. But we do not know mu, we know only mu hat. Therefore, sigma square hat is equal to sigma x i minus x bar whole square up on n. So, that is the maximum likelihood estimate for sigma square. And we already knew that this is not an unbiased estimator because the unbiased estimator for sigma square is sigma x i minus x bar whole square upon n minus 1. When the mu is unknown to us however, MLE gives us these to be the estimator. [FL]

(Refer Slide Time: 54:36)

Sometimes, the above trick or above scheme does not work. For example, consider uniform alpha beta.

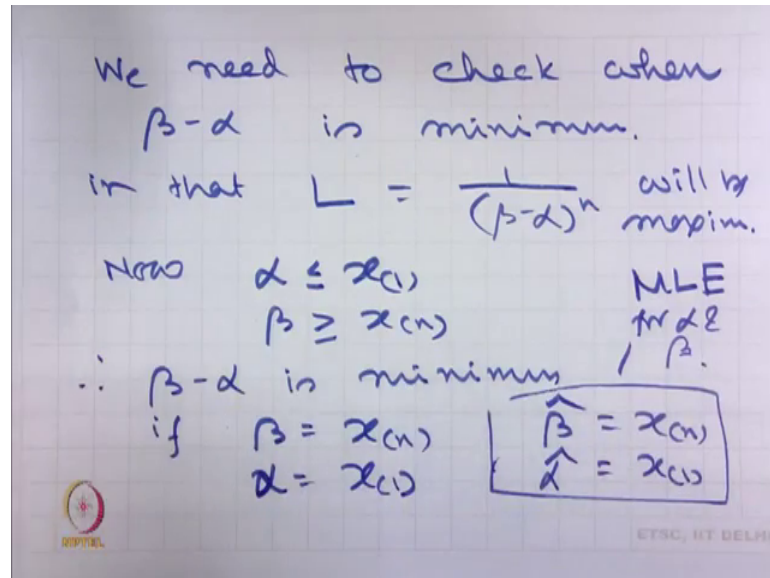

(Refer Slide Time: 55:20)

Therefore, log is equal to for uniform alpha beta $f(x)$ is equal to 1 upon β minus α . Therefore, the likelihood function of x_1, x_2, x_n is equal to 1 upon β minus α whole to the power n and this does not give us any solution. Therefore, $\log L$ is equal to $n \log \beta$ minus α with a minus sign. Therefore, $\frac{\partial \log L}{\partial \alpha}$ is equal to minus n upon β minus α and now make it plus and $\frac{\partial \log L}{\partial \beta}$ is equal to

minus n upon beta minus alpha. By equating 0 by equating with 0, we get beta minus alpha is equal to infinity. Therefore that does not give us a solution. What we can do in the following way?

(Refer Slide Time: 57:08)

We need to check when beta minus alpha is minimum in that case L is equal to 1 upon beta minus alpha whole to the power n will be maximum. Now alpha has to be less than equal to $x_{(1)}$ and beta has to be greater than equal to $x_{(n)}$. This is the first order statistics, this is the nth order statistic. Therefore, beta minus alpha is minimum.

If beta is equal to $x_{(n)}$ and alpha is equal to $x_{(1)}$, therefore $x_{(n)}$ is the beta hat and alpha hat is equal to $x_{(1)}$. These are the MLE for alpha and beta with that I stop here today. In the next lecture, I will give you some properties of maximum likelihood estimator and also I will talk about interval estimation.

Thank you.
