IVP $Ly(x) = f(x)$, $y(x_0) = y_0$, $y'(x_0) = y'_0$ (IVP) — ①

Eq. ① Can be split into two equations

$\begin{cases} Ly(x) = 0 \\ y(x_0) = y_0 = \alpha \\ y'(x_0) = y'_0 = \beta \end{cases}$	$\begin{cases} Ly(x) = f(x) \\ y(x_0) = 0, y'(x_0) = 0 \\ y_p(x) \end{cases}$
--	---

$y_c(x)$

$y(x) = y_c(x) + y_p(x)$

$y(x_0) = y_c(x_0) + y_p(x_0) = \alpha + 0 = \alpha$

$y'(x_0) = y'_c(x_0) + y'_p(x_0) = \beta + 0 = \beta$

$\begin{cases} Ly(x) = 0 \\ y(x_0) = y_0 = \alpha \\ y'(x_0) = y'_0 = \beta \end{cases}$	$\begin{cases} Ly(x) = f(x) \\ y(x_0) = 0, y'(x_0) = 0 \\ y_p(x) \end{cases}$
--	---

$y_c(x)$

$y(x) = y_c(x) + y_p(x)$

$y(x_0) = y_c(x_0) + y_p(x_0) = \alpha + 0 = \alpha$

$y'(x_0) = y'_c(x_0) + y'_p(x_0) = \beta + 0 = \beta$

$\Rightarrow Ly(x) = f(x)$, $y(x_0) = \alpha$, $y'(x_0) = \beta$

$L = \frac{d^2}{dx^2} + P(x) \frac{d}{dx} + Q(x)$

The image shows a Notepad window with the following handwritten derivations:

$$\Rightarrow y_p(x) = \int_{x_0}^x G(x, \xi) f(\xi) d\xi$$

$$y_p(x_0) = \int_{x_0}^{x_0} G(x, \xi) f(\xi) d\xi = 0$$

$$\text{Also } y_p'(x) = \frac{d}{dx} \int_{x_0}^x G(x, \xi) f(\xi) d\xi = \int_{x_0}^x \frac{\partial G(x, \xi)}{\partial x} f(\xi) d\xi + G(x, x) f(x)$$

$$y_p'(x_0) = \int_{x_0}^{x_0} \frac{\partial G(x, \xi)}{\partial x} f(\xi) d\xi + \underbrace{G(x_0, x_0)}_{=0} f(x_0)$$

$$\Rightarrow y_p'(x_0) = 0$$

In the last lecture we have started with the Green functions and now I want to develop the theory to solve initial value problem and the boundary value problem with the help of the Green function. So, I start with the first one, that is initial value problem. So, in this case, suppose I have my second order, any differential of equation, so that is $Lyx = fx$, this is the nonhomogeneous equation and in that case, I have the initial condition that y at x_0 is some value I am taking.

So, let us take it as y_0 , so this is my y_0 and another initial condition I have taken y dash at x_0 , so I call it y dash. So, this is my initial condition, and so this is my corresponding initial value problem. And I want to solve this equation with the help of the Green's function. So, this is my equation number 1. So, equation 1 can be split it into 2 equations, so we split this one with two types of equation, the first one is L of y_x equal to 0.

This is the corresponding homogeneous equation satisfying the initial condition, that is y_0 and y dash x_0 , so this is given to me. I can call it has α and β also. And another equation I define as the non-homogeneous equation that is the equation we have, so this is my $L(yx) = fx$ and which is satisfying the homogeneous initial condition with the help of, and y dash $x_0 = 0$. Solving this equation I get my solution that will be my y_{cx} and solving this equation, I will get the solution and I call it y_{px} .

So, in that case I know that my solution y_x for the equation number 1 will be the linear combination of $y_{cx} + y_{px}$. And if you see this one, then my y at x_0 will be y_c at $x_0 + y_p$ at x_0 and y_c is the solution of this corresponding homogeneous, so this will be α and $+ 0$, so

this will be α and $y'(x_0)$ will be γ at $x_0 + y'(x_0)$ and this will be again, this will be β and zero and it will be β .

Okay, so this solution will satisfy, so my $y(x)$ the solution I can write and that solution will satisfy the corresponding initial conditions.

So this is my solution of equation number 1 and this solution is satisfying the corresponding initial conditions given to me. Now, so we start with the general [equation](#), so I have a general [equation](#) second order differential equation $Ly = f(x)$ is equal to my $f(x)$, right. And then I have my initial condition, $y(x_0)$, I define it α and $y'(x_0)$, I define it β . So, this is the, and my L in this case I am taking $d^2y/dx^2 + p(x)dy/dx + q(x)y = f(x)$, so these are same as we have defined the last class.

So, this is a linear second order differential operator. So, in this case, I will try to find out the Green's function. So, first I will solve the equation $Ly = 0$, so this equation I solving with the given α and $y'(x_0) = \beta$. But I know that, one thing I also know, that also I know that L of $g(x)$ that is also equal to this one and I know that for x is not equal to x_0 , so this equation becomes, is equal to 0.

So, it means that whatever the Green function I am going to find out, so this Green function satisfy this condition also. It means whatever the corresponding homogeneous equation I am solving, from where I will get my Green function. So, from here I can say that my Green function will also satisfy the initial condition, $G(x_0) = \alpha$, $G'(x_0) = \beta$, because G is a function of two variable here, so from here I will say that $G(x_0, x_0) = \alpha$, this equal to β . So, this is I can define from my Green function.

So, now I want to solve this one, so I defined my function $y(x) = c_1y_1(x) + c_2y_2(x)$, so this one we have defined. With the help of this y_1 and $y_2(x)$, we have found that my c_1 , that is a with the help of variation of parameter also, I found that my c_1 is $-y_2$ and this is x divided by dx and my $c_2(x)$ is $y_1(x) f(x)$ and, so from here, so this is the corresponding c_1, c_2 I found and to write the general solution, I will get my $y(x)$ of the corresponding equation I call it equation number 1/

So the general solution equation number 1 I can write as $y(x) = c_1y_1(x) + c_2y_2(x) + y_p(x)$, okay, so $y(x)$ is $c_1y_1(x) + c_2y_2(x) + y_p(x)$ I can write as, so c_1 is this one, so from here I can write it will be equal to - of

y_2 , so I call it X_i , $f(X_i)$ into $y_1 x \frac{d}{dx} X_i + y_1 X_i f(x)$, $w(X_i)$, $y_2 x \frac{d}{dx} X_i$, so this one I can write. So, from here, we can write as, this is equal to $c_1 y_1 + c_2 y_2 +$ and this integral I can write as $y_1 X_i y_2 x - y_2 X_i y_1 x$ divided by the Wronskian, so this one $f(X_i) \frac{d}{dx} X_i$.

So these are my solution, so that is my solution. So, from here I can define that my general solution is now I can say that this is $c_1 y_1 + c_2 y_2 +$, so this integral, actually if you see, that X_i belongs to, so in this case my X_i I can say that this X_i is, so I can take this integral between x_0 to x . So, I can write this one as x_0 to x my Green function as $x X_i$ and this is $f(X_i) \frac{d}{dx} X_i$, so this is my general solution for the equation number 1.

So, from here, I can define that my Green function will be $-y_2 X_i$ when x is less than X_i and $y_1 X_i$ over Wronskian when x is greater than X_i . So, this is my Green function in that case. To $y_1 x$ and this will be $y_2 x$, so this one my. So from here, so my particular solution I can say that my $y_p x$ will be x_0 to x , $f(X_i) \frac{d}{dx} X_i$. So, this is the particular solution I found. Now from here, what about if I apply my y_p at x_0 . So, if I apply this one, this integral from x_0 to x_0 , $d X_i$ and this value will be 0.

Also, y_p dash, so I am taking the derivative with respect to x . So, with the help of the Leibnitz theorem, this can be written as from x_0 to x , so this will become $\frac{d}{dx} G$ by $\frac{d}{dx} x f(X_i) \frac{d}{dx} X_i +$ putting the value of x here and this 2 to X_i will be the value of this, so that will be G_{xx} and it will be equal to $f(x)$ and this x **naught** is a constant so we will get this. So from here I will get this one, so this can be written as, so from here if I want to apply what will be value of y_p dash at x_0 , so this will be again x_0 to x_0 , that is my G_x , this one $+ G$ of x_0 and my f of x_0 .

So this one I will continue, so this value is equal to 0, and what about this one, this is also 0, because I know that my x_0 is the initial condition and G_x is the solution of the corresponding homogeneous equation, so this is equal to 0 and so from here I can say that y_p , whatever the particular solution I am having that solution corresponding homogeneous initial condition that is, this is equal to 0 and this is equal to 0.

So we start with the, if you see this one, we have started with a problem, this one and then we split this one into two parts so this one we have used to find out the Green functions and the corresponding values of c_1 and c_2 , and then with the help of the particular solution we found

we have showed that they satisfy this homogeneous initial condition, and then that is ypx is our particular solution.

(Refer Slide Time: 16:30)

$$L y(x) = y'' + 4y = f(x) = 1 \Rightarrow \boxed{y'' + 4y = 1}$$

$$\left. \begin{array}{l} y(0) = 0 \\ y'(0) = 1 \end{array} \right\} \begin{array}{l} \text{initial} \\ \text{Cond.} \end{array}$$

$$\left\{ \begin{array}{l} L y(x) = 0 \\ y(0) = 0 \\ y'(0) = 1 \end{array} \right. \Rightarrow \begin{array}{l} y'' + 4y = 0 \\ m^2 + 4 = 0 \Rightarrow m = \pm 2i \\ y_1(x) = \cos 2x, \quad y_2(x) = \sin 2x \end{array}$$

$$\Rightarrow \boxed{y_c(x) = C_1 \cos 2x + C_2 \sin 2x}$$

$$y_c(0) = C_1 \cos 2 \cdot 0 + C_2 \sin 2 \cdot 0 = 0 \Rightarrow C_1 + 0 = 0 \Rightarrow \boxed{C_1 = 0}$$

$$y_c'(x) = -C_1 \cdot 2 \sin 2x + 2C_2 \cos 2x \Rightarrow 2C_2 \cos 2x = y_c'(x)$$

$$y_c'(0) = 2C_2 \cos 2 \cdot 0 = 1 \Rightarrow \boxed{C_2 = \frac{1}{2}}$$

$$\Rightarrow \boxed{y_c(x) = C_1 \cos 2x + C_2 \sin 2x}$$

$$y_c(0) = C_1 \cos 2 \cdot 0 + C_2 \sin 2 \cdot 0 = 0 \Rightarrow C_1 + 0 = 0 \Rightarrow \boxed{C_1 = 0}$$

$$y_c'(x) = -C_1 \cdot 2 \sin 2x + 2C_2 \cos 2x \Rightarrow 2C_2 \cos 2x = y_c'(x)$$

$$y_c'(0) = 2C_2 \cos 2 \cdot 0 = 1 \Rightarrow \boxed{C_2 = \frac{1}{2}}$$

$$\boxed{y_c(x) = \frac{1}{2} \sin 2x}$$

$$\Rightarrow y_p(x) = \int_n^x G(x, \xi) f(\xi) d\xi = \int_n^x G(x, \xi) d\xi$$

$$= \int_n^x \frac{\cos 2\xi \sin 2x - \cos 2x \sin 2\xi}{W(\xi)} d\xi$$

$$W(x) = \begin{vmatrix} \cos 2x & \sin 2x \\ -2 \sin 2x & 2 \cos 2x \end{vmatrix} = 2$$

So, now, let us take one example, then the things will be more clear, so let us take one example, example number 1, I want solve my equation, so $L yx$ I am taking y double dash + $4y = fx$ and that I am choosing just 1. So, basically I am solving, if you see, y double dash + $4y = 1$, so this one we are solving. And I already know that how to solve this one because this is a linear second order equation with constant coefficients and the right hand side function is just 1.

But I want to solve this one with the help of Green function. So, first I will solve the equation, $L(yx) = 0$, now I putting the initial condition also, so I will define at $y Pi = 0$ and y

dash $\pi = 1$, so this is my initial condition. So I want to solve this one, so this is initial condition, y dash $\pi = 1$. So I want to solve this one. So if I solve this one, then from my previous knowledge, I know that $4y = 0$ and then I can find out my corresponding **characteristic** equation that will be $m^2 + 4 = 0$.

And from here, I will get my m is $\pm 2i$ and from there I can define my solution $y_1(x)$ as $\cos 2x$ and $y_2(x)$ as $\sin 2x$. So from here, I can define my **linearly independent** solution that is $\cos 2x$ and $\sin 2x$. So from here, I will get my solution $y(x)$ will be \cos , so I want to define this one, so this one will be $c_1 \cos 2x + c_2 \sin 2x$. Now, I will try to find out the value of c_1 and c_2 from here. So, this is my corresponding complimentary solution.

So complimentary solution I can find out, and then from here I can find my, it is given that y at π that is giving to me, so this will be $c_1 \cos 2\pi + c_2 \sin 2\pi$ and that value is given equal to 0. So, from here I know that, $\cos 2\pi$ will be 1, so it will be $c_1 +$ and then it will be $0 = 0$, from here I calculate that $c_1 = 0$. And then, I will also define y dash at x . So y dash $= x$, I will define, so this will be $-c_1 \sin 2x + 2c_2 \cos 2x$, but this value is already, because c_1 is already 0.

So from here I will get, $2c_2 \cos 2x = 1$. So this the derivative I have is that is equal to my y dash because c_1 is already 0 from this initial condition, first initial condition. So, from here I can say that my y dash at π will be $2c_2 \cos 2\pi$ and that is equal to 1. So, from here, I can say, and the $\cos 2\pi$ is 1. So from here I can say, that my c_2 will be $1/2$. So from here, I am able to find my $y(x)$, will be c_1 is 0, so it will be, of $\sin 2x$.

So this is I am able to find. Now, I want to find the corresponding Green functions with the help of this one, so from here I can say that my corresponding Green functions, so now I want to find my $y_p(x)$, so $y_p(x)$ will be from π to x , $d\xi$. So $f(\xi)$ is 1 here in this case, so it will be π to x $d\xi$, where I know that my Green function will be in this case, it will be $\cos 2\xi$ into $\sin 2x - \cos 2x \sin 2\xi$ divided by the Wronskian, so the Wronskian into $d\xi$.

So, from here, the Wronskian I know, that the Wronskian in this case will be, so this is my $\cos 2x$ and this is $\sin 2x$, so this will be $-2 \sin 2x$, and this will be $2 \cos 2x$ and that value will be equal to 2, so in this case I will get the Wronskian that is equal to 2. So generally we take the positive value if it is coming negative.

$$\Rightarrow y_p'(x-n) = \frac{1}{2} \int_n^x 2 \cos 2(x-\xi) d\xi + G(n, n) = 0$$

$$\Rightarrow y_p'(x-n) = 0 \Rightarrow L y_p(n) = f(n) = 1$$

$$y_p(n) = 0 = y_p'(n)$$

$$\Rightarrow y_p(x) = \frac{1}{4} - \frac{\cos 2x}{4}$$

$$\Rightarrow \text{General Sol. } y(x) = \frac{1}{2} \sin 2x + \frac{1}{4} - \frac{\cos 2x}{4}$$

Use operator method

$$(D^2 + 4)y(x) = 1 \Rightarrow y_p(x) = \frac{1}{D^2 + 4} \cdot 1$$

$$\Rightarrow y_p(x) = (D^2 + 4)^{-1} e^{0x} = \frac{1}{4}$$

5/5
5:45 PM
04-May-19

$$\Rightarrow y(x) = C_1 \cos 2x + C_2 \sin 2x + \frac{1}{4}$$

$$y(0) = C_1 \cos 2 \cdot 0 + C_2 \sin 2 \cdot 0 + \frac{1}{4} = 0$$

$$\Rightarrow C_1 + \frac{1}{4} = 0 \Rightarrow C_1 = -\frac{1}{4}$$

$$y'(x) = -2C_1 \sin 2x + 2C_2 \cos 2x$$

$$y'(0) = -2C_1 \sin 2 \cdot 0 + 2C_2 \cos 2 \cdot 0 = 1$$

$$\Rightarrow 2C_2 = 1 \Rightarrow C_2 = \frac{1}{2}$$

$$\Rightarrow y(x) = -\frac{1}{4} \cos 2x + \frac{1}{2} \sin 2x + \frac{1}{4}$$

$$y(x) = \frac{1}{2} \sin 2x + \frac{1}{4} - \frac{1}{4} \cos 2x$$

So, from here, I can define my ypx will be from Pi to x and this will be half, so 1 by 2 and this one I can write as $\sin 2x - X_i d X_i$. Okay, so this one I can define from here and if I solve this one, so this is my ypx. So, ypx I am able to found, so this ypx now I take, what will be the value of yp at Pi? So yp at Pi this will be the integral. From Pi to Pi, sin to x - Xi d Xi and this will be value equal to 0, then yp dash x will be again.

So, in taking the derivative of, so it would be $\cos 2x - X_i$ into $2 d X_i +$ then we found the Green function, so this will be xx that will be the value. Because I am putting this upper limit in the function and then the function fx in this case it will be 1. So, from here, I just define that what will be the value of yp dash at $x = \text{Pi}$. So, in this case, this integral become 0, $2 \cos + G \text{Pi Pi}$ and this is equal to 0 and this will be equal to 0 because $G \text{Pi Pi}$ is the solutions of the corresponding homogeneous equations.

From here, I can say that my yp at x equal to Pi will be 0. So, from here I can say that my ypx Lyp that my L of $yp = fx$ that is equal to 1 and it is satisfying the homogeneous initial condition and that is this equal to 0 and this is again $yp \text{ dash} = 0$. So from here, I am able to solve this one and now, if I solve the integral value, then my yp will be, if I just want to take the integration of this one, so from here, my yp x will be in this case, it will be 1 by 4.

So, if I just, ycx is half so it will be $1 \text{ by } 4 - \cos 2x \text{ by } 4$, so then, my general solution yx will be $1 \text{ by } 2 \sin 2x + 1 \text{ by } 4 - \cos 2x \text{ by } 4$, so that will be my general solution for the given equation. If I solve the same equation with the way we have solved in the previous lecture and you can verify also that, if I use the operator method, then I can find this equation as d

square + 4 yx = 1 and from here, my ypx I can define as 1 over d square + 4 into 1 and this one I know that we can write as d square + 4 inverse and 1, this 1 I can write as 0x.

And from here, I find that putting the value of 0 instead of d, so it will get 1 over 4. So my ypx in this case it will be 1 by 4.

⇒ $G(x, \xi) = \begin{cases} c_1 x + d_1 & x < \xi \\ c_2 x + d_2 & x > \xi \end{cases}$

⇒ ① $G(x, \xi)$ is Continuous at $x = \xi$.

$$\Rightarrow G(x, \xi) = \begin{cases} c_1 x + d_1 & x < \xi \\ c_2 x + d_2 & x > \xi \end{cases} \quad \text{--- } \otimes \quad 0 < \xi < 1$$

$$\Rightarrow \textcircled{1} \quad G(x, \xi) \text{ is continuous at } x = \xi.$$

$$\Rightarrow c_1 \xi + d_1 = c_2 \xi + d_2 \Rightarrow (c_1 - c_2)\xi + (d_1 - d_2) = 0$$

$$\Rightarrow G(0, \xi) = c_1 \cdot 0 + d_1 = 0 \Rightarrow \boxed{d_1 = 0}$$

$$\Rightarrow \frac{\partial G(x, \xi)}{\partial x} = \begin{cases} c_1 & x < \xi \\ c_2 & x > \xi \end{cases} \Rightarrow \frac{\partial G(x, \xi)}{\partial x} = \boxed{c_2 = 0}$$

$$\Rightarrow G(x, \xi) = \begin{cases} c_1 x & x < \xi \\ d_2 & x > \xi \end{cases}$$

So from here I can find my solution and then, so if I solve this one, my general solution will be, so this general solution in that case will be $c_1 \cos 2x + c_2 \sin 2x + 1$ by 4 and then apply my initial condition, so my y of π will be $c_1 \cos 2\pi + c_2 \sin 2\pi + 1$ by 4 and this value is given to me is equal to 0. So, from here, so this is 0, this is 1. So from here, I can get my $c_1 + 1$ by 4 = 0. So my c_1 will be -1 by 4.

And then, I will take the derivative of the solution, y' at x , so this one will get $-2c_1 \sin 2x + 2$ times $c_2 \cos 2x$, so this is my derivative and then I put value equal to π . So, in that case, it will be $-2c_1 \sin 2\pi + 2c_2 \cos 2\pi$, and that value is given to me, that is equal to 1. So, from here, I can say, so my c_1 is already -1 by 4. So, this one I can write as 2 times c_2 , so $\cos 2\pi$ is 1, so I can write this as -2 . So, c_1 is but this value is always 0, so this is equal to 0 and from here, I will get $2c_2$ and that is equal to 1.

So, from here, my c_2 is 1 by 2. So my c_1 is -1 by 4 and c_2 is 1 by 2. So, from here, I can write my general solution that is $y(x)$ is equal to from here, so c_1 is -1 by 4, so it is -1 by 4 $\cos 2x$, c_2 is half so half $\sin 2x + 1$ by 4 and from here I can write that it is equal half $\sin 2x + 1$ by 4 -1 by 4 $\cos 2x$, so this is the same solution we got with the help of Green function. So, this solution and the solution we have solved using the Green function, so this and this, both are same.

So from here we verify that, whether we are solving this equation with the help of the operator method or we are solving the same equation with the Green functions, we are getting

the same solution. Now, I take the, so this is the initial value problem that I have taken, now let us start with the boundary value problem. So I take the boundary value problem. So, in the boundary value problem, so let us see that how we are able to find the Green functions.

So let us take one example of that boundary value problem, so let us solve this equation. I am going to solve the equation $y'' = f(x)$ with the boundary condition, so boundary condition I am taking $y(0) = 0$ and $y'(1) = 0$, so this is the boundary condition I am taking. So this is the mixed boundary condition. It is, if we see, this is a Dirichlet type boundary condition and this is a Neumann boundary condition. So it is a mixed type of, we have a function and its derivative.

So, in this case, I will solve the Green function. So, the same way we will split this one into two parts; first one I will solve like this one $y'' = 0$ with our boundary condition, whatever the boundary condition we have and then I will solve the whole equation, $y'' = f(x)$ with the homogeneous boundary condition. But in this case, the boundary conditions are already homogeneous, so the same boundary condition I am putting for the both the equation.

Now from here, and I also know, that the second derivative remains $\frac{d^2}{dx^2}$, this will be equal to the Dirac Delta function, okay. And this will be equal to 0 when x is not equal to ξ . It means that in that case also, I can say that 0 will be 0 and $G(x, \xi)$ at $x = \xi$, this will be 0 in this case. Now, if I want to solve this one, so solving my $y'' = 0$, taking the integration one more time, so I am taking my y' is equal to some constant c and from here I will get my y I will write as $cx + d$. So, this is my equation of the line, okay.

So, this my $y = cx + d$. So from here, and now in this case my x , so if you see here, my x is lying between 0 and 1. Because its value is given at this one. From here, I can say that this is my solution of the equation and x belongs to, I can say, it is belonging from 0 to 1. Now, from here, I can define my Green's function. So, this Green function will be $cx + d$ when x is less than ξ and so I can just define as $c_1 x + d_1$ and then $c_2 x + d_2$ is greater than ξ .

So, this one is a Green function we know, I can define from here and then I can find the value of c_1, d_1, c_2, d_2 . So, this is I am doing with the help of the properties of the Green functions, and from here, I will apply the properties. The first property is I am applying that my function G is continuous at $x = \xi$.

Because you can find out the Green function by solving this homogeneous equation also and then we put the boundary condition and then we can find the corresponding coefficients. But here I am applying the another method that is with the help of the properties of the Green function. From here, I can write that $c_1 X_i + d_1 = c_2 X_i + d_2$. So from here, I can write my $c_1 - c_2 X_i + d_1 - d_2$ that is equal to 0, okay.

Now, I also know that this conditions, the boundary conditions are satisfied for the given function, so because in this case, I already know that I can, from the another equation, the jump discontinuity, I can find the another equation and using those equations, we can have a two equation and the 4 variables, c_1 , c_2 , d_1 , d_2 to find.

So, what I can do is that, I can apply this boundary condition for the given function also. So this the corresponding Green function, so from here I can say that G of 0 X_i , so G of 0 X_i because x is less than X_i I am taking and X_i is in this case, will be lying between 0 and 1. So I can say that this will be c_1 , so it will be c_1 into 0 + d_1 and that value is given to me. So, from here, I can say that d_1 is equal 0. So, from here I can able to eliminate the d_1 .

Now, I also know that G , the $\frac{dG}{dx}$, so let us find out this one, that what will be the value of this one, so I just want to find out this one. So this value equal to, so it will be c_1 , I am taking the derivative with respect to x , when x is less than X_i and it will be c_2 when x is greater than X_i . And from here, I am able to find this value, so from here, I can put my $\frac{dG}{dx}$ at 1 X_i . So it means the, so I am putting $x = 1$ here.

So I am taking this condition that x is greater than X_i . So, in this case, I can say that my c_2 , this is given to me, and this value is equal to 0. So from here, I can also able to eliminate $c_2 = 0$. So from here, I can now write my Green function. So this Green function is $c_1 x$ when x is less than X_i and c_2 , so it is d_2 when x is greater than X_i .

So, now we have only two c_1 and c_2 . Now, what I will do, I will take the help of this properties, because just I wanted to use this one so with the help of this continuity equation and jump equation, I can find the value of c_1 and d_1 .

So this part I will do now for this Green function because this is the Green function after

putting the boundary condition.

So from here, first property it is continuous at X_i so from here I can say that $c_1 X_i$ into $X_i = d_2$. So this is one of the equation and from the second property, that **second** property is that $\frac{\partial G}{\partial x}$ has the jump discontinuity of magnitude 1 about $x = X_i$. So, from here, I can say that $\frac{\partial G}{\partial x} - \frac{\partial G}{\partial x} = 1$. From here, I can say that, so this is my d_2 , so it will be $0 - c_1$ and that is equal to 1.

So, from here, I can that my c_1 is -1. So once I have $c_1 = -1$, from here with the help of this one, so $c_1 = -1$, d_2 in this case will be - of X_i . So with the help of this one, I am able to find my Green function now, so c_1 , this is the Green function. So c_1 , so I can define this function as $-x$ when x is less than X_i and d_2 is $-X_i$ so this is $-X_i$ when $x = X_i$, so this is my Green function.

So, once I am able to define this Green function, so now, I can find my particular solution $y_p(x)$, so $y_p(x)$ will be from 0 to 1 $G, d X_i$. So this one I want to find. Now, so, with the help of this one, $y_p(x)$ is equal to from 0 to 1, G_x this one, I am able to find my $y_p(x)$. So, in this case, because if you see we have started with the equation with $f(x)$ is unknown, so now I define the $f(x)$, let us take a simple one. So let us take $f(x)$ equal to x square.

So if I take x square, then my $y_p(x)$ I can define as from 0 to x , my G_x into x square into X_i square $d X_i +$ from x to 1, $d X_i$. Why I have done that, because the Green function is defined for in the p 's y 's form when x is less than X_i , this value and this value so from here, I can define my, so this will be, so when my X_i is lying between 0 to x , it means when my X_i is, so from here I can say, in this condition, my X_i is less than x and in this one, my X_i is greater

than x , because ξ is lying between x and 1.

So when x is greater than ξ my this is value ξ , so I can put from here 0 to x and then this will be $-\xi$ into ξ square and $d\xi + x$ to 1 and this value is $-x$, so it will be $-x \xi$ square $d\xi$. This one can be written as ξ square $d\xi$. So, I will just solve this one, 0 to x - of ξ cube $d\xi - x$ to 1, so this x I can take outside, this will be ξ square $d\xi$, okay.

Now, I will solve this further, so from here, I will get, so it will be ξ^4 by 4 applying the conditions here, $-x$ and this will be ξ^3 by x to 1. So, from here, I will get 1 by 4, so it will be $x^4 - 0 - x$ by 3 and this will be $1 - x^3$, so from here this one, I am putting this limit. So once I get this value, I will get $-x^4$ by 4 $- x$ by 3 $+ x^4$ by 4. So, from here, if you see, I can write this value, x^4 by 3 $- x^4$ by 4 $- x$ by 3 and this one can be written as that my yx will be x^4 $12 - x$ by 3.

So, this is the solution for the corresponding equation with the help of Green functions. You can solve this equation, because if you see, that I have solved this equation, y'' is equal to x^2 , with initial condition that y at 0 is 0 and y' at 1 is 0. So, you can also solve this equation with the previous method where we were solving the differential equation with constant coefficients and the right hand side function is a polynomial, so that is x^2 .

So, if you solve this one with the previous methods, then we should get the same solution as this. So, this is you can take as homework to verify whether you are getting the same solution for this one with the operator method or not. So thanks very much for this lecture, so in this lecture we have discussed that how we can develop the Green function for initial problem and the boundary value problem.

And then we also solved few examples and verified that, that if we are applying the Green function or the methods we have solved with the help of operators, then we found that the both results are coming same. So in the next lecture, we will go further and we will try to find and apply the Green function for some other problems. Thank you very much.
