Grammars
Lecture - 1
Context- Free Grammars

So, for we have learnt, what is formal definition of a language and how to represent them finitely finite representation? In that context we have called the notion called regular expression to the language. Now, there we have understood that some of the language we can represent to through regular expression and sum of them you could not. So, in this context we will introduce a better tool to represent a language finitely; the finite representation.

(Refer Slide Time: 01:10)

So, in the context we are introducing the tool called grammars as naturally one may expect to understand the language. So, again here the notion of grammar word grammar is familiar to you and you know grammars in the context in the natural languages. Now, first here we formalize the notion and then make you familiar with this formal notion so certain examples. First what is the understanding we have about grammar; that is a grammar of a language is a set of rules which are used to construct or validate sentence of the language; that is how we know grammar that is the expectation we have. Now, to

formalise we have motion; we have to look at certain general features of the grammars; that we know already from which the important features that may be captured and may be reflected the formulation of the notion of a grammar. So, when we are looking for the general grammar that means in the context of natural languages you may first look at.

(Refer Slide Time: 02:18)

Example

- Consider the English sentence
The boy ate an apple.
- How the sentence is grammatically correct?
- The Article the followed by the Noun boy form a Noun-phrase.
- The Article an followed by the Noun apple form a Noun-phrase.
- ate is a Verb.
- Choose the Sentential form
"Subject Verb Object"
- Note that Subject or Object can be a Noun-phrase.

NPTEL K. V. Krishna (IITG) Formal Languages and Automata Theory 3 / 21

So, from English let us consider the sentence the boy ate an apple; if you question that this is grammatically correct or not? Let us look at this way the article the followed by the noun boy form a noun phrase. The article an followed by the noun apple form a noun phrase; and ate is a verb and now if you choose a sentential form svo, so called subject verb of the object. Now, you can understand note that subject or object can be a noun phrase and you can validate the sentence.

(Refer Slide Time: 03:05)

Derivation of an English Sentence

This verification/derivation can be shown as below

Sentence

- ⇒ Subject Verb Object
- ⇒ Noun-phrase Verb Object
- ⇒ Article Noun Verb Object
- ⇒ The Noun Verb Object
- ⇒ The boy Verb Object
- ⇒ The boy ate Object
- ⇒ The boy ate Noun-phrase
- ⇒ The boy ate Article Noun
- ⇒ The boy ate an Noun
- ⇒ The boy ate an apple.

NPTEL K. V. Krishna (IITG) Formal Languages and Automata Theory 4 / 21

For example, you can validate the sentence or you can verification sentence the sentence will be geometrically correct in English. So, in the as I am showing here you may possibly validate that take the sentential form, take the sentence that rule subject verb object then subject you may place by noun phrase. And then the noun phrase can be an article followed my noun that rule you may use. And the article you placed by the article b and then noun by boy and then verb by ate. In case of object you are choosing noun phrase the rule and the noun phrase can be article followed by noun and the article here choosing noun and the noun apple. So, the boy an apple can be past or can be verified through English grammar in this way.

(Refer Slide Time: 04:16)

Now, 2 formulate a notion of a grammar; first let us see in this context what type of words that we have considered; the words like a, an, the, boy, book, is, this kind of word that you have encountered. The words like article, noun, verb, noun phrase; this kind of word that we have encounter. So, what is the difference between 2? If you look at the second type of words that means article noun, verb this kind of things you have to address them further. That means, we can say noun what is that noun you are going to talk about. So, you have to tell something about that further and that means this is not get terminated. So, you have to further tell something about this. Now, if we look at the first type that one; if you say an, the, boy that kind of words there is nothing further you are going to say in English. So, that way we may call them as terminals and the first one we call them as non-terminal.

(Refer Slide Time: 05:23)

So, informally when I am talking about grammars; what are the things that you have understood here is a set of non-terminal symbols have to be there, as a set of terminal symbols and set of rules. For example, noun phrase can be a article followed by noun or a subject can be noun phrase; this kind of rules we have use in the derivation. So, a set of rules that you are requiring. Now a distinguished non-terminal symbol; that means for any sentence what is the main target in a grammar? So, you are going to validate sentences or you are going to derive a sentence through the rules the existing in the grammar. So, essentially target in to derive a sentence; so a distinguishable non terminal symbol that you are indicating as a sentence. So, that is to derive; any sentence from there.

(Refer Slide Time: 06:20)

Formal Definition

Formally, a grammar is a quadruple

$$G = (N, \Sigma, P, S)$$

where

- N is a finite set of nonterminals,
- Σ is a finite set of terminals,
- $S \in N$ is the start symbol, and
- P is a finite subset of $N \times V^*$ called the set of production rules. Here, $V = N \cup \Sigma$.

NPTEL K. V. Krishna (IITC) Formal Languages and Automata Theory 7 / 21

Now, formally we will introduce the combinatorial system; as a quadruple I am writing here $G(N, \Sigma, P, S)$; where N is a finite set we may call them as non-terminal symbols; Σ is a finite set again, a terminals again and S belongs to N ; that means this is a non-terminal symbol; that we call them start symbol; this is a representing phrase sentence. And, P is finite subset of N cross V^* called the set of production rules. What are the rules we are here having there are called production rules and here V equals to N union Σ .

(Refer Slide Time: 07:11)

$N \times V^*$

(A, α)

for $A \in N$
and $\alpha \in V^*$

$A \rightarrow \alpha$

NPTEL 1 / 1

Now, let us look at $N \times V^*$ here the elements are of the form $N \times V^*$; a non-terminal symbol and a string of V square. That means, here α is a mix of terminals and non-terminal and string over mix of terminals and; this A is a non-terminal symbol. So, the rules are essential phrase which are of the form $A \alpha$. Now, for convince since we are calling it a rule we write $A \alpha$ in this way; and called A can be α . Now, before going to talk about the sentence that are to be validated through a grammar and our sentence which can be derived or generated are using a grammar; we require certain concept.

(Refer Slide Time: 08:29)

Yields in One Step

We require the following concepts:

Let $G = (N, \Sigma, P, S)$ be a grammar with $V = N \cup \Sigma$.

- We define a binary relation $\Rightarrow$ on V^* by

$$\alpha \Rightarrow \beta \text{ if and only if } \alpha = \alpha_1 A \alpha_2, \beta = \alpha_1 \gamma \alpha_2$$

and $A \rightarrow \gamma \in P,$

for all $\alpha, \beta \in V^*.$
- The relation $\Rightarrow$ is called *one step relation on G* .
If $\alpha \Rightarrow \beta$, then we call α *yields β in one step in G* .

NPTEL K. V. Krishna (IITG) Formal Languages and Automata Theory 8 / 21

So, let us first look at those concepts. Let us consider a grammar g that is a with V is N union Σ ; first we define a binary relation that is represented here with a implies symbol; that is with subscript g on V star. That means, we are depending on a binary on V star; V star again I repeat this the strings with mix terminals and non-terminal.

How we are defining this relation α related to β using this relation if and only if α is of the form $\alpha_1 A \alpha_2$ β is the form $\alpha_1 \gamma \alpha_2$. Here, the relation between α and β that for a non-terminal symbol A that we are replacing by the γ . That means, it is replaced by a production rule; then we say that they are related. So, that means here $A \rightarrow \gamma$ is a production rule in this grammar; for all α in β in V star. Now, the relation this is called one step relation on g . Because

applying the 1 rule from alpha we get beta in 1 step. So, this is called one step relation on g. And, if alpha gives beta in one step then we call alpha yields beta in one step in g.

(Refer Slide Time: 09:59)

Derivation

- $\xrightarrow{*}_G$ is the reflexive-transitive closure of $\xrightarrow{1}_G$. That is, for $\alpha, \beta \in V^*$,

$$\alpha \xrightarrow{*}_G \beta$$

if and only if $\exists n \geq 0$ and $\alpha_0, \alpha_1, \dots, \alpha_n \in V^*$ such that

$$\alpha = \alpha_0 \xrightarrow{1}_G \alpha_1 \xrightarrow{1}_G \dots \xrightarrow{1}_G \alpha_{n-1} \xrightarrow{1}_G \alpha_n = \beta.$$

- For $\alpha, \beta \in V^*$, if $\alpha \xrightarrow{*}_G \beta$, then we say
 - β is derived from α or
 - α derives β .

Further, $\alpha \xrightarrow{*}_G \beta$ is called as a derivation in G .

NPTEL K. V. Krishna (IITG) Formal Languages and Automata Theory 9 / 21

Now, another notation here; this relation with super script star if we write; that is reflexive transitive closure over the one step relation that we have defined. That means, if you take any 2 strings alpha, beta in V star; we say alpha related beta with respect to this reflexive transitive closure of one step relation if and only through finitely ((Refer Time: 10:33)) these 2 are related. That means, they exist number n greater then equals to 0 and strings alpha naught alpha 1 and so on alpha n star such that this alpha naught is alpha and you can get in 1 step alpha 1 from alpha naught and so on. And, alpha n you will get it from alpha n minus 1 that alpha n is beta.

So, that means essentially this reflexive transitive closure the relation reflexive transitive closure is by through finitely steps of 1 step relation; you are relating 2 strings. Now, for alpha beta; if this two are related to be reflexive transitive closure relation that means through finitely meaning steps you can get beta form alpha. Then, we say beta is derived from alpha or we can say alpha derives beta; further this expression alpha gives infinitely beta is called derivation in g.

(Refer Slide Time: 11:42)

Derivation (Cont...)

- If $\alpha = \alpha_0 \xRightarrow{G} \alpha_1 \xRightarrow{G} \dots \xRightarrow{G} \alpha_{n-1} \xRightarrow{G} \alpha_n = \beta$ is a derivation, then the length of the derivation is n and it may be written as $\alpha \xRightarrow{G}^n \beta$.
- In a given context, if we deal with only one grammar G , then we may simply write $\Rightarrow$, instead of $\xRightarrow{G}$.
- If $\alpha \xRightarrow{G}^n \beta$ is a derivation, then we say β is the yield of the derivation.

NPTEL K. V. Krishna (IITG) Formal Languages and Automata Theory 18 / 21

The notion of derivation is reduced here formally. Now, if you consider a derivation that is α gives α_1 first step, and α_1 is second step and so on α_n that is β . If is derivation then the number of steps in this will be counted and say that it is length of derivation; we can see that here n steps and thus we called length of the derivation is n . And, in which case one by denote by taking the n in the subscript super script of the relation. Now, let us on the convention very time we are using the subscription G in give a context if you are handling with only one grammar G . Then, you may simply use the symbol $\Rightarrow$ instead of $\xRightarrow{G}$. Now, if you consider derivation α if gives β infinitely in many steps; we also called β is an yield of the derivation.

(Refer Slide Time: 12:46)

The image is a screenshot of a presentation slide titled "Language of a Grammar". The slide has a yellow background with a blue header. It contains three bullet points and a mathematical definition. The first bullet point states that a string $\alpha \in V^*$ is a sentential form in G if it can be derived from the start symbol S of G , denoted as $S \xRightarrow{*} \alpha$. The second bullet point states that if $\alpha \in \Sigma^*$, then the sentential form α is known as a sentence, and we say α is generated by G . The third bullet point states that the language generated by G , denoted by $L(G)$, is the set of all sentences generated by G . Below the bullet points, the formal definition of $L(G)$ is given as $L(G) = \{x \in \Sigma^* \mid S \xRightarrow{*} x\}$. The slide is part of an NPTEL presentation by K. V. Krishna (IITG) on Formal Languages and Automata Theory, slide 11 of 21.

Language of a Grammar

- A string $\alpha \in V^*$ is said to be a sentential form in G , if α can be derived from the start symbol S of G . That is, $S \xRightarrow{*} \alpha$.
- In particular, if $\alpha \in \Sigma^*$, then the sentential form α is known as a sentence. In which case, we say α is generated by G .
- The language generated by G , denoted by $L(G)$, is the set of all sentences generated by G . That is,

$$L(G) = \{x \in \Sigma^* \mid S \xRightarrow{*} x\}.$$

NPTEL K. V. Krishna (IITG) Formal Languages and Automata Theory 11 / 21

Now, if we take a string $\alpha \in V^*$ we call this is a sentential form in G ; if can be derived from the start symbol S ; in the grammar and consideration we have start symbol S from which we can derive this string α . Then, we say this is sentential form. In particular if this α only with terminal symbols. That means, if it is an element of Σ^* then sentential form is called sentence; in this case α is generated by G . And, now we formally depending the notion of generated by the grammar G ; the language generated by G denoted by $L(G)$ is the set of all sentences generated by G ; that is $L(G)$ set of all x and the Σ^* ; those terminal strings which can derived from in the start symbol.

(Refer Slide Time: 13:50)

Context-free Grammar

- $A \rightarrow \alpha$ is the form of an arbitrary rule.
- If $X_1 \cdots X_k A X_{k+1} \cdots X_n$ is a sentential form, then $X_1 \cdots X_k A X_{k+1} \cdots X_n \Rightarrow X_1 \cdots X_k \alpha X_{k+1} \cdots X_n$
- This replacement is independent of the neighboring symbols of A .
- One may call A is within the context of X_i 's and hence the rules $A \rightarrow \alpha$ are said to be of context-free type.
- Thus, the type of grammar that is defined here is known as context-free grammar, simply CFG.

NPTEL K. V. Krishna (IITC) Formal Languages and Automata Theory 12 / 21

Now, if you look at an arbitrary rule in the grammar that we have defined; it is the form $A \rightarrow \alpha$; for A goes to α . If the sentential form that means this string X_1 and so on $X_k A X_{k+1}$ and so on X_n ; if this sentential form that means this is derived from the start symbol. And, as this $A \rightarrow \alpha$ is a rule; by applying this rule in the sentential form you can get a next step which is of the form X_1, X_2 and so on $X_k \alpha X_{k+1}$ and so on X_n . Now, in the sentential form the replacement is independent of the neighboring symbol of A , because of the production rule is of the form $A \rightarrow \alpha$ wherever A is occurring you can substitute A by α to get a sentential form resulting like this.

Now, as the replacement independent of A ; one may call A is within the here you observe first that the non-terminal symbol A is within the context of X_i 's the neighboring the symbols X_1, X_k the neighboring symbols of A are say for example X_k, X_{k-1}, X_{k+1} or if you go little more X_{k-1}, X_k, X_{k+1} ; these are the neighboring symbols of A . Now, one may call A is within the context X_i 's depending on the neighboring symbols that you are considering. Now, hence the rule $A \rightarrow \alpha$ is said to be of context free type; the reason why when you substituting A by α we are not worried about the neighboring symbols of A . And, this rule is a context free type and the type of grammar the defines of now here we called the context grammar for simply CFG; context free grammar.

(Refer Slide Time: 16:04)

Context-free Language

A language L is said to be context-free if there is a context-free grammar G that generates L . That is

$$L(G) = L.$$

NPTEL K. V. Krishna (IITG) Formal Languages and Automata Theory 13 / 21

Now, the notion of context free language is as follows; a language L is said to be context free if there is a context free grammar G that generates L ; that is $L(G)$ equal to L ; the language generated by G should be equal to L .

(Refer Slide Time: 16:25)

Example-1

Consider the CFG $G = (N, \Sigma, P, S)$, where

- $N = \{S\}$
- $\Sigma = \{a, b\}$
- $P = \{S \rightarrow ab, S \rightarrow bb, S \rightarrow aba, S \rightarrow aab\}$

Derivations in G :

- $S \Rightarrow ab$
- $S \Rightarrow bb$
- $S \Rightarrow aba$
- $S \Rightarrow aab$

NPTEL K. V. Krishna (IITG) Formal Languages and Automata Theory 14 / 21

Now, look at the certain examples to understand the notion defined here. Consider the CFG $G(N, \Sigma, P, S)$; where N is single terminal S , Σ is set of a, b . And, the production rules we are considering S gives ab , S gives bb , S gives aba , S gives aab finitely many rules. And, left side only one non-terminal symbol is only one non-terminal

symbol is there and right side mix of terminals and non-terminal are allowed. Here, we are considering only terminal symbols. For example, here a b and b b here and a b a here and a a b here; finitely many rules are under consideration. Now, what let us look at the certain example derivation in G; S derives string a b in one step by using the rule S gives a b. Let us look at another derivation S derives a b by using the second rule S gives you can derive the terminal string bb in one step again. Similarly, S derives a b a you can apply the third rule, we can one step we can that the terminal string; also S derives a a b and can we have some other derivation in this grammar; there is only non-terminal symbol you will start there is only one non-terminal symbol.

(Refer Slide Time: 18:13)

Example-1

Consider the CFG $G = (N, \Sigma, P, S)$, where

- $N = \{S\}$
- $\Sigma = \{a, b\}$
- $P = \{S \rightarrow ab, S \rightarrow bb, S \rightarrow aba, S \rightarrow aab\}$

Derivations in G:

- $S \Rightarrow ab$
- $S \Rightarrow bb$
- $S \Rightarrow aba$
- $S \Rightarrow aab$

Hence, the language generated by G,

$$L(G) = \{ab, bb, aba, aab\}.$$

The slide is part of an NPTEL presentation by K. V. Krishna (IITC) on Formal Languages and Automata Theory, slide 14 of 21.

You will have a non terminal symbol A and you have to apply one rule to the next sentential form in a derivation under consideration. The possibility understand here you may apply the first rule and second rule, third rule or fourth rule whatever you are applying for example, apply first rule S gives a b. Then, after that to continue this derivation you require non-terminal symbol in this and there is no non-terminal symbol here. And, thus you cannot continue this derivation by starting with first rule; if you want to the derivation more in one step. For example, if we consider the second rule S gives bb we have similar situation because right side immediately we got at terminal string. Similarly, third rule or fourth rule because every rule here essentially is of the form x goes to say some x; where x is sigma star terminal string; I do not have A option to continue to derivation further. And, thus here you can understand that any derivation in

this grammar is essentially have only 1 step here; in 1 step here you can generate a b or b b, a b a or a a b; there only 4 strings that we can derived here.

Thus, you can understand that the language generated by this grammar is continue precisely 4 strings a a, b b, a b a, a a b. And, this 4 strings can be generated to understand that this set is equal to $L(G)$ and every string in this set can be generated by as G . So, derivations and these are only strings that can be generated in this grammar; thus the language generated by G is this.

(Refer Slide Time: 20:11)

Example-2

Suppose L is a finite language over an alphabet Σ , say

$$L = \{x_1, x_2, \dots, x_n\}.$$

Then consider the finite set

$$P = \{S \rightarrow x_1 x_2 \mid \dots \mid x_n\}.$$

NPTEL K. V. Krishna (IITG) Formal Languages and Automata Theory 15 / 21

Let me consider another example by extending this motion whatever the examples here we have define here. In the previous example once again here we consider the 4 strings and this is the grammar we have define. Now, if you take any finite languages you have finitely strings in that so L equal to x_1, x_2 and so on x_n ; finitely strings are there. Now, if we consider finite sets P contain S gives x_1 here we are introducing the notation are symbol x_2, x_3 and so on x_n .

(Refer Slide Time: 21:03)

$$S \Rightarrow \underline{ab}$$

$$S \rightarrow x$$

$$x \in \Sigma$$

$$\underline{S} \rightarrow ab$$

$$\underline{S} \rightarrow bb$$

$$S \rightarrow ab \mid bb$$

$$\{x_1, x_2, \dots, x_n\}$$

$$S \rightarrow x_1 \mid x_2 \mid \dots \mid x_n$$

So, here the notation what we are introducing here is in the earlier case S gives to a b is 1 production rule, S goes to $b b$ 1 production rule; that the notation we adopt instead writing 2 rules separately; when the non-terminal symbol left side when both having S we may write it as S goes to $a b$ or $b b$; this is how we read. And, in the present context when we have finitely strings X_1, X_2 and so on X_n the finite language; by considering the production rules s gives $X_1, r X_2$ and so on $r X_n$ where n number of rules. By considering we can generate the language X_1, X_2 and X_n .

(Refer Slide Time: 22:07)

$$P = \{S \rightarrow x_1 \mid x_2 \mid \dots \mid x_n\}$$

$$G = (N, \Sigma, P, S)$$

$$N = \{S\}$$

$$\Sigma$$

Now, here one more notation that we are adopting namely; if we are giving just production rules in this context S goes to $X_1, X_2, \dots, X_n$; we are not giving what is that quadruple for the grammar; we may not specially specify whatever the non-terminal symbol that is occurring in this set that you can considering in an. For example, if we here only non-terminal symbol and sigma whatever the terminals under consideration and production rules are defined and the start symbol S if non-terminal from non terminal. So, using this notation just by stating the set of production rules; one can always write quadruple G . And, thus using that notation I am simply stating note that the $C F G$; single terminal sigma, P, S generates the language L .

(Refer Slide Time: 23:21)

Example-3

Consider a CFG G with precisely the following production rules.

- 1 $S \rightarrow 0S$
- 2 $S \rightarrow 1S$
- 3 $S \rightarrow \epsilon$

We now observe that G generates $\{0, 1\}^*$.
Clearly, $L(G) \subseteq \Sigma^*$.
On the other hand, let $x \in \Sigma^*$. If $x = \epsilon$,

NPTEL K. V. Krishna (IITC) Formal Languages and Automata Theory 16 / 21

Now, let me do one more example. Consider the $C F G$; G with precisely the following production rule; 1 S gives $0 S$; 2 S gives $1 S$; 3 S can be epsilon. Now, every that the grammar G generate $0, 1$ star; here I am not stating the quadruple; only the production rule are stated. If one is intersect to right it is easy.

(Refer Slide Time: 24:16)

The image shows a digital whiteboard with handwritten text. At the top, the grammar is defined as $G = (\{S\}, \{0,1\}, P, S)$. Below this, the terminal symbols are listed as $\Sigma = \{0,1\}^*$. Two sets of derivations are shown. The first set shows $S \Rightarrow 0S \Rightarrow 0\epsilon = 0$ and $S \Rightarrow 1S \Rightarrow 1\epsilon = 1$. The second set shows $S \Rightarrow 0S \Rightarrow 00S \Rightarrow 00\epsilon = 00$. The whiteboard has a toolbar at the top and a taskbar at the bottom.

$$G = (\{S\}, \{0,1\}, P, S)$$

$$\Sigma = \{0,1\}^*$$

$$S \Rightarrow 0S$$

$$\Rightarrow 0\epsilon = 0$$

$$S \Rightarrow 1S$$

$$\Rightarrow 1\epsilon = 1$$

$$S \Rightarrow 0S$$

$$\Rightarrow 00S$$

$$\Rightarrow 00\epsilon = 00$$

In this context you have again only one non-terminal symbol; terminal symbols are 0 and 1; the production rules are stated and the start symbol S you consider. And, thus the quadruple G is this in the present context. And, if I call the grammar G we observe that grammar G generates Σ^* ; here Σ is 0, 1. So, all the strings or Σ can be generated in this, using this. To prove this first what are the possible strings that we can generate using these rules; that we have to evaluate. First, can we generate some strings through these rules that we have understood.

For example, using the first rule $S \Rightarrow 0S$ one can clearly generate in one step (Refer Time: 25:27) ϵ or if you consider the first rule we get $S \Rightarrow 0S$ in 1 step. And, if you use the third rule then 0ϵ that equals to 0. So, the string 0 can be generated using this grammar; that means we are generating certain strings through these rules. Similarly, by using the second rule one can derive $1S$ and applying the third rule we get simply 1. So, 0 can be generated, 1 can be generated; if you want 0, 0 can be generated consider the first rule once we can derive like this. And, then we apply once more; the first rule we generate string 0, 0 S .

Now, if you apply the third rule $0, 0\epsilon$ the string ϵ that is essentially 0, 0. So, 0, 0 can be derived; and understand here the 3 rules; $S \Rightarrow 1S$ and $S \Rightarrow \epsilon$ you are deriving certain strings. And, whatever the terminals that we are deriving they are the whole set 0, 1. And, thus first we understand that every string generated this

grammar the $L(G)$ is a subset of Σ^* . Because Σ^* is a set up all strings are 0, 1. And, therefore $L(G)$ is a subset of Σ^* ; conversely we have to understand that every string of Σ^* can be derived in the grammar; taking arbitrary string x and Σ^* .

(Refer Slide Time: 27:40)

Example-3 Cont...

Otherwise, let $x = a_1 a_2 \dots a_n$, where $a_i = 0$ or $1 \forall i$.
 Now x can be derived in G as follows.

$$\begin{aligned}
 S &\Rightarrow a_1 S && \text{(if } a_1 = 0, \text{ then by rule 1;} \\
 &\Rightarrow a_1 a_2 S && \text{else by rule 2)} \\
 &\vdots && \text{(as above)} \\
 &\Rightarrow a_1 a_2 \dots a_n S && \text{(as above)} \\
 &\Rightarrow a_1 a_2 \dots a_n \epsilon && \text{(by rule 3)} \\
 &= x.
 \end{aligned}$$

Hence, $x \in L(G)$. Thus, $L(G) = \Sigma_i^*$

NPTEL K. V. Krishna (IITG) Formal Languages and Automata Theory 17 / 21

If is empty string using third rule in one step you can derive it if you write it as here a 1, a 2 and so on a n; where a i is 0 or 1; some n number of string if you consider. Now, this a 1, a 2, a n we can derived as shown below; this a 1 can be 0 or 1; if it is 0 then apply rule 1 to get that S gives a 1 S; if it is 1 then you can apply rule 2 to get 1 S here. Similarly, to derive the a to n either it is 0 or 1 I will discussed here; if a 2 is 0 apply rule 1 to get a 2 S; if a 2 is 1 apply rule 2 to get a 1 a 2 S and continue this to get a 1 a 2 a n S. And, at the end applied rule 3 and nullify the non-terminal symbol here to get a 1 a 2 a n that it what is x.

So, any string x a 1 a 2 can be derived in n number of steps you are getting a 1 a 2; in the first step a n, in the second step get a 1 a 2 and following S and n number of steps, you are getting a 1 a 2 an S and n plus 1 step you can nullify S by substituting n 2 string. And, thus you can getting a 1 a 2 an this n string that we are deriving here n plus 1 step; the length of the derivation here n plus 1 and n; n means string can be derived here exactly n plus 1 step. And, thus you understand that any string or sigma star can be

derive to the grammar; hence x is in $L(G)$. So, we have got the include $L(G)$ is Σ^* .

(Refer Slide Time: 29:53)

Example-4

The language $\emptyset$ (over any alphabet Σ) can be generated by a CFG.

Method-I. Consider the CFG $\mathcal{G} = (\{S\}, \Sigma, P, S)$, where $P = \emptyset$.

Method-II. Consider a CFG $\mathcal{G}$ in which each production rule has some nonterminal symbol on its right hand side.

Note that $L(\mathcal{G}) = \{\epsilon\}$.

NPTEL K. V. Krishna (IITG) Formal Languages and Automata Theory 18 / 21

Let us consider one more example; if you consider the languages empty; the languages are empty over any alphabet consider; we can say can be generated by a CFG. How do give the grammar? I give you 1 method here; if you consider the grammar single sigma P S; where P is empty.

(Refer Slide Time: 30:36)

$$(P) \subseteq N \times V^*$$

$$\parallel$$

$$\emptyset \quad V = \Sigma \cup N$$

$$P = \{ A_1 \rightarrow \alpha_1, A_2 \rightarrow \alpha_2, \dots, A_k \rightarrow \alpha_k \}$$

$$S \Rightarrow \alpha_i$$

$$\Rightarrow \beta$$

$$\alpha_i = A_j \alpha_i$$

$$\beta = \alpha_j \alpha_i$$

NPTEL 5 / 5

The set of production rules we did not put any restriction we simply said that this production rules is a subset of $N \times V^*$; where V is $\Sigma \cup N$ there is no restriction on this; it can be empty set also V subset of this. So, if you choose the production rules to be empty then we are not going to derive we will not able to derive any string in this grammar. And, thus the language generated by grammar G define here is empty or if you want some production here we can follow this method 2; if you consider the grammar in which each production rule has some non terminal symbols on its right hand side; some non-terminal symbols are right hand side on each production rule. So, what is the situation that you get? That means, say finitely production rules that you would have; let me take for example, A_1 goes to α_1 , A_2 goes to α_2 and so on; some finitely rules A_k goes to α_k finitely.

And, the assumption here is each α_i has some non-terminal symbol on its right hand side. Now, you start the derivation start you may start with derivation; what is the symbol S ? If start symbol equal to i here you may get that α_i . And, then in α_i what is the non-terminal symbol is appearing and we will continue to sum a j you substitute that. And, you are getting some string β where β is obtained from α_i ;by substituting the non-terminal symbol that you have. Say for example, you have a j in α_i that means in α_i is of the form some $\alpha_1 \alpha_2$ and by substituting the what are the β we have got β is α_1 a j substituted by α_j and α_2 .

And, clearly as for our assumption let me call it as instead of writing $\alpha_1 \alpha_2$ which as used here already; let me call it as α dash say α double dash. So, what we got β is α dash α_j α double dash and in β you can clearly that there is non-terminal symbol, because α_j has non-terminal symbol. Now, they may non-terminal symbol α dash and α double dash also. Now, you see the non terminal α_j there is no non terminal symbol.

For example, if you choose and substitute and if you continue like this; every time will observing the there is one non-terminal symbol in each step that we are continuing to. So, you are continuing to non-terminal symbol always in each step and thus any derivations that you start with; it will never terminate. And, thus no terminal string can be generated using the grammar. And, thus this CFG with this property you will derived only one set. So, thus we have understand in either case, if you follow method 1 and if you follow method 2 the grammar and consideration generates the language empty.

(Refer Slide Time: 34:43)

Let us look at some more.

(Refer Slide Time: 34:56)

So, for what I have considered here; I have gave some grammar and understood that language is generated by those grammars. Now, in the previous case I have considered empty language and given an appropriate grammar to generate. Now, let us consider this; because what are the examples that I am starting with they are all known to you; that they can be represented by regular expressions. Because the finite set with 4 strings you know the regular expression of that. And, finitely ((Refer Time: 35:36)) that is the

regular language, sigma star that is the regular language and empty this is the regular languages. Now, one more here in the consideration you know this is also a regular language. And, here we are defining a contextual grammar for the languages; we are also observing that we languages are context free. So, a typical string in this having k a s; it can be empty string 2 a s, 3 s and so on a power k.

Now, for this purpose if you consider anyway you required non-terminal symbol as a start symbol; let me called as I said S; I have to derived a so let me take a and I should be able to further continue. So, because I am going to produce only a. So, if I consider the rule S goes to a s; I can have this kind of situation S gives a s and using the same rule I can derive 2 a a s. And, again apply the same rule we can get a a a s; because this S substitute by a s; using this rule. And, if continue this we can produce n number of a s after n step; if you terminate this by substituting S goes to epsilon the empty string. Then, you can terminate this that is what is a power n. But you observe this by considering by this 2 rules S goes to a s; S can be epsilon; we can clearly thus in n plus 1 step to generate a power n.

(Refer Slide Time: 38: 14)

$$\begin{aligned}
 & \underline{G} \quad P = \{ \underline{S \rightarrow aS} \mid \epsilon \} \\
 & \text{Claim } L(G) = \{ a^k \mid k \geq 0 \} \\
 & \Sigma = \{ a \} \quad \Sigma^* = \{ a^k \mid k \geq 0 \} \\
 & L(G) \subseteq \Sigma^* \\
 & \underline{L(G) = \Sigma^*}
 \end{aligned}$$

Thus, if I consider the grammar with this production rule; that is I am going to write the quadruple as a I said you can consider this non-terminal symbol and terminal set in singleton set. And, production rules are stated here; so just stating this we are stating the grammar. So, let G be the grammar with this following production rules; the claim now

is the language generated by this grammar is and as you understand here that; what are the strings are derive $L(G)$? That first we have look at and you have to look at sigma a single term a under consideration; what is sigma star? This is precisely a power k ; k greater than equal to 0 and one can observe that whatever the strings that you are generating in this grammar is a subset of sigma star as discussed earlier. Now, to show that any string of sigma star can be generated; we can look at the previous example and quickly understand that we have consider by taking sigma to be consideration. So, thus you are understanding that $L(G)$ equal to sigma star.

So, what is the point here is we are treating considering sigma to be single term a; as a special case of previously example. And, thus you understand that a power k greater than equal to 0; this is called to context free. Because if you considering sigma to be single term a this is what is to be sigma star.

(Refer Slide Time: 40:52)

The image shows a handwritten derivation of a grammar G and its language $L(G)$. At the top, the language is defined as $L = \{ a^n b^n \mid n \geq 0 \}$ with a checkmark. Below this, a list of strings is shown: ϵ , ab , $aabb$, $aaabbb$, and so on. To the right, the grammar rules are given: $S \rightarrow aSb$ and $S \rightarrow \epsilon$. A derivation is shown starting from S , applying $S \rightarrow aSb$ three times to get $aaabbb$. At the bottom, the grammar is formally defined as $G: P = \{ S \rightarrow aSb \mid \epsilon \}$ and $L(G) = L$ is stated, with a note "(Exercise)" and a checkmark.

Let me discuss one more example; this you have not seen earlier; the language a power n b power n such that n greater than equals to 0. So, how does atypical string look like in this language; epsilon by taking the n equal to 0; you can have a, b here by taking n equal to 1; you can have a a b b and a a a b b b and so on; these are this kind of string are there in this language strings. Now, look at the pattern of strings here; corresponding to each a here you have a b; in this you see there are 2 a here 2 b, 3 a and 3 b. Let me look at the corresponds like this; this a is corresponding to this b. So, here let me correspondence

like this. And, similarly here this a is corresponding to this b and second a is corresponding to this second from the right side. Suppose, if you give this correspondence then you can think of the production rule; that can generate this language. Because in each step we have to remember that a and b are having the this correspondence. So, if I write the production rules like this and this production rule if you keep applying in each step you can generate left side n number of S. And, similarly right side n number of the strings. Let us look at the derivation of apply this rule to get a s b I have written only one rule. So, you have the choice of applying same look that 2 a s sorry here it will be b; 2 b are generated. Now, if you apply this rule once again what do you get a a S b b. Now, you understand how to terminate this 2 derivations by choosing the rule S goes to epsilon.

Now, this 2 strings sorry this 2 rules can generate any string of this language and conversely; any string of this language let me call L can be derived through this 2 rule. Now, if you consider the grammar with production rules as define here S goes to a S b or epsilon; the grammar with this production rule. You can observe that the language generated by the grammar G is L; a power n, b power n such that greater than equals to 0; you can take this as exercise a string. That means, what you have to show? A string generated in G is on the form a power m b power m that is in L. And, if you take any string in L; that means a string of the form a power m, b power m can be generated through G. So, prove this as an exercise? Let me disused some more examples.

(Refer Slide Time: 45:06)

Handwritten notes on a digital whiteboard (NPTEL logo visible) defining palindromes over the alphabet $\Sigma = \{a, b\}$.

The set of all palindromes over Σ .

$$L = \{ x \in \Sigma^* \mid x = x^R \}$$

$\Sigma = \{a, b\}$

$x \in \Sigma^*$

$x = a_1 a_2 \dots a_n$

Exercise

Diagram illustrating the structure of a palindrome x of length n :

- For even length $n = 2k$, the string is $a_1 a_2 \dots a_k b_k \dots b_1$, where the first k characters are mirrored in reverse order.
- For odd length $n = 2k+1$, the string is $a_1 a_2 \dots a_k a_{k+1} b_k \dots b_1$, where the first k characters are mirrored in reverse order around a central character a_{k+1} .

Let me disused some more examples power any alphabet if you consider the language; x power R ; what is the language? All the strings in Σ^* which is equals to its reversal. That means, the set of all palindrome; if consider this the previous example; the concept of example can be used to define a grammar for this language; for simplicity let me consider Σ to be $\{a, b\}$; from that you can understand to give a grammar for the arbitrary alphabet Σ . What is the situation here; if you take any string x from the language L here; let me call L for this language; a string x would of the form a_1, a_2, a_3 and so on a_n . There are two cases; one there may be even number of symbols here this is a even line, there may be of hard line. If it is that even line what do you have a_1 , it is of the form a_1, a_2 and so on a_k , let me write.

And then there after a_k plus 1 say there are b_1, b_2, b_k ((Refer Time: 47:19)) it is of length $2k$; n is equal to length $2k$. And, if it is of odd length I may write it as a_1, a_2, a_k, a_{k+1} . And, then let me write the b_1, b_2, b_k let us write like this; this even length string and this is odd length string. Here, n is of the form $2k + 1$; this is the line. Now, look since it is a palindrome the symbol a_1 should be equal to this b_k ; the a_2 should be equal to b_{k-1} and so on; this a_k should be equal to b_1 . In case of odd length the same situation on either side and a_{k+1} can be anything between a and b . Then, you can think off the production rules for the Σ set of a, b and give a grammar we generates palindromes; try this as an exercise. And, hence you can extend this for any arbitrary alphabet Σ .
