Contour Integration

(Refer Slide Time: 00:12)

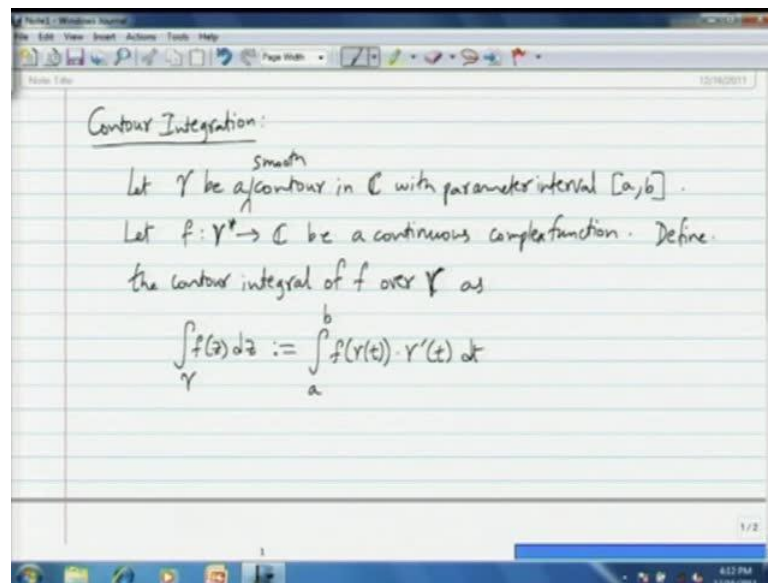

In this lecture

- ▶ Definition of contour integration and some properties.
- ▶ Contour integration is independent of parametrization of the contour.
- ▶ Fundamental theorem of calculus for complex functions.

Hello viewers, we will discuss contour integration in the session. So, last time we defined what a contour is. It is a join of piecewise smooth curves over some parameter interval, and we are going to use those contours to define a line integral of some sort for complex valued functions. So, here is contour integration.

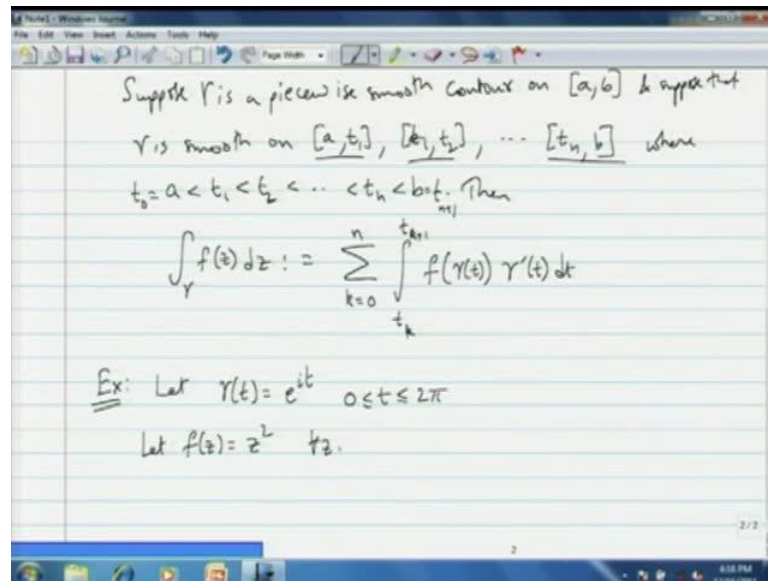

(Refer Slide Time: 00:40)

So, let γ be a contour in \mathbb{C} , with, in \mathbb{C} , this is the complex plane \mathbb{C} with a parameter interval a, b ; and let f from γ^* , remember that is the range of, the range set of the contour γ . So, f from γ^* to \mathbb{C} be a continuous complex function. So then define so the symbol, I will call this the contour integral of f over γ as, well this is the notation the contour integration of f over γ , is equal to the integration over this interval a, b of f of γ of t times γ prime of t dt . The right hand side here is actually an integral of the sort we have seen in the last session, where f of γ of t times γ prime of t is essentially a complex valued function, in the, with a real parameter t . We have integrated such functions in the last session.

So the right hand side integral, in the right hand side integral γ prime may not be defined at all places, so we will assume for this definition that γ is this smooth contour. Please allow me to make the change at γ be a smooth contour. If γ is not smooth all over, if it is piecewise smooth, like we have in a general case, then we would define this integral to be summation over specific intervals and we break this interval a, b into intervals where you know γ is smooth.

(Refer Slide Time: 03:57)

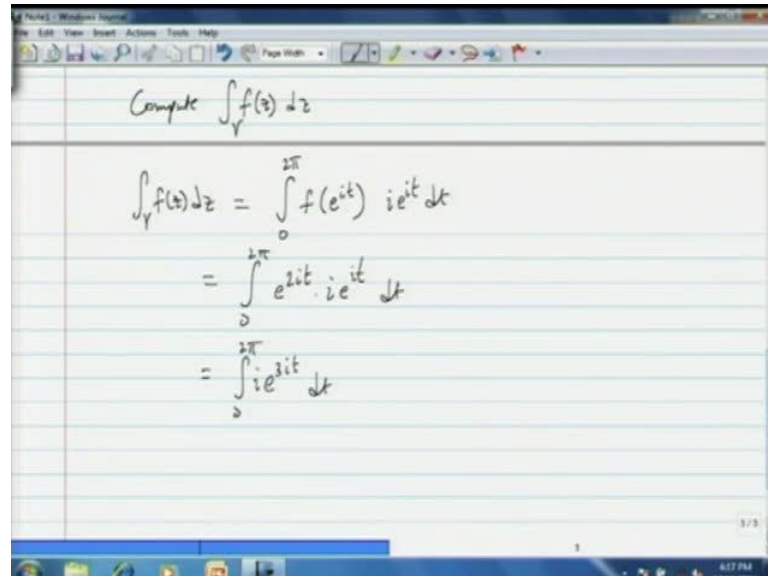

So what I mean by that is, suppose gamma is a piecewise smooth contour with the parameter interval a b, and suppose that there are n points. So, suppose that gamma is smooth on a t 1 comma t 1 t 2 etcetera t n comma b, where these points are strictly less than t1 strictly less than t 2, t n strictly less than b. So, this is how a piecewise smooth contour will look like; it's smooth on pieces like that, pieces of this interval. Then, in this case define this integration, this contour integration f over gamma is defined as the summation, well I have written this yeah, so I will write t 0 to be a and t n plus 1 to be b for convenience.

So, then I can write summation k equals 0 to n plus 1 of the integration from t k. This summation will run only until n. t k to t k plus 1 of f of gamma of t, gamma prime of t dt. Now, we do not have a problem because gamma prime is defined on all of these intervals, it is piecewise smooth so on each of these intervals gamma prime is smooth or gamma is smooth rather.

So, we can define the contour integration in a modified fashion like this for piecewise smooth contours. So let us see some examples. Let us see how to calculate contour integration, in some cases. So here is the first example. Let gamma of t be the curve, be the contour e power i t, 0 less than or equal to t less than or equal to 2 Pi. So this is the unit circle parameterised in that fashion, in the standard fashion, and let f of Z equals Z squared, this is for all z. So, in particular this function is continuous on the range of the

contour namely the unit circle, this is actually analytic function all over \mathbb{C} . It is an entire function, so it is definitely continuous over this contour.

(Refer Slide Time: 07:36)

The image shows a digital notepad with the following handwritten text:

$$\text{Compute } \int_{\gamma} f(z) dz$$
$$\int_{\gamma} f(z) dz = \int_0^{2\pi} f(e^{it}) i e^{it} dt$$
$$= \int_0^{2\pi} e^{2it} \cdot i e^{it} dt$$
$$= \int_0^{2\pi} i e^{3it} dt$$

So we can compute the contour integration of f over the given contour. So, you can compute this. This by definition is the integration over this interval parametric interval 0 to 2π of f of e power $i t$ and γ' is $i e$ power $i t$, the differentiation of e power $i t$ is $i e$ power $i t$ and then we have dt . So, this gives us, well, f of e power $i t$, f is f of Z is Z squared. So, f of e power $i t$ is e power $i t$ squared, which is e power $2 i t$ times $i e$ power $i t dt$.

(Refer Slide Time: 08:48)

$$\begin{aligned}\int_{\gamma} f(z) dz &= \int_0^{2\pi} f(e^{it}) i e^{it} dt \\ &= \int_0^{2\pi} e^{3it} \cdot i e^{it} dt \\ &= \int_0^{2\pi} i e^{3it} dt = \int_0^{2\pi} i(\cos 3t + i \sin 3t) dt \\ &= \int_0^{2\pi} (-\sin 3t + i \cos 3t) dt = \int_0^{2\pi} (-\sin 3t) dt + i \int_0^{2\pi} \cos 3t dt \\ &= 0\end{aligned}$$

So, we get integration from 0 to 2 Pi of i e raise to 3i t dt, which I am going to write as integration from 0 to 2 Pi of i times Cos 3t plus i Sin 3t dt and multiply the i you get integration from 0 to 2 Pi of minus Sin 3t plus i times Cosine 3t dt. Now the integrand is a real parameter function and its complex value and we have seen how to integrate such a function, separate it into, it is integrated by separating it into the real and imaginary part. So you get integration from 0 to 2 Pi of minus Sin 3t dt plus i times integration from 0 to 2 Pi of Cos 3t dt, which is clearly 0. So, it is how we compute these integrals

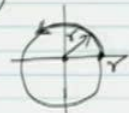

(Refer Slide Time: 10:14)

Ex: (The fundamental integral):

Let $f(z) = z^n$ $n \in \mathbb{Z}$ ($z \neq 0$ if $n < 0$)

Let $\gamma(t) = r e^{it}$ $0 \leq t \leq 2\pi$ ($r > 0$)

Compute $\int_{\gamma} f(z) dz$

$$\begin{aligned}\int_{\gamma} f(z) dz &= \int_0^{2\pi} (r e^{it})^n \cdot r i e^{it} dt \\ &= \int_0^{2\pi} r^{n+1} i \cdot e^{i(n+1)t} dt\end{aligned}$$

And there are, let us actually see one more example. So this is in some sense fundamental integral. This example is very important it keeps coming back to us again and again. We will use this very much, so it is an important example. Let f of z equal z power n . So essentially it is the previous example with z power n instead of Z squared. So, let f of z be z power n , n is any integer z not equal to 0 if n is strictly less than 0 but, that does not matter for us. Let γ of t being your unit circle parameterised as before or we can actually take circle of radius r , where r is positive, 0 less than or equal to. Let me write this γ of t is $r e^{it}$ 0 less than or equal to t less than or equal to 2π .

So this is the circle of radius r ; r is a positive real number. So compute. Well, since r is positive real number, f is definitely defined there on the range of γ and also its continues there, it is actually analytic on γ . So compute the contour integral of f over the contour γ . So this is the integration of r raised to e power $i t$ raise to n ; z raise to n , z comes from the contour. So γ of t raise to n and then times γ prime of t , γ prime is $r i e^{it} dt$ and the parameter interval is 0 to 2π . I apologise, this should be the circle 2π , 2π . So the contour visually is a circle of radius r centred at the origin it starts at r and ends at the same real number, it goes in the contour clockwise direction and ends with the same real number. The calculation is a similar. So you get r power $n+1$, r power $n+1$ integration from 0 to 2π and then you have a i and then you have $e^{i(n+1)t}$ from in here and then $1 e^{it}$ from here.

(Refer Slide Time: 14:01)

The image shows a handwritten derivation of the contour integral of $f(z) = z^n$ over a circle γ of radius r . The derivation is as follows:

$$\int_{\gamma} f(z) dz = \int_0^{2\pi} (r e^{it})^n \cdot r i e^{it} dt$$

$$= \int_0^{2\pi} r^{n+1} i e^{i(n+1)t} dt = \int_0^{2\pi} r^{n+1} i (\cos((n+1)t) + i \sin((n+1)t)) dt$$

$$= \int_0^{2\pi} -r^{n+1} \sin((n+1)t) dt + i \int_0^{2\pi} r^{n+1} \cos((n+1)t) dt$$

So you get a, what you get? Let me write $e^{i(n+1)t}$ as $\cos(n+1)t + i \sin(n+1)t$, like before. so I get integration from 0 to 2π of r^{n+1} times $i \cos(n+1)t + \sin(n+1)t dt$. So this gives me integration from 0 to 2π and the real part is minus $r^{n+1} \sin(n+1)t dt$ and then plus i times integration from 0 to 2π of $r^{n+1} \cos(n+1)t dt$.

(Refer Slide Time: 15:02)

The image shows a digital notepad with the following handwritten content:

$$= \int_0^{2\pi} -r^{n+1} \sin(n+1)t dt + i \int_0^{2\pi} r^{n+1} \cos(n+1)t dt$$

Case I
If $n \neq -1$:

$$\int_r f(z) dz = \left. + r^{n+1} \frac{\cos(n+1)t}{n+1} \right|_0^{2\pi} + i \left. r^{n+1} \frac{\sin(n+1)t}{n+1} \right|_0^{2\pi}$$

$$= 0$$

Case II
If $n = -1$

So, this is minus r^{n+1} . So I will split into the cases, if n is not equal to minus 1. So case 1: if n is not equal to minus 1, in this case you can integrate, you can integrate this piece to get minus r^{n+1} , the integration of \sin is negative \cos , so plus $\cos(n+1)t$ divided by $n+1$ between 0 and 2π . That is clearly 0 plus i times, likewise, $r^{n+1} \sin$ integration of \cos is $\sin(n+1)t$ divided by $n+1$ between 0 to 2π that also 0. So the integration is 0. Case 2: if n is equal to minus 1, then of course, you cannot have $n+1$ in the denominator but, firstly the integrand is just 1 or sorry it is just.

(Refer Slide Time: 16:31)

$$\int_{\gamma} f(z) dz = \int_0^{2\pi} r^{n+1}(\cos t) dt + i \int_0^{2\pi} r^{n+1} \sin t dt$$
$$= 1 \cdot i \cdot 2\pi = 2\pi i$$
$$\int_{\gamma} z^n dz = \begin{cases} 0 & \text{if } n \neq -1 \\ 2\pi i & \text{if } n = -1 \end{cases}$$

So the integrand is 0 to 2 pi minus r power n plus 1 times 0, for the real part because Sin of 0 is 0 and then plus i times integral 0 to 2 pi r power n plus 1 times cosine 0, which is 1 dt. So that you get r power n plus 1, well, n is minus 1. So I can substitute r power 0. So I just get 1 here, 1 times i times 2 pi, so which is 2 pi i. So the contour integral f of z dz where the contour is a circle of radius r centred at 0 and f is z power n is equal to, so let me write z power n instead of f z power n dz, is equal to 0 if n is not equal to minus 1 and its equal to 2 pi i if n equals minus 1. So, this is very important integral this is fundamental integral.

(Refer Slide Time: 18:09)

Exercise: Let $r > 0$ $a \in \mathbb{C}$ & let $\gamma(t) = a + re^{it}$ $0 \leq t \leq 2\pi$

Show that $\int_{\gamma} (z-a)^n dz = \begin{cases} 0 & \text{if } n \neq -1 \\ 2\pi i & \text{if } n = -1 \end{cases}$

Properties: Let γ be a contour with parameter interval $[a, b]$
let f & $g: \mathbb{C} \rightarrow \mathbb{C}$ be continuous. Then

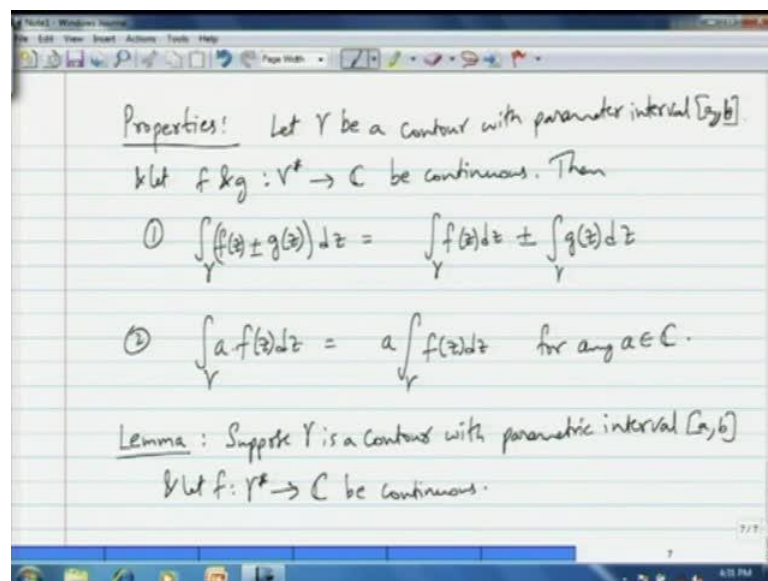

① $\int_{\gamma} (f(z) \pm g(z)) dz = \int_{\gamma} f(z) dz \pm \int_{\gamma} g(z) dz$

We can actually, there is another form of this, we can actually extend this to the following and this is an exercise to the viewer. Let r be greater than 0, like in the previous example, and a be any complex number; a be a given complex number. Let γ of t is $a + re^{it}$ $0 \leq t \leq 2\pi$. Show that the contour integration of the function $z^{-n} dz$ is 0 if n is not equal to minus 1 and $2\pi i$ if n is equal to minus 1.

So this is an extended fundamental integral. So, it is very useful and important for us. γ is a circle of radius r around the point a , r is any positive number. Then, the contour integration of z^{-n} has exactly 2 values 0 or $2\pi i$. So that is an exercise. Now we have some properties of this contour integral, some easy properties, and some properties that we will prove these easy properties quite easy to see, so I would not prove them. The first of them I want to say is that the let I have to state my assumptions, let γ be a contour with parameter interval $[a, b]$.

Let f and g from γ to \mathbb{C} be continuous. Firstly the contour integral over γ of $f(z) + g(z)$ actually plus or minus $g(z) dz$ is the contour integration of f over γ plus or minus the contour integration of g per γ this is something we expect.

(Refer Slide Time: 21:12)

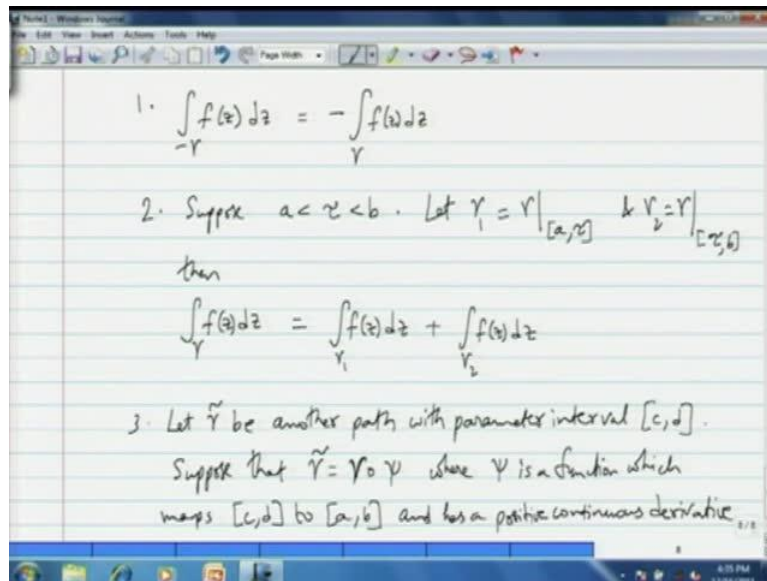

To prove it is very easy, just use the definition of contour integration and likewise if you have a constant times $f(z) dz$ and you want to do contour integration, the constant can

scale out of the contour integration this gamma, for any a belongs to C. So if a is a constant like that its scales out the contour integration.

Next, suppose that, so here I want to state further properties in a Lemma, suppose that gamma is a path or a contour, so I am saying contour, so I will just say contour, with parametric interval a comma b and let f from gamma star to C be continuous, like above, then we have 3 properties.

(Refer Slide Time: 22:49)

The first 1 is that the integration over minus gamma, remember what that is; that is the opposite path to gamma, of f of z dz the contour integral of f over the path minus gamma is the negative of the integral of f over gamma. So that tells us or that is the motivation for why we name that opposite path as minus gamma. So, it is a first property and the second of the properties is that suppose that a is strictly less than Tau strictly less than b, so Tau is some value between a and b. Let gamma 1 be the restriction of gamma to the closed interval a tau and gamma 2 be the restriction of gamma to the interval Tau b. What that means is that you just define gamma 1 of t equals gamma of t, on the interval a comma Tau, you do not care for the definition of gamma 1 outside of this interval a comma Tau.

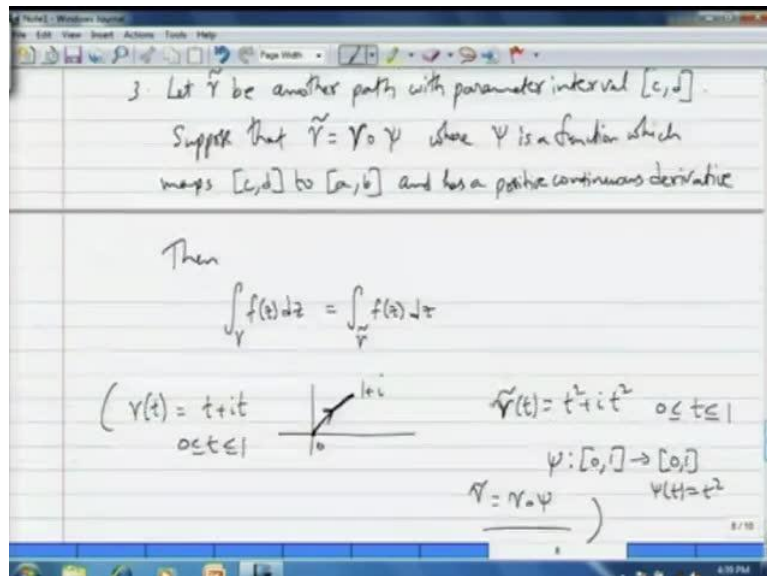

So likewise, gamma 2 is gamma of t on the interval Tau b. Then, the integration, the contour integration of f of z on gamma is actually equal to the contour integration over gamma 1 of f of z dz plus the contour integration of f on the contour gamma 2. So you

can take a parametric interval and split it up into pieces and restrict the original curve to each of these pieces and find the contour integral on each of these pieces and add up to get the original contour integral, mind you can only slice the interval into finite number of pieces.

So in this case we just split it up into 2 pieces and it works. So that is the second part of this lemma. In the third part of this lemma is that if you have what is called as reparameterisation of a contour. So let $\tilde{\gamma}$ be another path with parameter interval c comma d . Suppose that $\tilde{\gamma}$ is γ circle Ψ . So it is the composition of Ψ with γ where Ψ is a function, which maps the interval c d to interval a b and has a positive continuous derivative.

So Ψ is a function from c d to a b . It is a real value, real variable function and Ψ prime is continuous function and also Ψ prime is always positive, that means Ψ is an increasing function and not only that it is also 1 to 1. It is a bisection actually and it is a smooth function. It is a smooth bisection from c d to a b and it is invertible as well, so automatically the inverse function will be smooth as well, smooth according to the definition, restricted definition we give.

(Refer Slide Time: 28:01)

Then the integration of the contour integration of f on γ will be the same as contour integration on $\tilde{\gamma}$ of f . So that is the conclusion. So what this reparameterisation really is that you take a contour and then you look at its range in the

complex plane, so it is a its a curve of certain sort and it has a range, you try to come up with yet another smooth function, smooth curve, such that the range is the same. So you know to quickly exemplify, you look at γ of t equals, let us say, $t + i t$. So this looks like it starts at 0 and ends at $1 + i$; that is the range of this function $0 \leq t \leq 1$. You could also look at $\tilde{\gamma}$ of t equals $t^2 + i t^2$. This is just a motivational example, curves can be much more complicated of course, contours can be much more complicated.

So $0 \leq t \leq 1$ then, $\tilde{\gamma}$ is a re-parameterisation of γ , because you can easily construct a function Ψ from 0 to 1 , such that $\tilde{\gamma}$ is $\gamma \circ \Psi$ and what might that be: Ψ of t is t^2 , Ψ of t is t^2 . So $\tilde{\gamma}$ is $\gamma \circ \Psi$, that is clear, that is easy to verify. So, this $\tilde{\gamma}$ is a re-parameterisation. So you can describe that particular curve you see, the range of γ that you see, you can re-parameterise it in terms of some other function. Then there will, you know you can possibly come up with such a function. When you can, the Lemma says that the contour integral of f tallies with the contour integral of f on $\tilde{\gamma}$.

So this is very need because now it turns out that contour integral really depends only on the range of γ , namely the γ star and not on how you parameterise it, as long as γ satisfies some smoothness conditions etcetera. So under very mild conditions your integration contour integration is really a property of the range γ star.

So having said that we will see the proof of property 3 in this lemma, proof of property 1 and 2 are exercise; they are fairly easy, one has to use the definitions of contour integral. So, 1 and 2 are left as exercises for the viewer. Let us try to see the proof of property 3 here and so it is as follows.

(Refer Slide Time: 31:59)

Proof of 3: $\tilde{\gamma} = \gamma \circ \psi(t) \leftarrow$
 $\tilde{\gamma}'(t) = \gamma'(\psi(t)) \psi'(t) \leftarrow$

$$\int_{\tilde{\gamma}} f(z) dz = \int_c^d f(\tilde{\gamma}(t)) \tilde{\gamma}'(t) dt$$
$$= \int_c^d f(\gamma(\psi(t))) \gamma'(\psi(t)) \psi'(t) dt$$

Proof of 3: So gamma tilde is gamma circle Psi, gamma tilde of t so suppressing the t here. Since psi is differentiable, gamma is differentiable, the composition is differentiable and so gamma tilde prime of t by using the chain rule is gamma prime of Psi of t times Psi prime of t that is the chain rule.

So using the chain rule you get this. We will use this to do the following. So the contour integral over gamma tilde of f of z dz is by the definition c to d, that is parameter interval for gamma tilde, of f of gamma tilde of t times gamma tilde prime of t dt. That is the definition of, that is by the definition of, contour integration and gamma tilde of t and gamma tilde prime of t are here. So I am going to substitute them here. So this is integration from c to d of f of gamma circle Psi of t. So, gamma circle Psi of t is gamma of Psi of t; that is the definition of composition. Then gamma tilde prime is gamma prime of Psi of t times Psi prime of t dt.

At this stage I have eliminated gamma tilde and brought in gamma just using the definition or just using the equality right here.

(Refer Slide Time: 34:20)

The image shows a digital notepad with handwritten mathematical notes. The first part defines a substitution $\tau = \psi(t)$. It states that when $t=c$, $\tau = \psi(c) = a$, and when $t=d$, $\tau = \psi(d) = b$. The differential is given as $d\tau = \psi'(t) dt$. The main equation shows the transformation of an integral: $\int_{\gamma} f(z) dz = \int_a^b f(\psi(t)) \psi'(t) dt = \int_{\tilde{\gamma}} f(z) dz$. Below this, an example is given: "Ex. Compute $\int_{\gamma} z^2 dz$ where γ is a contour formed by".

Then now I will make a substitution, let Tau be equal to Psi of t. So, that d tau is psi prime of t dt. When t equals c, Tau is Psi of c, which will be a and when t equals d for upper limit of integration Tau will be Psi of d or rather psi of d, which will be equal to b. Recall Psi is a monotone function, monotonously increasing function and it maps a to c to a and d to b ok.

So then the contour integration over gamma tilde of f of z dz will equal, with the substitution, it will equal the integration from a to b. Now, we will write everything in terms of Tau. So you get f of gamma of Tau because Psi of t is Tau, now and then gamma prime of Psi of t is Tau and Psi prime of t d t is your d Tau. This now exactly looks like well, it is the contour integration over gamma of f of z dz. That proves that these two integrals are one and the same. With that we can really talk about computing contour integrations on certain contour spoken off as curves in the complex plane or as ranges in the complex plane.

(Refer Slide Time: 36:47)

Ex: Compute $\int_{\gamma} z^2 dz$ where γ is a contour formed by joining $\gamma_1: [-R, R]$ & $\gamma_2: Re^{it} \ 0 \leq t \leq \pi$

$\gamma_1(t) = -R(1-t) + Rt$

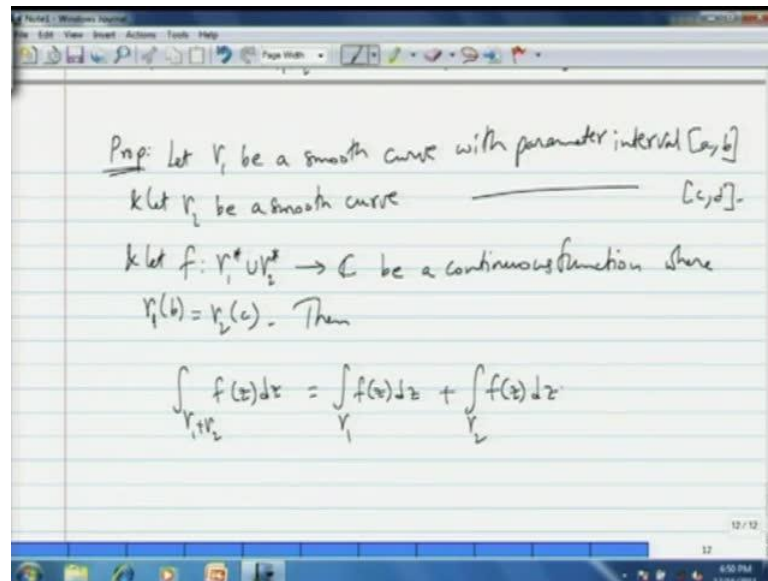

$\int_{\gamma} z^2 dz = \int_{\gamma_1 + \gamma_2} z^2 dz = \int_{\gamma_1} z^2 dz + \int_{\gamma_2} z^2 dz$

So here is an example. So compute the contour integral $z^2 dz$, where γ is a contour formed by joining γ_1 the interval $[-R, R]$ and γ_2 which is Re^{it} $0 \leq t \leq \pi$. So, compute the contour integration where only the range of γ_1 is given, here is your $-R$, here is your R and Re^{it} is semicircle in the counter clockwise direction and this is your γ_1 and this is your γ_2 and this is the join.

So if you observe the parameterisation of γ_1 has not been given to us, it is just, you know, it can be parameterised in any way you please owing to the lemma property 3 of this lemma above because, any way you parameterise or any smooth way you parameterise, γ_1 is going to give you the same result. So, the contour integration over γ of $z^2 dz$; let us first write a parameterisation for γ_1 . γ_1 can be described as $-R(1-t) + Rt$.

So then we are almost all set, I am saying almost for a reason, the integration to compute the contour integration of $z^2 dz$ over the contour γ . Now if I can split this into, well γ is the join of γ_1 and γ_2 . So, it would be nice if I can split this into the contour integration over γ_1 plus contour integration over γ_2 of $z^2 dz$. So, let us see that I can indeed do this when γ_1 and γ_2 are smooth at least.

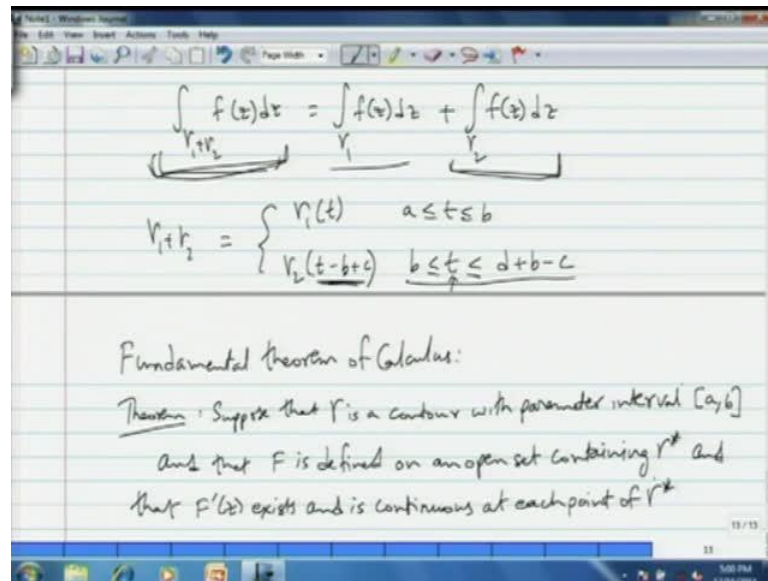

(Refer Slide Time: 39:28)

So here is the proposition, like in the above lemma let γ_1 and γ_2 also let γ_1 be a smooth curve with parameter interval a, b and let γ_2 be a smooth curve with the parameter interval c, d . Let f from $\gamma_1 \cup \gamma_2$ to \mathbb{C} be a continuous function where $\gamma_1(b) = \gamma_2(c)$.

So what that means is that the end point of γ_1 is equal to the initial point, the final point of γ_1 is equal to the initial point of γ_2 , so that I can form the join of γ_1 and γ_2 . Then the conclusion is that the contour integral of f on the join of γ_1 and γ_2 is indeed equal to the contour integral of f on γ_1 plus the contour integral of f on γ_2 . The proof involves the fact that you can shift the parameter interval and yet get the same value of the contour integration.

(Refer Slide Time: 41:46)

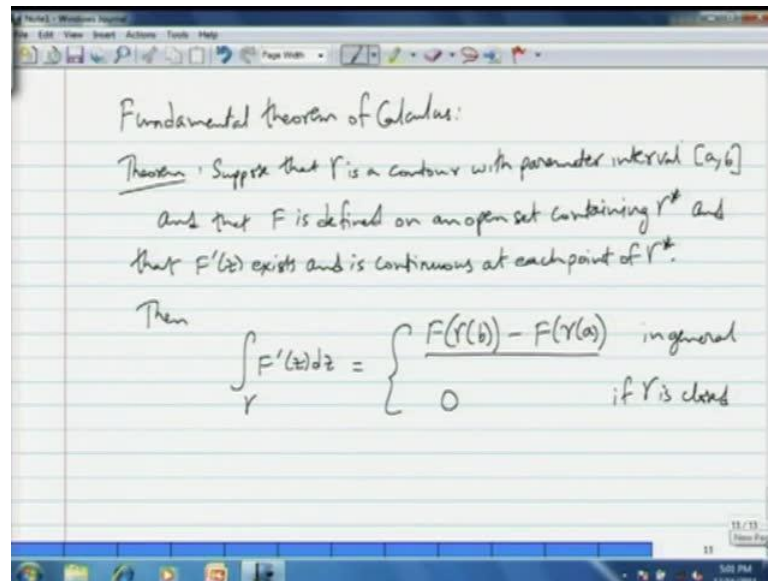

So recall gamma 1 plus gamma 2 is defined in certain way you go from a to b for gamma 1 and you go from b to not exactly d but, you go until d plus b minus c, for tracing gamma 2; where gamma 2 is t minus b plus c. Gamma 2 the parameter for gamma 2 will be t minus b plus c. So there is a shift here we shifted the interval c d to b comma d plus b minus c, so we have made a shift, but we have anyway balanced for that using this parameter t minus b plus c .

So that will take care of that and you can show that, using the definition of contour integral you can show that, this turns out, the first piece is not a problem but, the second piece turns out due to this balancing act. So that is easy to prove that is left to the viewer as an exercise. Next I want to talk about a fundamental theorem of calculus for complex integrals for contour integrals of this sort.

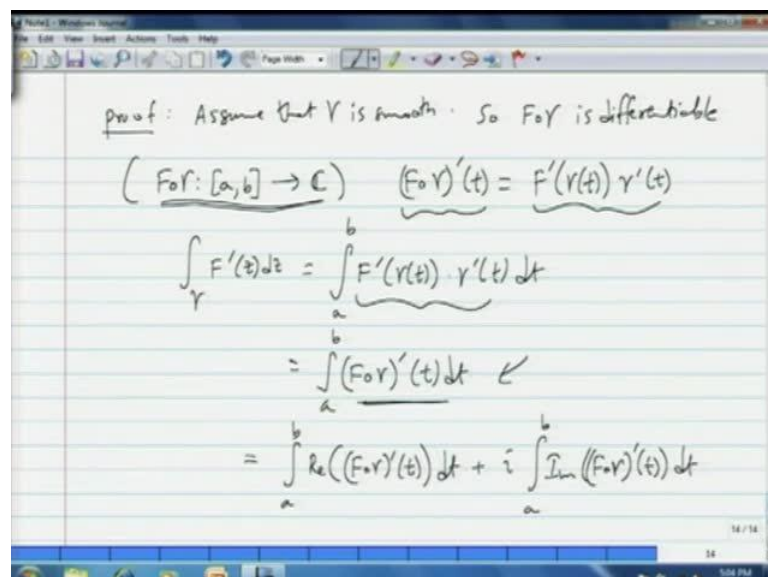

So the fundamental theorem of calculus, so here is the theorems, statement of the theorem. So suppose that gamma is a path, a contour with parameter interval a comma b and that capital f is defined on an open set containing gamma star and that F prime of z exists and is continuous at each point of gamma star.

(Refer Slide Time: 44:48)

So then the contour integral over gamma of F prime of z dz is equal to F of gamma of b minus capital f of gamma of a in general and 0 in particular when if gamma is closed. So there is no real need of bifurcation. If gamma is closed, gamma of p is equal to gamma of a. So the subtraction is automatically 0. So, this is the fundamental theorem of calculus in this context and we will see the proof of this.

(Refer Slide Time: 45:47)

It is really easy. So assume that gamma is smooth to begin with. So we will relax this for the time being let us assume that it is smooth. Now the hypothesis on f that it is

differentiable on an open set containing γ^* allows us to say that $F \circ \gamma$ is differentiable. Notice $F \circ \gamma$ is a function from the parameter interval $[a, b]$ to the complex plane.

So $F \circ \gamma$; note, $F \circ \gamma$ is a function from the parameter interval $[a, b]$ to the complex plane. It is a composition of a smooth function and a differentiable function so it is differentiable, of course. So let us compute the derivative using the chain rule $(F \circ \gamma)'(t) = F'(\gamma(t)) \cdot \gamma'(t)$. So F' exists at every point $\gamma(t)$. So it is $F'(\gamma(t))$ and then times $\gamma'(t)$ smooth by assumption. So γ' exists as well. So that is the derivative.

So in order to compute the contour integral $\int_{\gamma} F'(z) dz$ on the contour γ , we need to use the definition. This is integration from a to b of $F'(\gamma(t)) \gamma'(t) dt$. But, the integrand is nothing but, the derivative of $F \circ \gamma$. So this is the integration from a to b of $(F \circ \gamma)'(t) dt$.

So $F \circ \gamma$ is a function from the interval $[a, b]$ to \mathbb{C} and it's differentiable. So the derivative, and the derivative is continuous as well, so the derivative function here is being integrated and we define this kind of integral to be the integration of the real part of this function $(F \circ \gamma)'(t)$, which is a continuous function, dt plus i times the integration from a to b of the imaginary part of $(F \circ \gamma)'(t) dt$, that is the definition of an integral of this kind.

(Refer Slide Time: 48:53)

$$= \operatorname{Re}(F \circ \gamma(t)) \Big|_a^b + i \operatorname{Im}(F \circ \gamma(t)) \Big|_a^b$$

$$= F \circ \gamma(t) \Big|_a^b = F(\gamma(b)) - F(\gamma(a))$$

If γ is piecewise smooth

$$\int_{\gamma} F(z) dz = \sum_{k=0}^{n-1} \int_{t_k}^{t_{k+1}} F'(\gamma(t)) \gamma'(t) dt$$

where $\gamma|_{[t_k, t_{k+1}]}$ is smooth

So that is by the real fundamental theorem of calculus, the fundamental theorem of calculus for a real functions, this is nothing but the real part of $f \circ \gamma$ of t between the limits a and b plus i times the imaginary part of $F \circ \gamma$ of t between the limits a and b . When we add, of course, we get $F \circ \gamma$ of t between a and b . So that is F of γ of b minus F of γ of a and that proves the theorem. Of course, when γ is a closed curve, well let me add something but, when γ is a closed curve of course, this difference is 0 because γ of b is equal to γ of a . If γ is piecewise smooth, all you have to do is split this contour integration like one of the properties in Lemma, we have seen earlier. We have to split this into pieces k equals 0 to n minus 1 the integration from t_k to t_{k+1} of F prime of γ of t γ prime of t dt where γ restricted to any of these intervals t_k comma t_{k+1} .

So its piecewise smooth, so you can separate the interval, parameter interval, a b into pieces such that it is smooth on each of these piece. These are finitely many pieces. So what I am doing is adding up the integrals on those pieces. Now you can apply what we have done before.

(Refer Slide Time: 51:15)

The image shows a digital notepad with a menu bar (File, Edit, View, Insert, Actions, Tools, Help) and a toolbar. The main content is handwritten in black ink on a white background with horizontal lines. The first part shows the equation $\int_{\gamma} F(z) dz = \sum_{k=0}^n \int_{t_k}^{t_{k+1}} F'(v(t)) \gamma'(t) dt$. Below this, it says "where $v|_{[t_k, t_{k+1}]}$ is smooth". A horizontal line separates this from the second part, which says "Apply previous to $\int_{t_k}^{t_{k+1}} F'(v(t)) \gamma'(t) dt$ ".

So apply previous to what we have done before to each of these t_k to t_{k+1} F' prime of γ of t γ' prime of t dt. Then what you get is the telescoping kind of sum and you end up with F of γ of b minus F of γ of a . So that piece I will leave to you, it is easy. So that is the end of this proof.
