**Open mapping theorem – Part two**

Hello viewers, in the previous session, we have proved the following theorem. This theorem states that, if  $f$  of  $z$  is analytic at  $z_0$  and  $f$  of  $z_0$  equals  $w_0$  and that  $f$  of  $z$  minus  $w_0$  has order  $n$  at  $z_0$ .

(Refer Slide Time: 00:24)

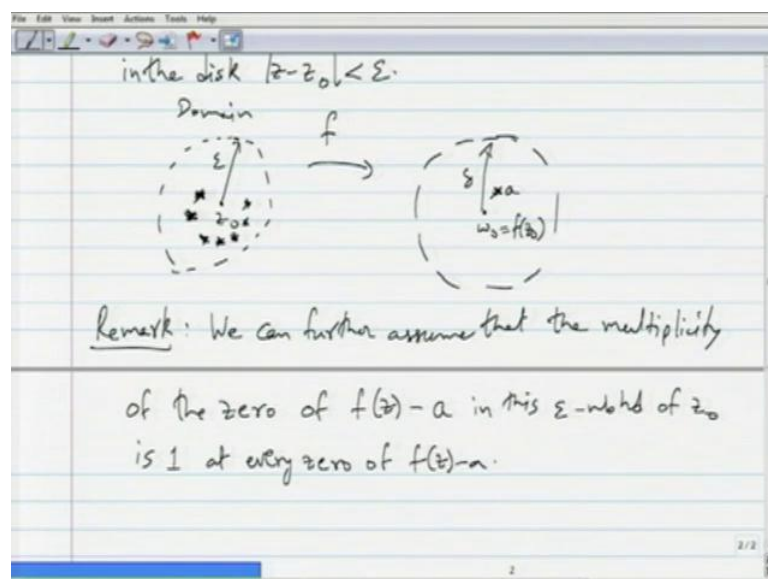

Under these circumstances, if  $\epsilon$  is positive then there is a corresponding  $\delta$  positive, such that all the values in the  $\delta$  neighbourhood of  $w_0$  are taken exactly  $n$  times by  $f$ , in the  $\epsilon$  neighbourhood of  $z_0$ .

(Refer Slide Time: 01:00)

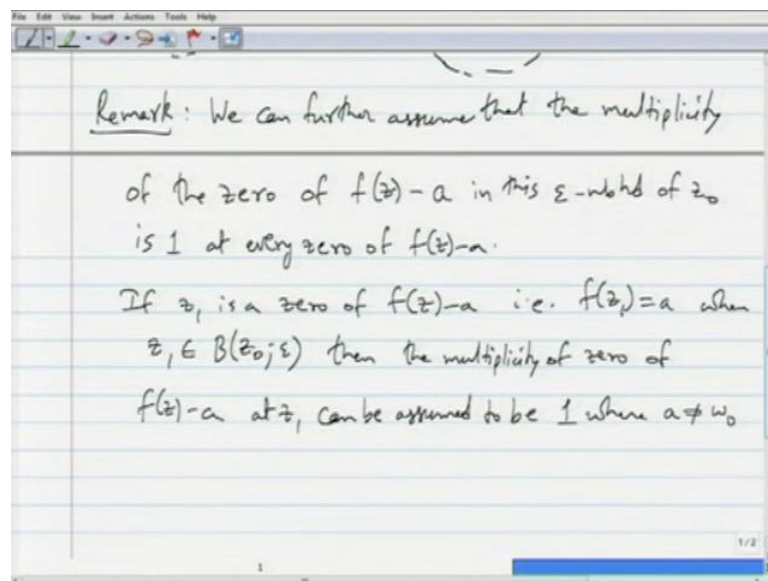

So, a picture for this is definitely in order. So, here is an epsilon neighbourhood of  $z_0$ , so this is the domain and this is the range. So, here is  $w_0$  equals  $f$  of  $z_0$  and  $f$  takes  $z_0$  to  $w_0$ , okay? So, now if this epsilon is sufficiently small though, then also the  $\delta$  of  $f$  of  $z$  minus  $w_0$  is of order  $n$ , then each point in this neighbourhood. So, let us call  $a$ , let us pick an  $a$ , in this  $\delta$  neighbourhood, this is a  $\delta$  neighbourhood of  $w_0$ . So, each point  $a$  is assumed  $n$  times here there are  $n$  points here counting multiplicity such that  $f$  of  $z$  is equal to  $a$  for these points in the, for these points in the epsilon neighbourhood. That is what this theorem asserts.

(Refer Slide Time: 02:26)

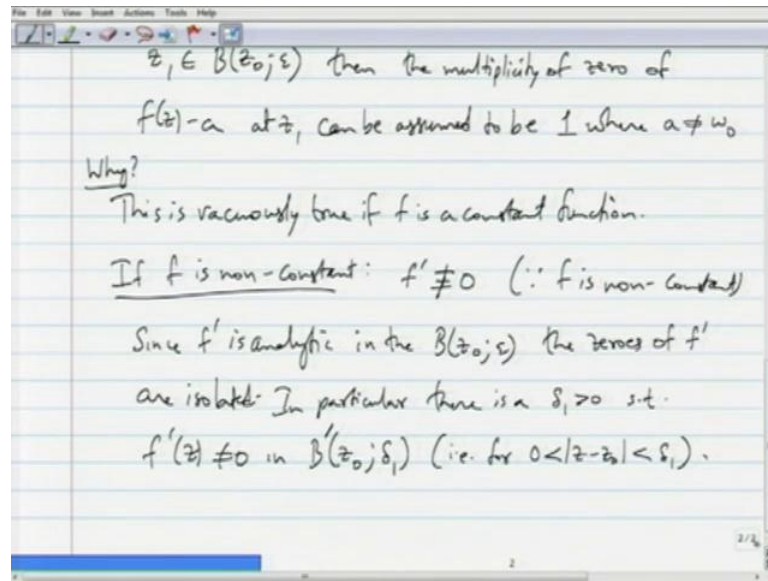

So, a remark is in order here, we can further assume that the multiplicity of  $f(z) - a$  at each of these points is actually 1. What I mean by that is remark, so I will remark that we can further assume that the multiplicity, or I will say the multiplicity of the 0 of  $f(z) - a$  in this epsilon neighbourhood. So, I am referring to the theorem under the conditions of the theorem in this epsilon neighbourhood of  $z_0$  is 1 at every 0 of  $f(z) - a$ .

(Refer Slide Time: 03:52)

What I mean by that is if  $z_1$  is a 0 of  $f(z) - a$  i.e.  $f(z_1) = a$ , where  $z_1$  belongs to  $B(z_0, \epsilon)$ . So,  $z_1$  is a solution to  $f(z) = a$  and  $z_1$  belongs to epsilon neighbourhood around  $z_0$ . Then the multiplicity of 0 of  $f(z) - a$  at  $z_1$  can be assumed to be 1 or it can be said to be a simple 0, where there is an assumption where  $a$  is not equal to  $w_0$ , okay? So, for anything other than  $w_0$ , so if I pick any  $a$  here, I am referring to this picture here now, if I pick any  $a$  here which is not  $w_0$  itself, then each of these points which hits  $a$  it is 0 of  $f(z) - a$ . Then the multiplicity of 0 at that point  $z_1$  of  $f(z) - a$  can be assumed to be 1.

(Refer Slide Time: 0:43)

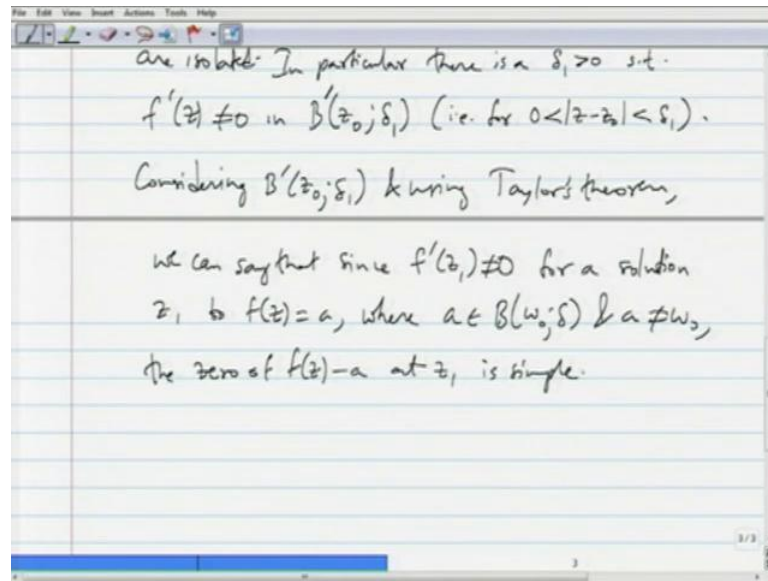

Why is it so? Well firstly this why? The answer is as follows, this is vacuously true, if  $f$  is a constant function, right? If  $f$  is a constant function, there is no other  $a$  that we can pick other than  $w_0$  because all the points are mapped to this  $w_0$  itself. It is a constant function. So, we can assume that  $f$  is a non-constant function, if  $f$  is non-constant, we can do the following. Notice that  $f'$  is not identically the 0 function. Why? Well because if  $f$  is analytic,  $f'$  is analytic and  $f'$  is identically 0 on an open set gives you that  $f$  is constant on the components on which  $f$  is analytic.

So,  $f'$  is not identically 0, if  $f'$  is identically 0  $f$  is constant on the ball at least. So since  $f$  is non-constant and since  $f'$  is an analytic function, the zeros of  $f'$  are isolated, by the identity theorem if you wish. So, since  $f'$  is analytic as well, in the  $\epsilon$  ball if you wish  $f'$  is not 0 in  $B(z_0; \delta_1)$  the zeros of  $f'$  are isolated. In particular there is a  $\delta_1 > 0$  such that  $f'(z) \neq 0$  in  $B(z_0; \delta_1)$ , okay?

So, even if  $f'$  is 0 at  $z_0$ , there is a small neighbourhood around  $z_0$  such that  $f'$  is not 0 in  $B(z_0; \delta_1)$  so i.e., this is i.e. for  $0 < |z - z_0| < \delta_1$ . That is a deleted neighbourhood of  $z_0$ .

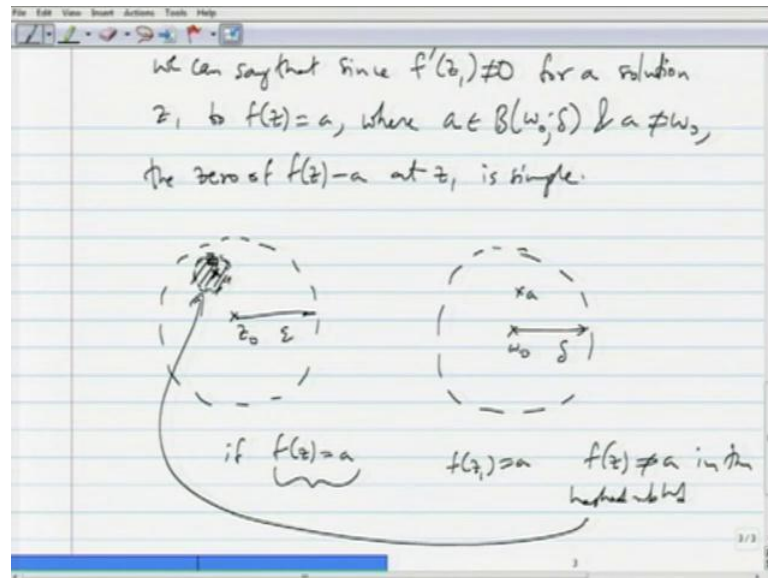

(Refer Slide Time: 09:01)

So, what this gives us is that then considering  $B'$  or  $B$  prime  $z$  naught  $\delta_1$  which is an open set and using Taylor's theorem if you wish, we can say that since  $f'$  prime of  $z_1$  is not equal to 0, well here  $z_1$  is the 0 of  $f$  of  $z$  minus  $a$ , okay? So we can say that since,  $f'$  prime of  $z_1$  is not equal to 0 for a solution  $z_1$  to  $f$  of  $z$  is equal to  $a$ , where  $a$  belong to the  $\delta$  neighbourhood of  $w$  naught and  $a$  not equal to  $w$  naught. The 0 of  $f$  of  $z$  minus  $a$  at  $z_1$  is simple you expand  $f$  of  $z$  minus  $a$   $f$  of  $z$  minus  $a$  is also an analytic function. So, you expand  $f$  of  $z$  minus  $a$  around  $z_1$ .

So, since  $f'$  prime of  $z_1$  is non-zero, you have that the the 0 at  $z_1$  of  $f$  of  $z$  minus  $a$  has to be simple. That is by the Taylor's expansion for  $f$  of  $z$  minus  $a$  around  $z_1$ , so that says that you are, so these zeros can be assumed to be simple the zeros of  $f$  of  $z$  minus  $a$  can be assumed to be simple, okay?

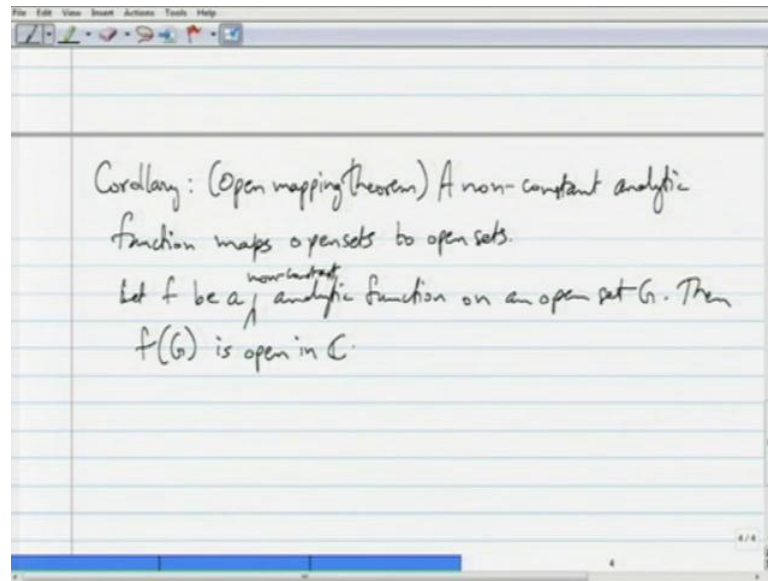

(Refer Slide Time: 10:56)

So what that is telling us is that here once again the picture here is, here is  $w$  naught here is  $z$  naught. If I pick any  $z$  which gets mapped on to some  $a$  in the delta neighbourhood of  $w$  naught, this is the delta neighbourhood of  $w$  naught, this is the epsilon neighbourhood of  $z$  naught as in the theorem. And if  $f$  of  $z$  is equal to  $a$  then there is a small neighbourhood of this  $z$ , such that  $z$  is the only well I do not need a neighbourhood here, this is  $a$ .

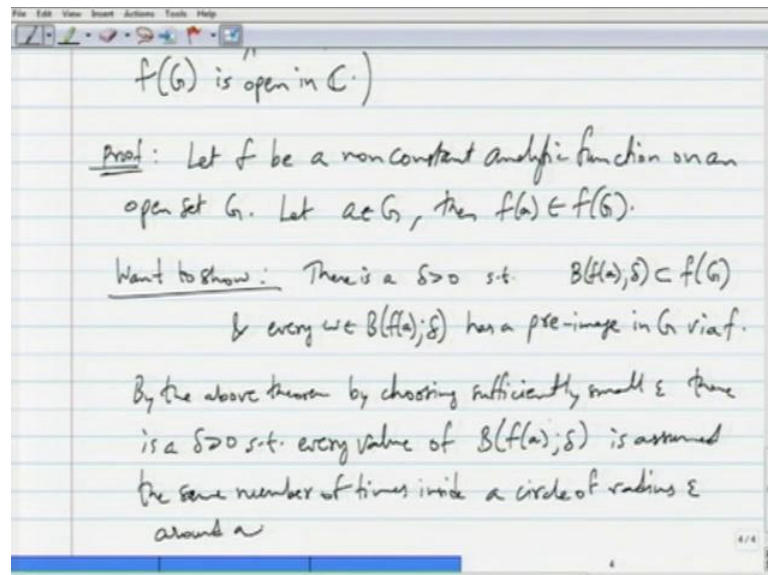

So, in this small neighbourhood here this small neighbourhood here of  $z$   $z$  is the only solution to  $f$  of  $z$  is equal to  $a$ . So, this is  $z_1$ , so then  $f$  of  $z_1$  is equal to  $a$  and  $f$  of  $z$  is not equal to  $a$  in the hashed neighbourhood hashed as in this this picture, this this pictured neighbourhood, okay? Now, we are a ready to prove the open mapping theorem as a corollary to the we had last time.

(Refer Slide Time: 12:24)

So, a non constant analytic function maps open sets to open sets i.e., so stated in another way let  $f$  be an analytic function, non constant. Let  $f$  be a non constant analytic function on an open set  $G$ , then  $f(G)$  is open in  $\mathbb{C}$ .  $G$  is open open set in  $\mathbb{C}$  then  $f(G)$  is open set in  $\mathbb{C}$  as well. So, this is another way of stating the same all right?

(Refer Slide Time: 13:46)

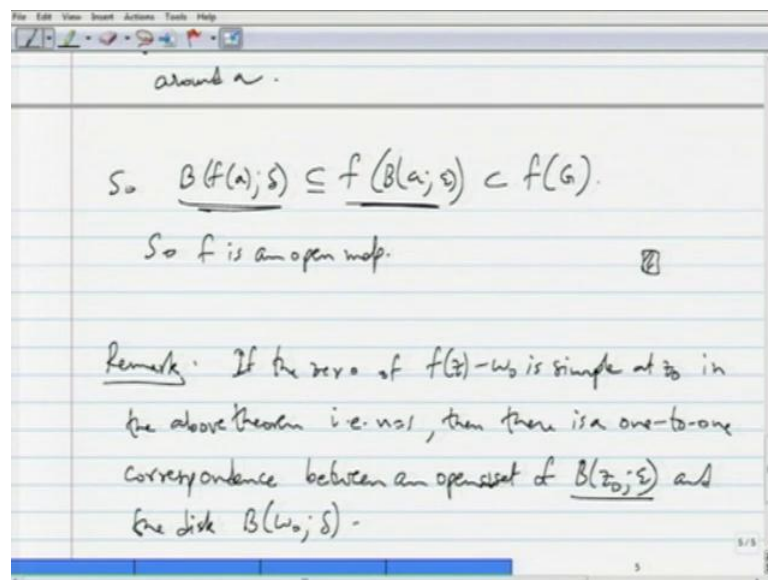

So, what is the proof? Well the proof follows from the theorem above. So, what do we need to show, let  $f$  be a non constant analytic function on an open set  $G$ . We have to show that  $f(G)$  is open. So, let  $a$  belong to  $G$ , and then  $f(a)$  is in  $f(G)$ .

belongs to  $f$  of  $G$ . So, we want to show that there is a  $\delta$  positive such that  $B$  of  $f$  of  $a$   $\delta$  is contained in  $f$  of  $G$  and every  $w$  belongs to  $B$  of  $f$  of  $a$   $\delta$ , has a pre image in  $G$  via  $f$ . This is what we want to show.

So, this comes directly from the previous theorem. So, by the above theorem by choosing sufficiently small  $\epsilon$  there is a  $\delta$  positive, such that every value of  $B$  of  $f$  of  $a$ . Well  $f$  of  $a$  itself is assumed by  $a$  by  $f$  at the point  $a$ . So,  $B$  of  $f$  of  $a$   $\delta$  is assumed the same number of times inside a circle of radius  $\epsilon$  around  $a$ . So,  $f$  of  $a$  itself like a remarked is assumed by  $f$  at  $a$ . So, all the values in this ball are assumed by  $f$  at least once.

(Refer Slide Time: 16:32)

So, that is the point. So  $B$  of  $f$  of  $a$   $\delta$  is contained in the image of the ball of  $\epsilon$  radius around  $a$  via  $f$ . So, this is the point and then this is contained in  $f$  of  $G$ . So,  $f$  is an open map. So, that completes the proof of this theorem. And that is a very important result. We will see that the maximum modulus principle follows as a consequence, there is a remark following this corollary if the 0 of  $f$  of  $z$  minus  $w$  naught is simple at  $z$  naught in the above theorem i.e.  $n$  is equal to 1.

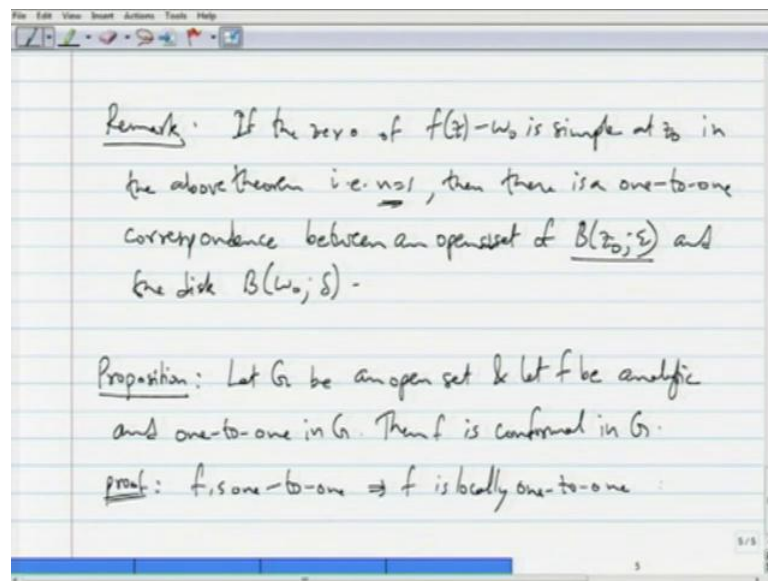

So, in this theorem here, in the first theorem that I quoted; so if  $n$  is equal to 1 the 0 of  $f$  of  $z$  minus  $w$  naught is simple. Then there is a one to one correspondence between an open set, open set of  $f$  of  $z$  minus sorry, between open set of  $B$   $z$  naught  $\epsilon$ ; so between open subset rather, subset of this ball and the disk  $B$   $f$  of  $z$  naught namely  $w$  naught  $\delta$ ,

right? Because each each value in  $B(w, \delta)$  is assumed exactly one time by by some point in a  $B(z, \epsilon)$ .

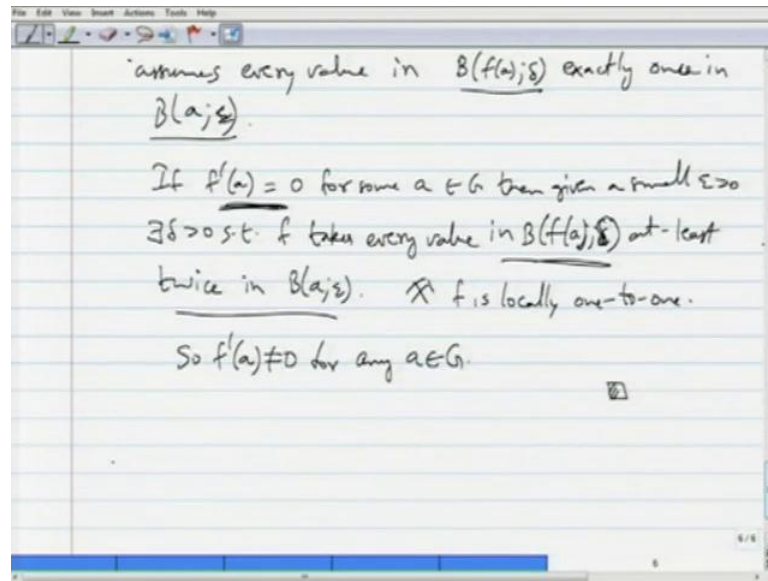

So, there is some open subset here by the open mapping theorem. We can say that an open set is carried to this here and then so an open set open subset of  $B(z, \epsilon)$  is is is mapped in one to one fashion to  $B(w, \delta)$ .

(Refer Slide Time: 19:35)

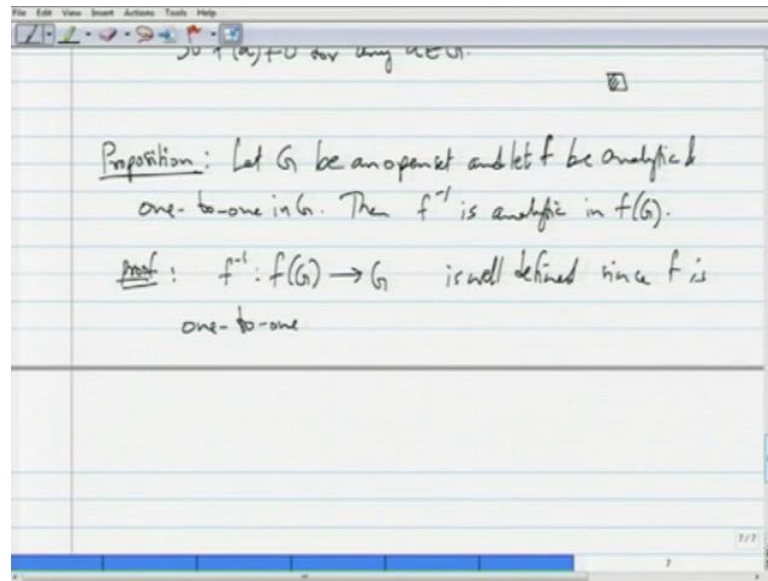

That is a remark and then we will see some some more results following from this important theorem we we saw in the last session. So, here is a case where we are assuming  $n$  is equal to 1. So, here is a proposition let  $G$  be an open set. And let  $f$  be a analytic and one to one in  $G$  then  $f$  is conformal in  $G$ . Here is the proof in detail, so  $f$  is one to one implies  $f$  is locally one to one. What I mean by locally is that, there is a neighbourhood around every point, where it is one to one.

(Refer Slide Time: 20:41)

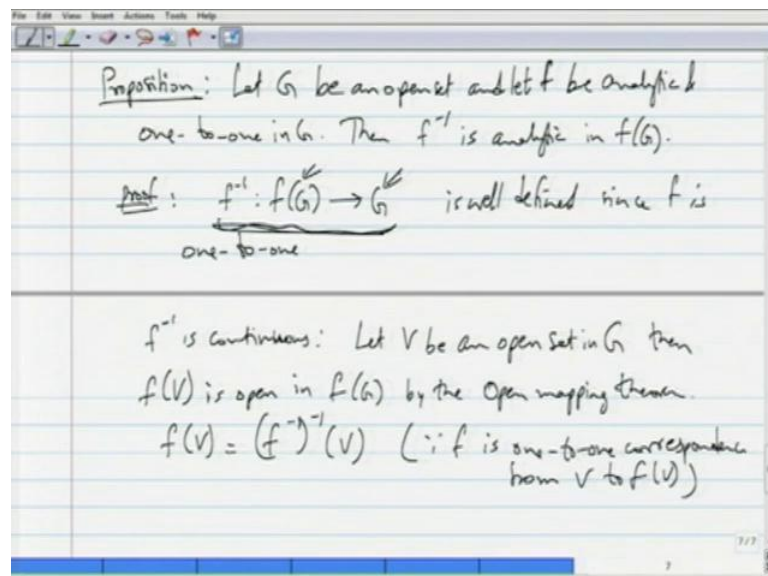

If  $f'(a) = 0$  for some arbitrary point  $a$  in  $G$ , then given a small  $\epsilon > 0$ , there exists a  $\delta > 0$  such that  $f$  takes every value in  $B(f(a), \delta)$  at least twice in  $B(a, \epsilon)$ . This is because if  $f'(a) = 0$ , then the order of the zero of  $f(z) - f(a)$  at  $a$  is at least 2. So, by the remark earlier, we can assume that in a small neighborhood of  $a$ , the number of zeros of  $f(z) - w$  is simple or equal to 1, okay? Or the multiplicity of such zeros is equal to 1, so what that means is, that every value in  $B(f(a), \delta)$  has to be taken at least twice in  $B(a, \epsilon)$ . So, that is the contradiction since  $f$  is locally one-to-one. So, that says  $f'(a) \neq 0$  for any  $a \in G$ .

(Refer Slide Time: 22:46)

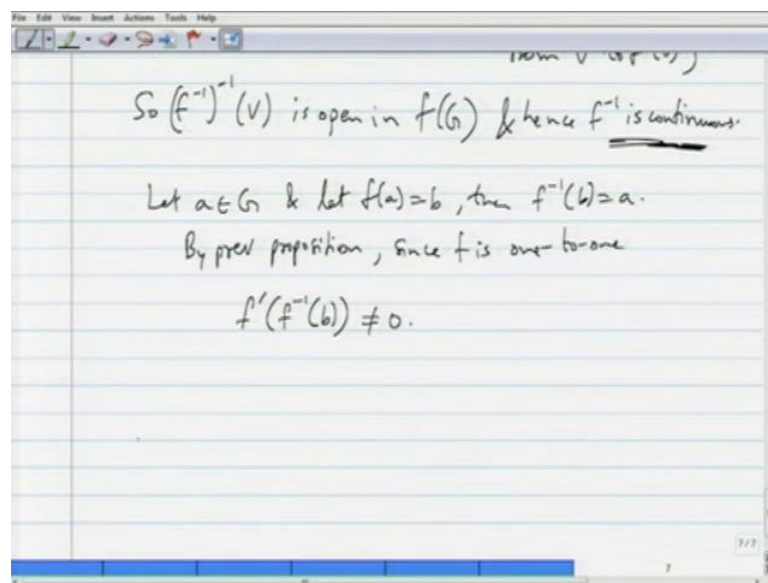

Another consequence that we can speak here is another proposition. So, let once again here we are dealing with one to one analytic functions, let  $G$  be an open set and let  $f$  be a analytic and one to one in  $G$ . Then  $f$  inverse is analytic in  $f$  of  $G$ , so firstly note that since  $f$  is one to one on  $G$   $f$  inverse from  $f$  of  $G$  to  $G$  is well defined. Since,  $f$  is one to one further as a consequence of open mapping theorem; we can note that  $f$  inverse is firstly continuous, okay?

(Refer Slide Time: 24:17)

So,  $f^{-1}$  is continuous here is the argument. So, let so what I will show is the inverse image of an open set in  $G$ . So, here is  $f^{-1}$  from  $f(G)$  to  $G$ . If I pick an open set here I will show that the inverse image of that is open in  $f(G)$ . So, let  $V$  be an open set in  $G$  then  $f(V)$  is open in  $f(G)$ , because of the open mapping theorem, by the open mapping theorem. So, also notice that  $f(V)$  is  $f^{-1}$  inverse of its  $f^{-1}$  inverse of  $V$ . What I mean by that is, it is the inverse image under  $f^{-1}$  of the set  $V$ . Since, this is because  $f$  is one to one, is one to one correspondence more. So, it is a bijection one to one correspondence from  $V$  to  $f(V)$ .

(Refer Slide Time: 26:07)

So, the inverse image of  $f^{-1}$  of  $V$  is nothing but  $f(V)$ ; so so  $f^{-1}$  inverse inverse so  $f^{-1}$  inverse inverse of  $V$  is open in  $f(G)$  and hence that that tells that  $f^{-1}$  is continuous. We have shown that the inverse image of an arbitrary open set in  $G$  is open in  $f^{-1}$  in  $f(G)$  under  $f^{-1}$ . So,  $f^{-1}$  is continuous. Let  $a$  belong to  $G$  and  $f$  of  $a$ , and let  $f$  of  $a$  is equal to  $B$ . Then  $f^{-1}$  of  $B$  is equal to  $a$ . So, I want to show that  $f^{-1}$  is analytic at  $f$  of  $a$  and every point in  $f(G)$  looks like  $f$  of  $a$ .

So, I will be done if I show that  $f^{-1}$  is analytic at the point  $f$  of  $a$  by previous proposition. We have shown that since  $f$  is one to one, we have shown that once we have a one to one function on open set  $f'$  is non zero or  $f$  is conformal. So,  $f'$  of  $f^{-1}$  of  $B$  namely  $f'$  at  $a$  is non-zero. Now, here is where I will actually use a continuity which I showed separately here of  $f^{-1}$ , okay?

(Refer Slide Time: 27:55)

$$f'(f(b)) \neq 0.$$

Now  $\lim_{z \rightarrow b} f^{-1}(z) = f^{-1}(b)$  by continuity of  $f^{-1}$

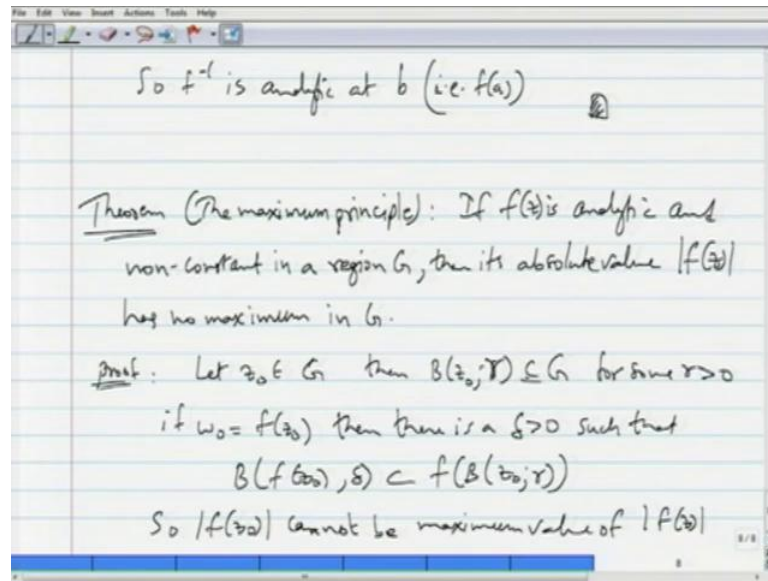

$$\text{So } \lim_{z \rightarrow b} \frac{f^{-1}(z) - f^{-1}(b)}{z - b} = \lim_{z \rightarrow b} \frac{f^{-1}(z) - f^{-1}(b)}{f(f^{-1}(z)) - f(f^{-1}(b))}$$

$$= \lim_{f^{-1}(z) \rightarrow f^{-1}(b)} \frac{1}{\left[ \frac{f(f^{-1}(z)) - f(f^{-1}(b))}{f^{-1}(z) - f^{-1}(b)} \right]} = \frac{1}{f'(f^{-1}(b))}$$

So, now since the limit as  $z$  goes to  $B$  of  $f$  inverse of  $z$  is equal to  $f$  inverse of  $B$ . So, this is why I need continuity in the first place and then I can show differentiability in the standard order, by a continuity of  $f$  inverse. So, the limit as  $z$  goes to  $B$  of  $f$  inverse of  $z$  minus  $f$  inverse of  $B$  by  $z$  minus  $B$ . This is the difference quotient and the limit of the difference quotient. So, I want to show that this limit exists and then I will be able to conclude that  $f$  inverse is differentiable.

So, this is equal to the limit as  $z$  goes to  $B$  of  $f$  inverse of  $z$  minus  $f$  inverse of  $b$ . I am preserving the numerator and I am writing the denominator as  $f$  inverse  $f$  of  $f$  inverse of  $z$  minus  $f$  of  $f$  inverse of  $B$ , okay? So, this is equal to, so what I will do is, I will say this is limit as  $f$  inverse of  $z$  goes to  $f$  inverse of  $B$  limit as  $z$  goes to  $B$  is the same as limit as  $f$  inverse of  $z$  goes to  $f$  inverse of  $B$  because  $f$  is one to one and  $f$  inverse is continuous. So, this is  $1$  divided by  $f$  of  $f$  inverse of  $z$  minus  $f$  of  $f$  inverse of  $B$  divided by  $f$  inverse of  $z$  minus  $f$  inverse of  $B$ . So, notice that the denominator is nothing but the differentiation of  $f$  at  $f$  inverse of  $p$  and we know that is non zero. So, this is equal to one by  $f$  prime of  $f$  inverse of  $B$ . So, this makes sense this thing makes sense because you know  $f$   $f$  is conformal at  $f$  inverse of  $p$ , okay?

(Refer Slide Time: 30:16)

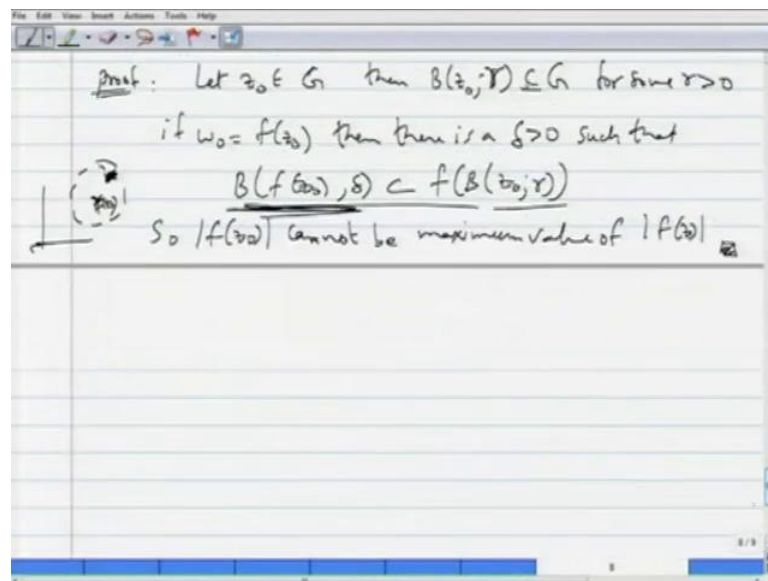

So,  $f$  inverse is as a conclusion we can say that  $f$  inverse is analytic at  $B$  i e  $f$  of  $a$  and since  $f$  is on to  $f$  of  $G$   $f$  of capital  $G$  every point in  $f$  of capital  $G$  looks like  $f$  of  $a$  for some  $a$  in  $G$ . So,  $f$  inverse is essentially analytic on all of  $f$  of  $G$ . So, that completes the proof of this proposition. So, in the case that  $f$  is one to one, we can say more we can on an open set  $G$  we can say more we can say that  $f$  is conformal on that open set. We can also say that the inverse function is analytic.

So, these are two conclusions we can make from the theorem that I wrote at the beginning of the session. In the case where  $n$  is equal to 1 all right? So, next we will see that we can deduce the maximum principle as a consequence of the open mapping theorem. So, theorem the maximum principle, so if  $f$  of  $z$  is analytic and non constant in a region  $G$ , then its absolute value modulus of  $f$  of  $z$  had no maximum in  $G$ . So, we want  $G$  to be a region when modulus of  $f$  of  $z$  has no maximum in  $G$ , okay?

So, we stated the maximum principle before in a slightly different version and there I remarked that it can be directly proved using the local version of the maximum modulus principle that we have already seen. So, but we wanted to take a different root we wanted to prove the open mapping theorem first and deduce this theorem as a corollary to that. So, there is a there is a merit to it this shows that I mean this process of showing the maximum modulus principle tells you more about the local property of the analytic functions.

That that open sets are actually mapped open sets. So, you cannot have that the interior point is mapped on to some boundary point as a consequence of open mapping theorem; so, hence the maximum modulus principle, okay? So, let us prove this theorem using open mapping theorem. So, here is a proof belong to  $G$  then  $B(z_0, r)$  is contained in  $G$  for some  $r$  positive. If  $w_0$  is equal to  $f$  of  $z_0$ , then there is a  $\delta$  positive such that  $B(f(z_0), \delta)$  is contained in  $f$  of  $B(z_0, r)$  by the earlier theorem, which we had.

(Refer Slide Time: 35:12)

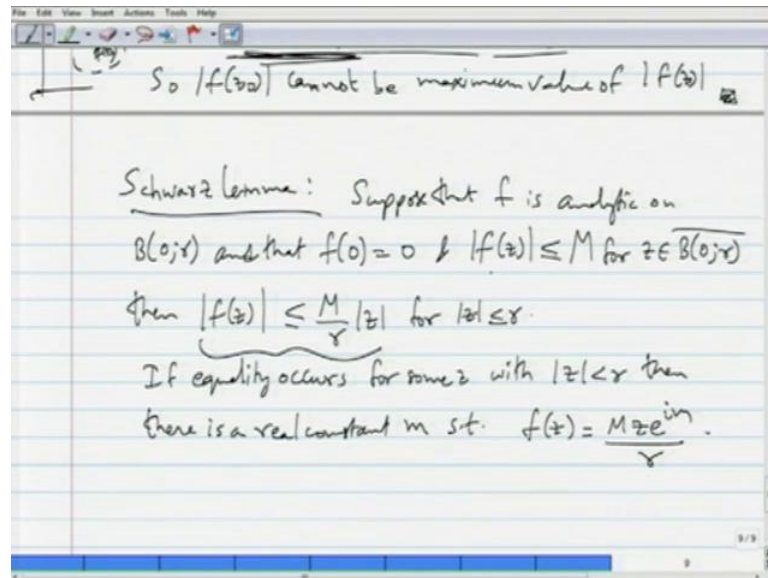

So, modulus of  $f$  of  $z_0$  clearly cannot be maximum value of modulus of  $f$  of  $z$  that is because in this ball there are always points, which have modulus greater than the modulus of  $f$  of  $z_0$ . So, in any ball the points further appear if origin is here. If  $0$  or the complex plane is here, then there are always points appear, which greater modulus than  $f$  of  $z_0$  itself. So, that is the idea. So, it proves this theorem. So, maximum modulus principle follows easily by using in the previous theorem.

Notice that, I am calling all these as a consequences of open mapping theorem, but I am desorting to a, this theorem. Well actually the hard work of the open mapping theorem is captured in this theorem. So, this is more general, but this theorem is the fundamental idea behind the open mapping theorem. So, coming back to here, now we can prove the Schwarz Lemma, which is actually a important consequence to the maximum modulus theorem, okay?

(Refer Slide Time: 36:28)

So, we can say something more about the function  $f$  and its bounds when we have more conditions as follows. The Schwarz Lemma is an application. So, here is Schwarz Lemma, so suppose that  $f$  is analytic on  $B(0; r)$  a disk of radius  $r$  centred at  $0$  and that  $f(0)$  is equal to  $0$ , okay? That and modulus of  $f$  of  $z$  is at most capital  $M$  for  $z$  belongs to  $B(0; r)$  bar. Then modulus of  $f$  of  $z$  is less than or equal to  $M$  by  $r$  modulus of  $z$  for modulus  $z$  less than or equal to  $r$ . So, if the modulus of  $f$  of  $z$  has a maximum of capital  $M$  on the one closed disk  $B(0; r)$  bar the closure of  $B(0; r)$ .

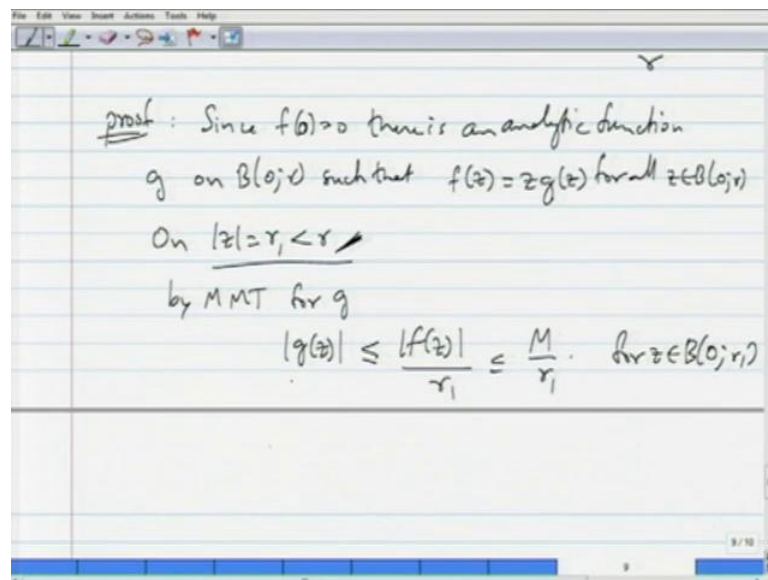

Then the modulus of  $f$  of  $z$  is at most  $m$  by  $r$  modulus  $z$ . So, before proving this let me quickly remark also that this maximum principle tells you that if  $G$  is a bounded region. If  $G$  is a bounded region, it tells you that modulus of  $f$  of  $z$  has no maximum inside in the interior of  $G$  closure. So, modulus of  $f$  of  $z$  has to have a maximum on the boundary of  $G$ , if  $G$  is bounded. Why? Well modulus of  $f$  of  $z$  firstly is a continuous function from the, from  $G$  closure into the complex plane. So, a continuous function on a compact set  $G$  I am assuming is a bounded set, okay?

So so on a compact set  $G$  closure  $f$  modulus of  $f$  has to have a maximum and the maximum cannot occur in the interior of  $G$  bar namely  $G$ . So, the the the the modulus of  $f$  has to have a maximum on the boundary whenever  $G$  is bounded. So, Schwarz Lemma is a something in that line. It is telling that if I assume that the modulus of  $f$  of  $z$  is bounded by  $M$  on, on this closed disk  $B(0; r)$  bar and  $f(0)$  we can relax that in some sense

at least for this version  $f$  of  $0$  is  $0$   $f$  is analytic on  $B(0, r)$ . Then modulus of  $f$  of  $z$  is less than or equal to  $M$  by  $r$  modulus of  $z$  for  $\text{mod } z$  less than or equal to  $r$ .

So, further actually there is more to this Lemma, we can say that if equality occurs for some  $z$  with  $\text{mod } z$  less than  $r$ . So, in this inequality if equality occurs then there is a real constant  $M$  such that  $f$  of  $z$  is actually equal to  $M z e^{i n \theta}$  by  $r$ , okay? So, it is actually the function  $M z$  by  $r$  up to some rotation  $e^{i n \theta}$  since  $f$  of  $0$  is equal to  $0$ , we have this as well, okay?

(Refer Slide Time: 40:53)

So, proof so since  $f$  of  $z$  is  $0$ . Now  $f$  of  $0$  is  $0$  there is an analytic function  $G$  on  $B(0, r)$ . Such that  $f$  of  $z$  is equal to  $z G$  of  $z$  for all  $z$  belongs  $B(0, r)$ . So, by considering the Taylor's series expansion around around  $0$ , if you wish you can say that there is a function  $G$  like that the order of  $0$  at  $0$  is at least  $1$ . So, we have this so on a  $\text{mod } z$  equals  $r_1$  strictly less than  $r$ , modulus of  $G$  of  $z$  is less than or equal...

So on a circle of radius  $r_1$  strictly less than  $r$  by using by maximum Modulus theorem for the function  $G$ , what we can say is that the modulus of  $G$  of  $z$  is less than or equal to modulus of  $f$  of  $z$  by  $r_1$ , which is less than or equal to  $M$  by  $r_1$ ; so, for for  $z$  belongs to  $B(0, r_1)$ .

(Refer Slide Time: 42:57)

Now let  $r_1 \rightarrow r$ ,  $|g(z)| \leq \frac{M}{r}$  for  $z \in B(0, r)$

$$|f(z)| \leq \frac{M}{r} |z| \quad \text{for } |z| \leq r, z \neq 0.$$

↳ for  $z=0$ , this inequality is trivially true.

$$|f(z)| \leq \frac{M}{r} |z| \quad \text{for } z \in \overline{B(0, r)}.$$

For all the  $z$  belongs to  $B(0, r)$  by maximum Modulus theorem, we have this and now letting  $r_1$  tend to  $r$  we can conclude that modulus of  $G$  of  $z$  is less than or equal to  $M/r$  for  $z$  belongs to  $B(0, r)$ . So, from this we can say that modulus of  $f$  of  $z$  is less than or equal to  $M/r$  modulus of  $z$ . By substituting what  $G$  of  $z$  is we get this. For modulus of  $z$  less than or equal to  $r$   $z$  not equal to 0, okay? Since, we are multiplying by modulus of  $z$ . And for  $z$  equals 0, this inequality is true, is trivially true, because  $f$  of 0 is 0. So, all in all Modulus of  $f$  of  $z$  is less than or equal to  $M/r$  mod  $z$  for  $z$  belongs to  $B(0, r)$ .

(Refer Slide Time: 44:08)

↳ for  $z=0$ , this inequality is trivially true.

$$|f(z)| \leq \frac{M}{r} |z| \quad \text{for } z \in \overline{B(0, r)}.$$

If  $|f(z_0)| = \frac{M|z_0|}{r}$  for some  $z_0 \in B(0, r)$  then

$|g|$  attains max at some point  $\Rightarrow g$  is a constant function so

$$f(z) = cz \quad \text{for } z \in B(0, r)$$
$$|f(z_0)| = \frac{M|z_0|}{r} \Rightarrow |c|z_0| = \frac{M|z_0|}{r} \Rightarrow$$

Now, if equality occurs if modulus of  $f$  of  $z$  happens to be equal to  $M$  mod  $z$  naught by  $r$  if  $z$  naught is equal to  $M$  mod  $z$  naught by  $r$ , for some  $z$  naught for some  $z$  naught in  $B(0, r)$ , then  $f$  attains maximum at some point, implies in inside the disk. So, implies that  $f$  is a constant function that is the only way an at an interior point, you can have a maximum modulus, so  $f$  is a constant function.

So, so  $f$  of  $z$  naught is or sorry,  $f$  of  $z$ . So,  $f$  of  $z$  looks like  $C$  times  $z$  for  $z$  belongs to  $B(0, r)$  also modulus of  $C$  modulus of  $f$  of  $z$  naught is equal to  $M$  times modulus of  $z$  naught by  $r$ , because equality occurred, which implies modulus of  $C$  times modulus of  $z$  naught is equal to  $M$  times mod  $z$  naught by  $r$ , which implies modulus of  $C$  is  $M$  by  $r$ .

The slide contains the following handwritten text and equations:

$|f|$  attains max at some point  $\Rightarrow f$  is a constant function. So

$$f(z) = cz \text{ for } z \in B(0, r)$$

$$|f(z_0)| = \frac{M|z_0|}{r} \Rightarrow |c|z_0| = \frac{M|z_0|}{r} \Rightarrow$$

$$|c| = \frac{M}{r}. \quad c = \frac{M}{r} e^{im} \text{ for some } m \text{ real}$$

So  $f(z) = \frac{M}{r} z e^{im}$  Q.E.D.

So  $C$  looks like  $M$  by  $r$  e power  $iM$  for some  $M$ . It is on  $M$  real, so  $f$  of  $z$  then is equal to  $M$  by  $r$   $z$  e power  $iM$  as claimed. So, that completes the proof of this lemma. So, we can say something more about  $f$  of  $z$ , when we know it is bound on the boundary of  $B(0, r)$  and if  $f$  of  $f$  is 0. So, that is an application of the maximum Modulus theorem.
