In this lecture

- ▶ A Mobius transformation maps circles in  $\mathbb{C} \cup \{\infty\}$  onto circles in  $\mathbb{C} \cup \{\infty\}$ .
- ▶ Orientation principle.
- ▶ Symmetry Principle.

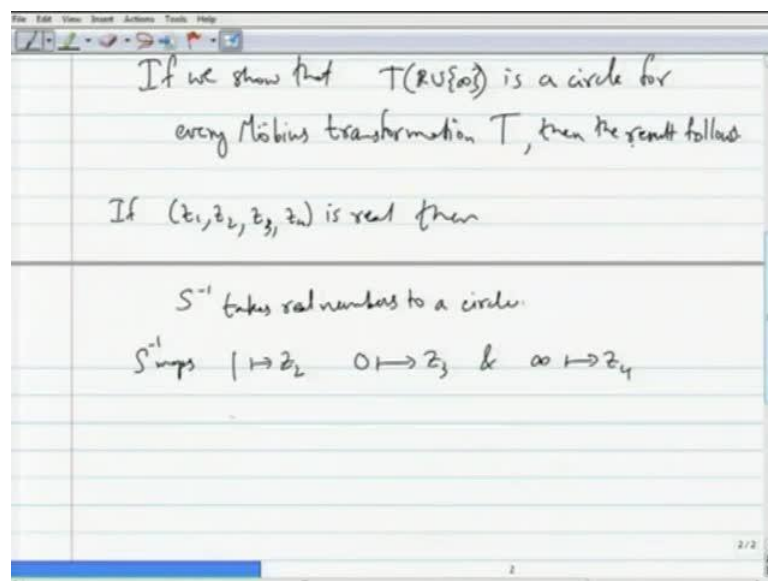

Hello viewers, in this session we will continue with the properties of Mobius transformations. So, last time we have defined the cross ratio and we have seen, how we can use the cross ratio to prove some properties of Mobius transformations? So, we will continue with that and we will show that Mobius transformations in the session, we will show that Mobius transformations take circles to circles, so images of circles on the Riemann's sphere via Mobius transformations are precisely circles; so in order to show that, we will prove the following important proposition.

(Refer Slide Time: 01:01)

So, let  $z_1, z_2, z_3$  and  $z_4$  be four distinct points in  $\mathbb{C} \cup \{\infty\}$ . Then the cross ratio  $(z_1, z_2, z_3, z_4)$  is a real number, if and only if all the four points  $z_1, z_2, z_3$  and  $z_4$  lie on a circle. So, this proposition is useful in the following sense, it tells it gives criterion in terms of the cross ratio, when four points, four distinct points lie on a circle, okay? So, here is the proof of this fact, so consider  $S$  from  $\mathbb{C} \cup \{\infty\}$  to  $\mathbb{C} \cup \{\infty\}$  defined by this cross ratio, we know that these are bijections. So, be defined by  $S$  of  $z$  is equal to  $(z, z_2, z_3, z_4)$ .

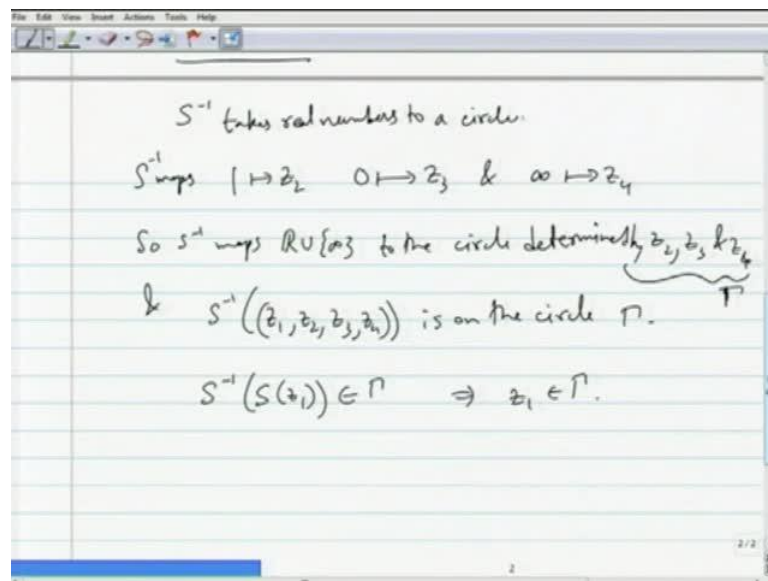

(Refer Slide Time: 03:06)

So, we will first see that if we show that,  $T$  of  $\mathbb{R} \cup \infty$  is a circle for every Möbius transformation  $T$ , then we are done then the follows. I will explain why? So, if we are able to show that the image of the  $\mathbb{R} \cup \infty$ , the real line in the complex plane union the pointed infinity is a circle, for every Möbius transformation. Circle in the sense of course, it is a circle on the Riemann's sphere, so you also includes straight lines union pointed infinity, okay?

So if the cross factor is real  $z_1, z_2, z_3, z_4$  is real then  $S^{-1}$  takes real numbers to a circle, right? So, because every Möbius transformation, so if we show that every Möbius transformation takes  $\mathbb{R} \cup \infty$  to a circle  $S^{-1}$  takes real number union infinity to a circle. In particular it takes real numbers to the, to to the circle and  $S^{-1}$  maps 1 to  $z_2$ , 0 to  $z_3$  and infinity to  $z_4$ , right? Because  $S$  maps the other way round  $z_2$  to 1  $z_3$  to 0 and  $z_4$  infinity respectively, okay?

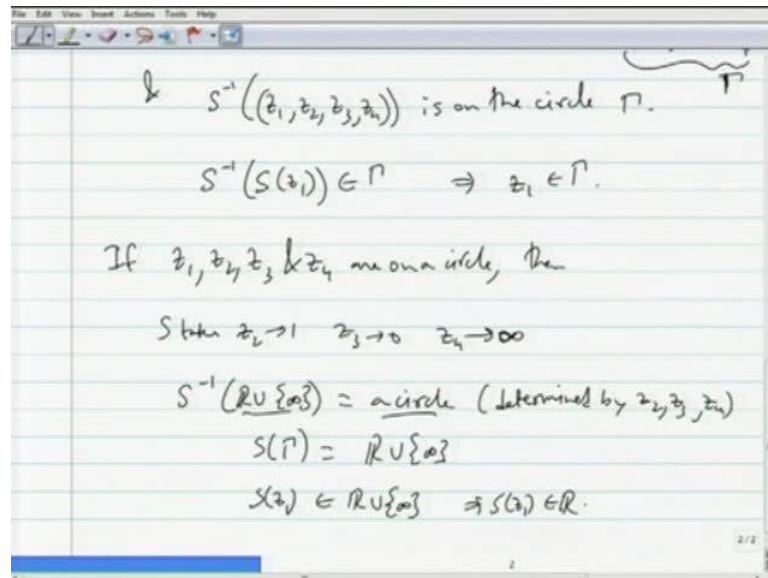

(Refer Slide Time: 05:23)

So, so  $S^{-1}$  maps you know 1 0 infinity to those points, so  $S^{-1}$  maps  $\mathbb{R} \cup \infty$ . We already assumed that it maps  $\mathbb{R} \cup \infty$  to a circle, so it maps  $\mathbb{R} \cup \infty$  to the circle determined by the three points  $z_2, z_3, z_4$ . They are distinct determined by  $z_2, z_3$  and  $z_4$  and three points always determine a circle in the complex plane union infinity.  $S^{-1}$  means the cross ratio we know is real, so  $S^{-1}$  of a this real number  $z_1, z_2, z_3, z_4$  of this real number has to be is on the circle on the circle  $\Gamma$ , where  $\Gamma$  is the circle determines by these three things.

So, let us call that gamma is on the circle gamma. So, what that means is S inverse of S of z 1, right? S of z is the cross ratio, so S inverse of S of z 1 belongs to gamma, which implies z 1 belongs to gamma. So, if the cross ratio is real and if he assume that every Mobius transformation takes R union infinity to a circle then z 1 has to be on the circle determined by z 2, z 3, z 4 which means z 2, z 3, z 4 and z 1 lie on a circle.

(Refer Slide Time: 07:08)

So, now in the other direction if z 1, z 2, z 3, z 4 are on a circle, then what we have to show is the cross ratio is a real number. Well, S takes z 2 to 1, right? Like above z 2 to 1 z 3 to 0 and z 4 to infinity, infinity. Then S inverse of R union infinity is going to be a circle like as I already circle it is going to be a circle and then it is, this is, this is determined by z 2, z 3, z 4 rather, okay? So, S of that circle S of gamma is equal to R union infinity.

So, S of z 1 which is on the circle gamma will belong to R union infinity. Well it cannot be infinity because these are distinct points and Mobius transformations are one to one functions and z 4 already goes to infinity. So, S of z 1 belongs to it is a real number, which means cross ratios are real number. So, if we assume or if we prove that T of R union infinity is a circle for every Mobius transformation T, then where so we will we will show that part here.

(Refer Slide Time: 08:46)

Let  $T(z) = \frac{az+b}{cz+d}$  & let  $z = x \in \mathbb{R}$  &  $w = T^{-1}(z)$

then  $x = T(w) \Rightarrow T(w) = \overline{T(w)}$

$$\frac{aw+b}{cw+d} = \frac{\bar{a}\bar{w}+\bar{b}}{\bar{c}\bar{w}+\bar{d}}$$

So let, let  $T$  of  $z$  be  $a z$  plus  $b$  divided by  $C z$  plus  $b$ , it is a Möbius transformation and let  $z$  equals  $x$  belongs to  $\mathbb{R}$ . So, we will we can treat infinity separately. So, let us say  $x \in \mathbb{R}$  and  $w$  is  $S T$  inverse of  $x$ . Then  $x$  is equal to  $T w$ , which implies  $T$  of  $w$   $T w$  or  $T$  of  $w$  is equal to its own conjugate, because it is a real number.  $x$  is a real number, so  $T$  is equal to its own conjugate  $T$  of  $w$  is equal to conjugate. So, let us write down what that means  $a w$  plus  $b$  divided by  $a C w$  plus  $d$  is equal to  $a$  bar  $w$  bar plus  $b$  bar divided by  $C$  bar  $w$  bar plus  $d$  bar by the properties via the properties of conjugation.

(Refer Slide Time: 10:11)

$$\frac{aw+b}{cw+d} = \frac{\bar{a}\bar{w}+\bar{b}}{\bar{c}\bar{w}+\bar{d}}$$

$$(a\bar{c} - \bar{a}c)|w|^2 + (a\bar{d} - \bar{b}c)w + (b\bar{c} - \bar{d}a)\bar{w} + (b\bar{d} - \bar{b}d) = 0 (*)$$

If  $a\bar{c}$  is real then  $a\bar{c} - \bar{a}c = 0$ .

Let  $\alpha = 2(a\bar{d} - \bar{b}c)$  & let  $\beta = i(b\bar{d} - \bar{b}d)$

From  $\frac{\alpha}{2}w + \frac{\bar{\alpha}}{2}\bar{w} + \frac{\beta}{i} = 0$

So, after rearrangement this gives us  $\bar{c} - \bar{a} C$  modulus of  $w$  square plus  $\bar{d} - \bar{b} c$  times  $w$  plus  $b C - d a$  times  $\bar{w}$  plus  $b d - \bar{b} d$  is equal to 0. So, let us call this equation star looking at this equation, what we want to show is that  $w$  is a point on the circle. So, the locus of  $w$  it satisfies this equation is actually a circle, so we are actually showing this statement  $T$  of  $R \cup \infty$  is a circle by showing that  $T^{-1}$  of  $R \cup \infty$  is a circle for every Mobius transformation  $T$ . But since every Mobius transformation is an inverse of yet another Mobius transformation, we get the result we get the result that we desire.

So, firstly there are two cases to consider if  $\bar{c}$  is real this is the first case then,  $\bar{c}$  will be equal to  $a \bar{c}$ . It will be equal to its own conjugate. So, in this case then  $\bar{c} - \bar{a} c$  is equal to 0. So, this coefficient here is going to be 0, so in this event we observe that we have conjugates here. So, 1 is the conjugate of the other two terms, which are conjugate to each other. So, let  $\alpha = 2(\bar{d} - \bar{b} c)$ , that 2 is just to avoid a multiple of 2. We will see in a moment and let  $\beta = i(b d - \bar{b} d)$ .

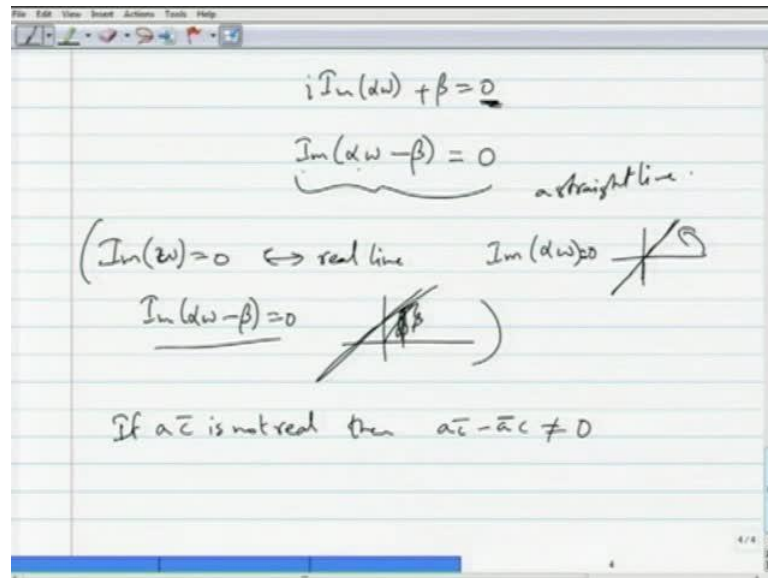

So, once again I have multiplied that by an  $i$  to put this other term here in a nice form. But notice that this number is a difference of conjugates. So, that gives an purely imaginary number, so it gives the imaginary part of  $b d - \bar{b} d$  two times that, so that is that is imaginary number. So,  $\beta$  here is a real number, so then what we get by substituting  $\alpha$  and  $\beta$  like this. What we get is  $\alpha w^2 + \alpha \bar{w} + \beta = 0$ .

(Refer Slide Time: 13:06)

$$i \frac{\alpha w - i \bar{\alpha} \bar{w}}{2} + \beta = 0$$
$$i (\alpha w - \bar{\alpha} \bar{w}) + \beta = 0$$
$$\frac{i}{2} 2 \operatorname{Im}(\alpha w) + \beta = 0$$
$$i \operatorname{Im}(\alpha w) + \beta = 0$$
$$\operatorname{Im}(\alpha w - \beta) = 0$$

So, then I will multiply by  $i$  to get  $i$  times  $\alpha w$  plus  $\bar{\alpha} \bar{w}$  plus  $2\beta$  is equal to  $0$ . I apologise this should be a minus this is  $b c \bar{b} - \bar{b} a$ , which is minus of this. So, I will remove this underlines, so this is a minus  $\bar{\alpha} \bar{w}$  this is a minus and then I get  $\alpha w - \bar{\alpha} \bar{w}$ . Then I had an  $i$  here, I had to multiply an  $i$  here  $i$  by  $2$  times all this plus  $\beta$  is equal to  $0$ . Then  $\alpha w - \bar{\alpha} \bar{w}$  is  $2$  times the imaginary part of  $\alpha w$  times  $i$  by  $2$  plus  $\beta$  is equal to  $0$ . This is  $i$  times the imaginary part of  $\alpha w$  plus  $\beta$  is equal to  $0$ . So, so we can sum these up by saying imaginary part of  $\alpha w - \beta$ . So, by equating the real parts we have that is equal to  $0$ . So, we recognise this as I mean the locus of these points is a line, right?

(Refer Slide Time: 14:36)

Imaginary part recall from section of geometry, we said that imaginary part of  $w$  is equal to 0 gives us real line and likewise imaginary part of  $\alpha w$ . What it gives is, it is a line passing through origin of that sort  $a$  is equal to 0 and imaginary part of  $\alpha w$  minus  $\beta$  is equal to 0, which gives a line which is that sort everything is transferred by a vector  $\beta$ , okay?

So, that is  $\beta$ . So, every point is moved by a vector  $\beta$  and here you multiply by number  $\alpha$ . So, the real line actually turns and then  $\alpha w$  minus  $\beta$  will transfer the line by  $\beta$ . That signifies a straight line, so the locus here is a straight line. So, in the event that  $a\bar{c}$  is real what we have is a straight line, so in the other case, if  $a\bar{c}$  is not real if  $a\bar{c}$  is not real in the coefficient of  $\text{mod } w^2$  in in star is not 0. Then then  $a\bar{c} - \bar{a}c$  is not equal to 0, so that is the point.

(Refer Slide Time: 16:21)

$\text{Im}(dw - \beta) = 0$

If  $a\bar{c}$  is not real then  $a\bar{c} - \bar{a}c \neq 0$

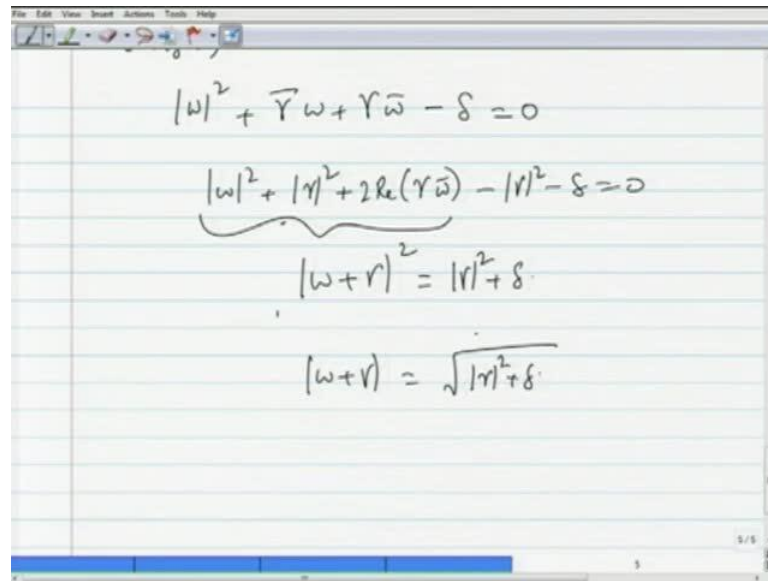

Let  $\gamma = \frac{a\bar{d} - \bar{b}c}{a\bar{c} - \bar{a}c}$  & let  $\delta = \frac{\bar{b}d - b\bar{d}}{a\bar{c} - \bar{a}c}$  ( $\delta$  is real)

Using (\*)

So, then that let gamma be a d bar minus b bar c divided by a c bar minus a bar c. So, we can now divide a c bar minus a bar c and let delta be equal to b bar d minus b d bar divided by a c bar minus a bar c. So, then notice that delta is a real quantity because the numerator is a purely imaginary quantity it is two times the imaginary part of certain complex number and likewise the denominator is a purely imaginary quantity.

So, i s cancel as the two cancel etcetera so you have a real quantity. So, delta is real, so real number and then by letting this and substituting this star using star what we have is let me go back to star, sorry so this is I am dividing equations star by a c bar minus a bar c. Then the coefficient of w and w bar show up something in terms of gamma because i am dividing by a c bar minus a bar c, so that is the coefficient and this last coefficient this last constant will be in terms of delta.

(Refer Slide Time: 18:05)

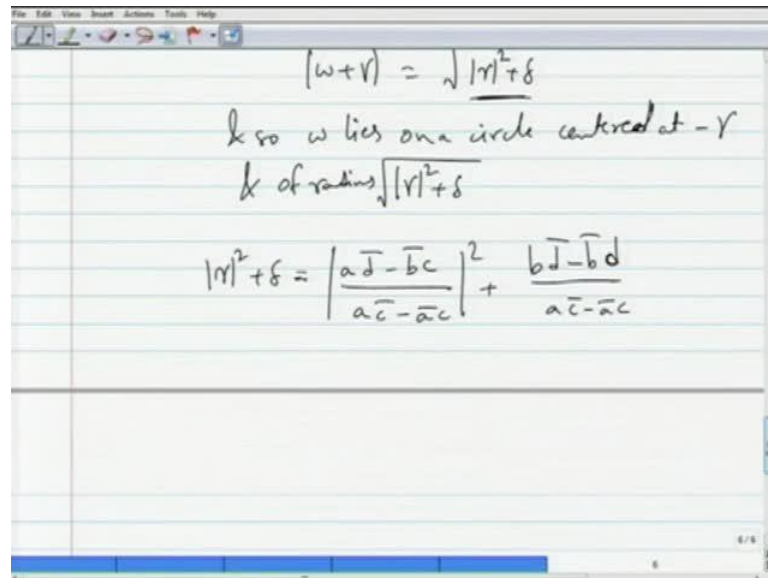

The image shows a digital whiteboard with a toolbar at the top. The whiteboard contains the following handwritten mathematical steps:

$$|w|^2 + \bar{\gamma}w + \gamma\bar{w} - \delta = 0$$
$$|w|^2 + |\gamma|^2 + 2\operatorname{Re}(\gamma\bar{w}) - |\gamma|^2 - \delta = 0$$
$$|w + \gamma|^2 = |\gamma|^2 + \delta$$
$$|w + \gamma| = \sqrt{|\gamma|^2 + \delta}$$

So, what I get is, I have modulus of  $w$  square plus  $\gamma$  bar  $w$  minus  $\gamma w$  bar like we observed earlier. These are conjugates of each other, these two terms are conjugates of each other and then finally, I have minus  $\delta$  is equal to 0. The way I have assumed  $\delta$  is  $b$  bar  $d$  minus  $b d$  bar that is the negative of what I have there, we will see why in a moment, okay? So, then this is the same as modulus of  $w$  square plus modulus of  $\gamma$  square. I am adding a modulus of  $\gamma$  square and these are conjugates of each other.

So, when I add them, I get 2 times real part of  $\gamma w$  bar. Then, minus modulus of  $\gamma$  square I have added a modulus of  $\gamma$  square there. So, I get that minus  $\delta$  is equal to 0, so this we recognise the modulus of  $w$  plus  $\gamma$  whole square. That equals modulus of  $\gamma$  square plus  $\delta$  and modulus of  $\gamma$  square is a real number plus  $\delta$  is a real number. So, this looks like the equation of a circle, so this is modulus of  $w$  plus  $\gamma$ . I will take this part is equal to square root of modulus of  $\gamma$  square plus  $\delta$  it is a positive real number we will show, okay? So, one can check, okay?

(Refer Slide Time: 19:48)

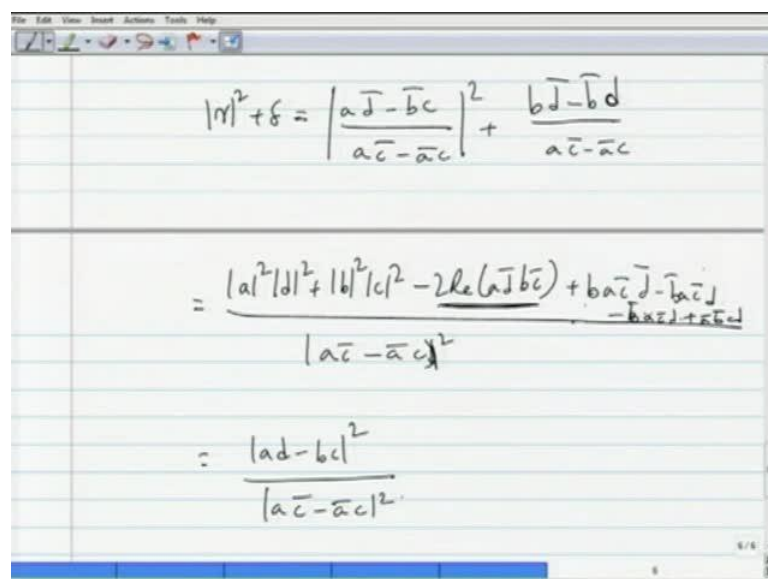

$$|w+\gamma| = \sqrt{|\gamma|^2 + \delta}$$

So  $w$  lies on a circle centred at  $-\gamma$   
& of radius  $\sqrt{|\gamma|^2 + \delta}$

$$|\gamma|^2 + \delta = \left| \frac{a\bar{d} - \bar{b}c}{a\bar{c} - \bar{a}c} \right|^2 + \frac{b\bar{d} - \bar{b}d}{a\bar{c} - \bar{a}c}$$

So,  $w$  lies on a circle centred at minus gamma and of radius modulus gamma square plus delta square root. So, only if modulus of gamma square plus delta is a positive real number, but that is easy so you can check that modulus of gamma square plus delta. Well that is equal to modulus of  $a\bar{d} - \bar{b}c$  divided by  $a\bar{c} - \bar{a}c$  whole squared plus delta modulus of delta. Well, delta is  $b\bar{d} - \bar{b}d$  divided by  $a\bar{c} - \bar{a}c$ , when I take the common denominator.

(Refer Slide Time: 20:57)

$$|\gamma|^2 + \delta = \left| \frac{a\bar{d} - \bar{b}c}{a\bar{c} - \bar{a}c} \right|^2 + \frac{b\bar{d} - \bar{b}d}{a\bar{c} - \bar{a}c}$$

$$= \frac{|a|^2|d|^2 + |b|^2|c|^2 - 2\operatorname{Re}(a\bar{d}\bar{b}c) + b\bar{a}\bar{c}\bar{d} - \bar{b}a\bar{c}d}{|a\bar{c} - \bar{a}c|^2}$$

$$= \frac{|ad - bc|^2}{|a\bar{c} - \bar{a}c|^2}$$

What I have is modulus of a square modulus of d square plus modulus of b square modulus of c square minus two times the real part of a d bar minus b bar c a d bar minus c b b c bar rather. Then divided by modulus of a c bar minus a bar c square plus b ad bar so we can actually directly add this, okay? So, I get plus b a c bar d bar etcetera of minus b bar a c bar d minus b a bar c bar d plus a bar b bar, so this two times real part of a d bar b c bar cancels with this plus this.

So, this I mean terms with the plus sign in front of them that cancels with that b bar and then the terms with the minus sign in front of them they remain. That gives me modulus of a d minus b c that gives me that divide by modulus of a c bar minus a bar c square, okay?

(Refer Slide Time: 22:38)

$$= \frac{|ad - bc|^2}{|a\bar{c} - \bar{a}c|^2}$$

$$\sqrt{|r|^2 + \delta} = \left| \frac{ad - bc}{a\bar{c} - \bar{a}c} \right| > 0.$$

Locus of  $w$  is a circle in either case

So locus of  $T^{-1}(x)$  is a circle. So  $T^{-1}$  takes  $\mathbb{R} \cup \{\infty\}$  to a circle

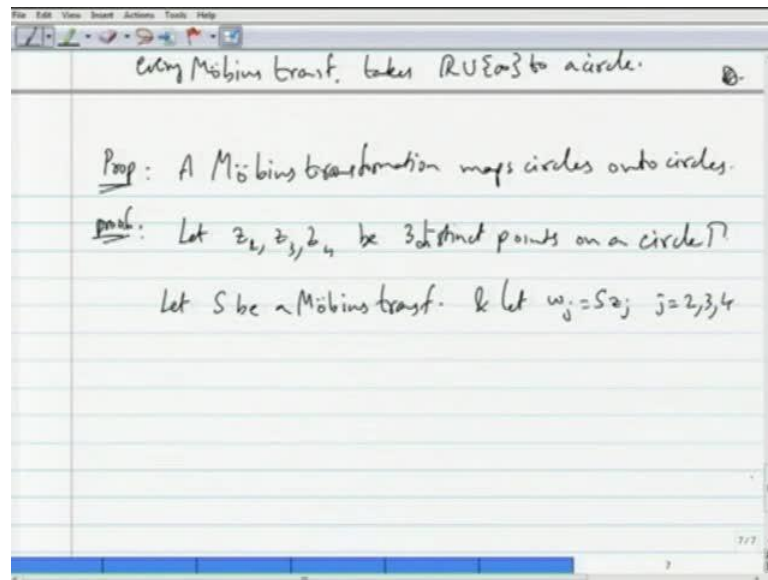

Since every Möbius transf. is the inverse of some Möb transf.

So, the square root of modulus gamma square plus delta is equal to modulus of a d minus b c by a c bar minus a bar c which is a positive quantity. So, that shows that T inverse in in either of these two cases, what we have shown is that locus of w according to star the locus of w. According to star is a circle, so locus of w is a circle in either case it is a generalised circle on the Reimann's sphere. So, you have straight line from the complex plane in an infinity or you have a circles is a circle.

So, T inverse takes r union infinity to a circle since, there was no assumption about x the real number x t inverse of r union infinity is a circle. Since, every Mobius transformation is inverse of some Mobius transformation, it is through that the image of R union infinity

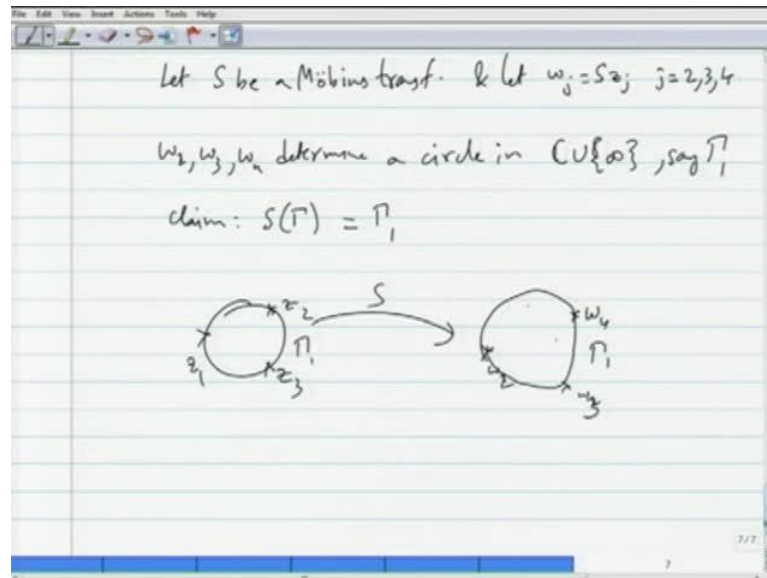

is a circle for Möbius transformation. So, since every Möbius transformation is the inverse of some Möbius transformation and every inverse has this property every Möbius transformation takes  $\mathbb{R} \cup \infty$  to a circle and that completes the proof of this proposition.

(Refer Slide Time: 24:35)

Next, we will show the following proposition based on this one which we have been aiming at a Möbius transformation maps circles on to circles. Now, this is easy or it follows easily from the previous proposition. So, let  $z_1, z_2$  or  $z_2, z_3, z_4$  be three distinct points on a given circle on a circle  $\gamma$ . So, let  $S$  be Möbius transformation, so you take the general Möbius transformation and let  $w_j$  I will just say  $w_j$  is equal to  $Sz_j$  for  $j$  is equal to  $2, 3, 4$ . So, let  $w_j$  be the image of  $z_2, z_3, z_4$  or  $z_j$  in under  $S$ , okay?

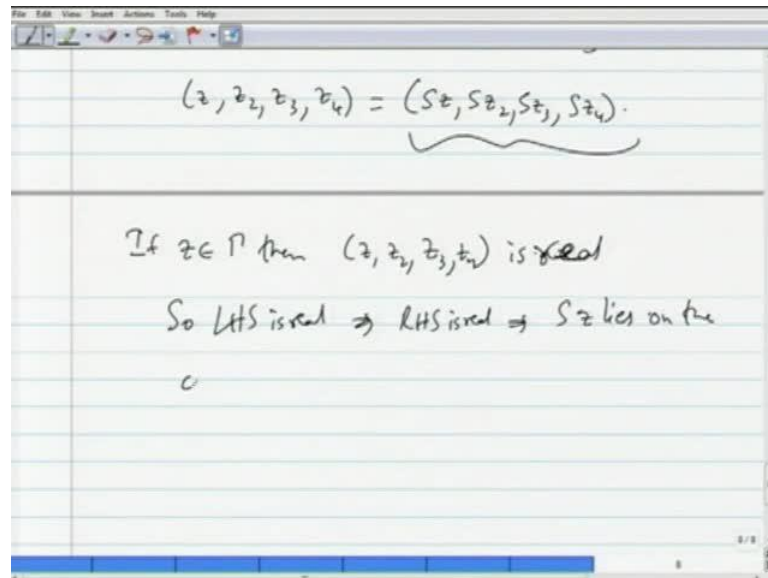

(Refer Slide Time: 26:29)

Now,  $w_2, w_3, w_4$  determine a circle any three points. Determine a circle these  $w_2, w_3, w_4$  they have to be distinguished because  $z_2, z_3, z_4$  were distinct. So, and  $S$  is a Möbius transformation, so these determine a circle in  $\mathbb{C} \cup \{\infty\}$ . We will call that say  $\Gamma_1$ . So, we will claim the, claim is that  $S$  maps, so  $S$  for now maps three points  $z_2, z_3, z_4$  to  $w_2, w_3, w_4$ . There is a circle determined by  $z_2, z_3, z_4$  and 1 by  $w_2, w_3, w_4$ , okay?

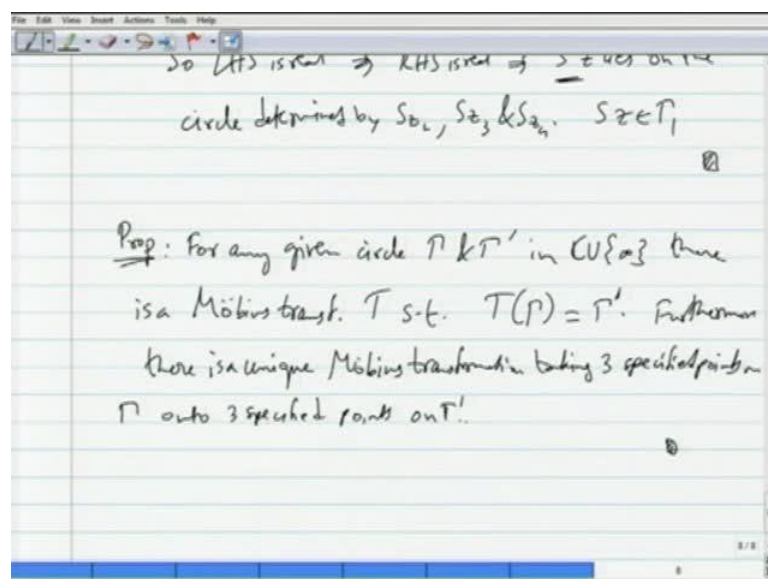

So, the claim now is that  $f$  takes all of  $\Gamma$  on to  $\Gamma_1$ . So, here is  $z_1, z_2$  and  $z_3$  on a circle and then all we know is that the image of these three points is  $w_1, w_2, w_3$  or  $w_2, w_3, w_4$  and there is a circle which passes through these three  $\Gamma$ . One the claim is that  $s$  maps exactly the circle under that circle now the proof is very easy using that other proposition.

(Refer Slide Time: 28:01)

The cross ratio  $z, z_2, z_3, z_4$  is equal to cross ratio  $Sz, Sz_2, Sz_3$  and  $Sz_4$  by a previous proposition. We saw this, this tells us that if  $z$  belongs to  $\Gamma$ , then by the previous proposition this cross ratio  $z, z_2, z_3, z_4$  is a point on the circle determined by  $z_2, z_3, z_4$ . So, this is real, is a real number. This is real and so LHS is real, so this number is also a real number. What that tells is that implies RHS is real and what that implies is  $Sz$  lies by the previous proposition  $Sz$  lies on the circle.

(Refer Slide Time: 29:11)

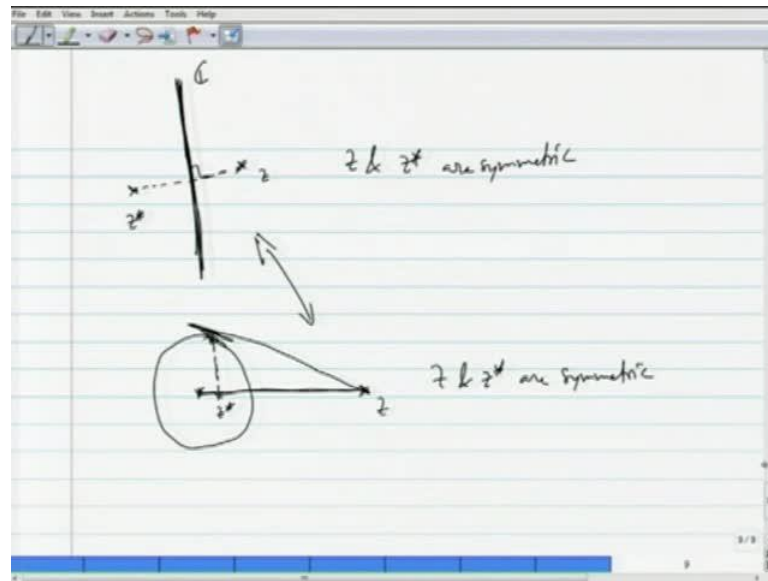

Determined by  $S z 2$ ,  $S z 3$  and  $S z 4$ , so  $S z$  belongs to  $\gamma_1$ , so that completes the proof of this proposition. So, it follows directly from the previous proposition. Now, then we can also do the following for any given circles  $\gamma$  and  $\gamma_1$  or  $\gamma$  prime. Let us say in  $\mathbb{C} \cup \infty$ , there is a Möbius transformation that is easy Möbius transformation,  $T$  such that  $T$  of  $\gamma$  is equal to  $\gamma_1$  prime, okay? Furthermore, there is a unique Möbius transformation taking three specified points on  $\gamma$  on  $\gamma_1$  onto three specified points.

These points have to be distinct, distinct points on  $\gamma_1$  prime. The proof is it just follows from what we have done already. So, the proof is an exercise for the viewer. It just follows from what we have done, so given three points from the circle and then three point from that circle that is unique Möbius transformation, which takes these three points to those three points. Well if you give a circle, there are many ways to specify circle as an by many triples of points specify this circle.

So, if you want a circle to be mapped on to another circle, there are many Möbius transformations doing the job. So, that is this proposition. What we have shown, so far is that circles on  $\mathbb{C} \cup \infty$  on the Riemann's sphere are actually mapped onto circles via Möbius transformations. So, we will rough roughly state some theorems, which will tell us that the inside and outside of the circles all are also mapped onto inside and outside of circles, via Möbius transformation. So, we will make that notion a little concrete, okay? So, firstly let me make a diagram like this, okay?

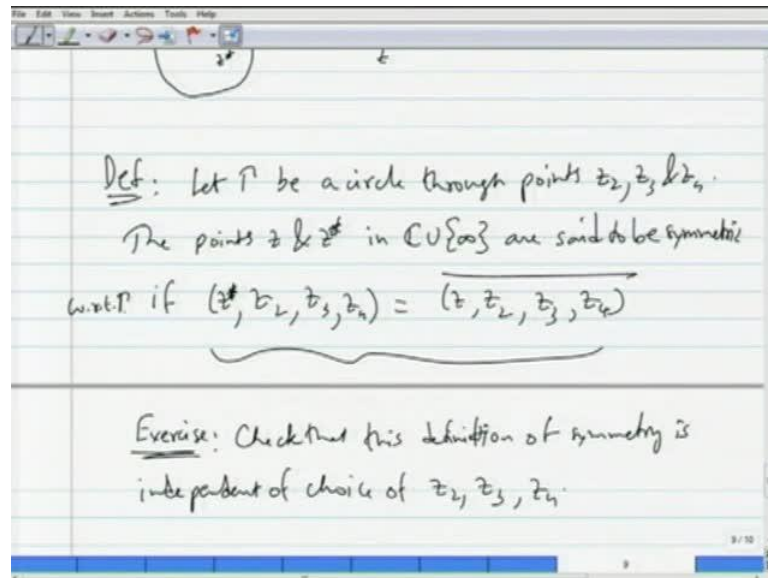

(Refer Slide Time: 32:20)

So, the point  $z$  here is a straight line in  $\mathbb{C}$  union infinity or a circle in  $\mathbb{C}$  union infinity, which is a straight line in the complex plane. So, if you have a point  $z$  from high school geometry we know that where we call a point  $z^*$  symmetric to  $z$  with respect to this line. If the line joining  $z$   $z^*$  is perpendicularly bisected by this one, so  $z$  and  $z^*$  we call a symmetric and there is a similar notion, when it comes to circles. So, this notion actually transfers to circle from the Riemann's sphere you take a point, which is outside the circle here is  $z$  should draw tangent from the circle to the point to the circle. You drop a perpendicular onto the line joining  $z$  in the centre of the circle and this point  $z^*$  that you get is called symmetric. So, this is a notion, which equates to this notion for a straight line, when you look at it on the complex on the on the Reimann's sphere.

(Refer Slide Time: 33:56)

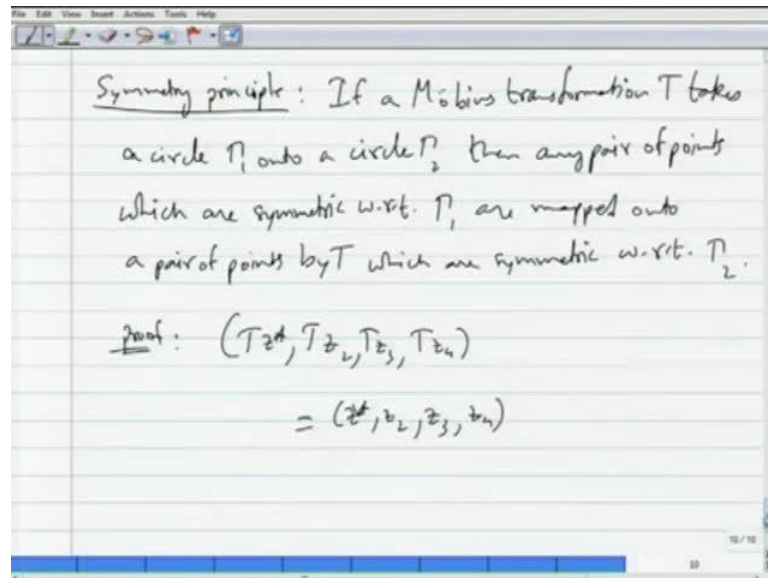

So,  $z$  and  $z^*$  then are called symmetric and when we write in the language of cross ratio we have the following definition. So, let  $\gamma$  be a circle through points  $z_2, z_3$  and  $z_4$  the points  $z$  and  $z^*$  in  $\mathbb{C} \cup \{\infty\}$  are said to be symmetric. If  $(z^*, z_2, z_3, z_4)$  is equal to  $\overline{(z, z_2, z_3, z_4)}$  conjugate of this is equal to the cross ratio with  $z^*$ , okay?

So, in the, this is essentially the symmetry the geometric symmetry. Here in the language of cross ratio and the equivalence of this is proved in the textbook. I am following for this discussion namely in John Conway's book functions of one complex variable. So, interested viewer can actually work this out as an exercise or look into the book. One one thing that one should observe is that check that here  $z_2, z_3, z_4$  determine a circle and I am defining symmetry apparently by choosing a particular  $z_2, z_3, z_4$  on the circle. So, check that this definition of symmetry is independent of the choice of  $z_2, z_3, z_4$ , okay?

So, in the definition I should say said to be symmetric with respect to  $\gamma$  that is important, sorry for that so, this is are said to be symmetric with respect to  $\gamma$ . If that happens there are other ways of specifying  $\gamma$ . You can take other  $z_2, z_3, z_4$ . So, if you take  $z_2'$   $z_3'$  and  $z_4'$ , try to show that this equalities will holds if it holds for  $z_2, z_3, z_4$ , okay?

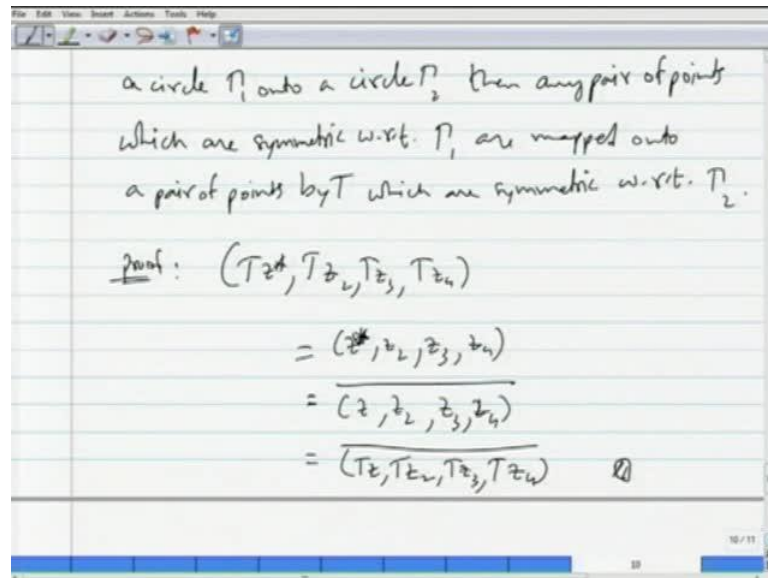

(Refer Slide Time: 36:51)

So, then I am going to state what happens to points inside and outside of a circle via a Möbius transformation, via the mapping this is the Möbius transformation, okay? So, here is symmetric principle I will not prove this, but I will just state this if a Möbius transformation  $T$  takes a circle  $\gamma_1$  onto a circle  $\gamma_2$ . Then any pair of points which are symmetric with respect to  $\gamma_1$  are mapped onto a pair of points by  $T$ . They are mapped onto two points by  $T$ , which are symmetric with respect to  $\gamma_2$ . So, the image of a circle is a circle and image of two points are symmetric with respect to the initial circle are now symmetric with respect to the image circle via  $T$ .

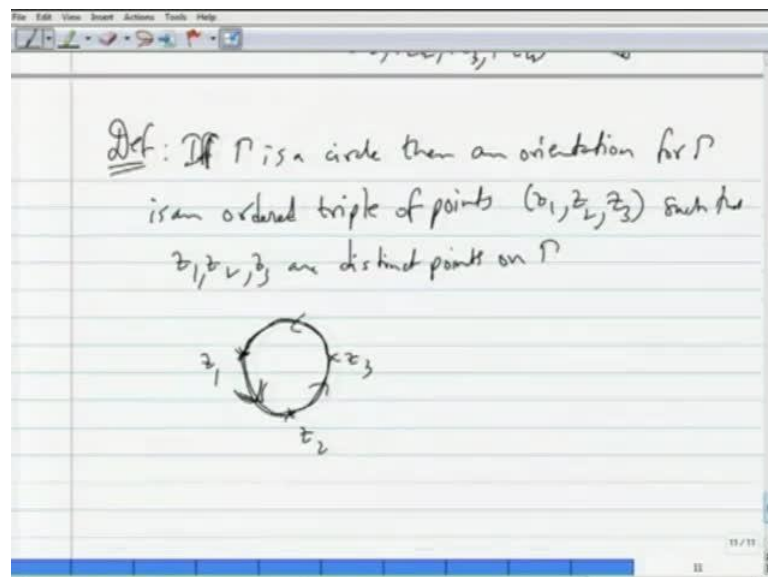

So, that is the picture we have and the proof is it is very easy. So,  $Tz^*$ ,  $Tz_2$ ,  $Tz_3$ ,  $Tz_4$ , that is going to be we have to show that this is equal to  $Tz$ ,  $Tz_2$ ,  $Tz_3$ ,  $Tz_4$  conjugate, but this is equal to  $z^*$ ,  $z_2$ ,  $z_3$ ,  $z_4$  via property, we had earlier that the cross ratio remains invariant under when all the points are moved via Möbius transformation.

(Refer Slide Time: 39:01)

This is equal to  $z, z_2, Tz_3, Tz_4$  because  $z^*$  and  $z$  are symmetric with respect to  $\Gamma_1$ . That is equal to once again by invariance by  $r$  Mobius transformation. We have  $Tz, Tz_2, Tz_3, Tz_4$  conjugate, okay? So, since  $z, z_2, z_3, z_4$  is equal to the cross ratio  $Tz, Tz_2, Tz_3, Tz_4$ , so it completes, okay?

(Refer Slide Time: 39:39)

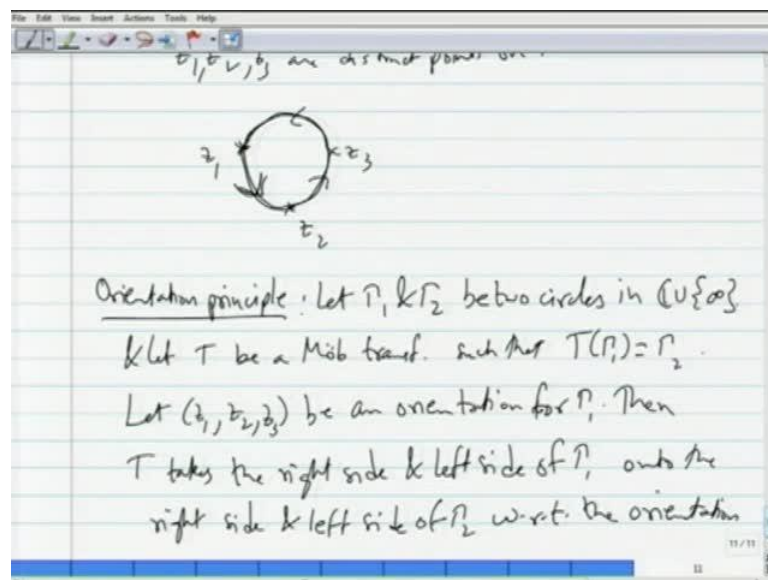

So, then we are going to make a definition of orientation. Now, well if you have a circle its stays unoriented, but in order to identify the inside and outside we will orient the circle first. So, if  $\Gamma$  is a circle, if  $\Gamma$  is a circle, then orientation for  $\Gamma$

is an ordered example of points  $z_1, z_2, z_3$ . This is an ordered triple such that  $z_1, z_2, z_3$  are distinct points on  $\gamma$ .

So, what you are doing is you are picking three points  $z_1, z_2, z_3$  on a circle and specifying them as an ordered triple. So, the order tells you that you go from  $z_1$ , to  $z_2$  and then  $z_2$  to  $z_3$  and come back to  $z_1$ . So, that specifies a particular order, when  $z_1, z_2, z_3$  are distinct. So, it specifies an orientation on that circle and when you imagine walking on that circle in the complex plane or in  $\mathbb{C} \cup \infty$ . So, with your head up, so to say then you have a region to the left and you have a region to the right. Then what we have is the following we have the orientation principle.

(Refer Slide Time: 41:35)

So, let  $\gamma_1$  and  $\gamma_2$  be two circles in  $\mathbb{C} \cup \infty$ . So, let  $T$  be a Möbius transformation such that  $T$  of  $\gamma_1$  is equal to  $\gamma_2$ . Let  $z_1, z_2, z_3$  be an ordered triple be an orientation of  $\gamma_1$  or for  $\gamma_1$ . Then  $T$  takes the right side and left side of  $\gamma_1$ . Onto the right side and left side of  $\gamma_2$  with respect to orientation the orientation of  $\gamma_2$  given by  $Tz_1, Tz_2, Tz_3$ .

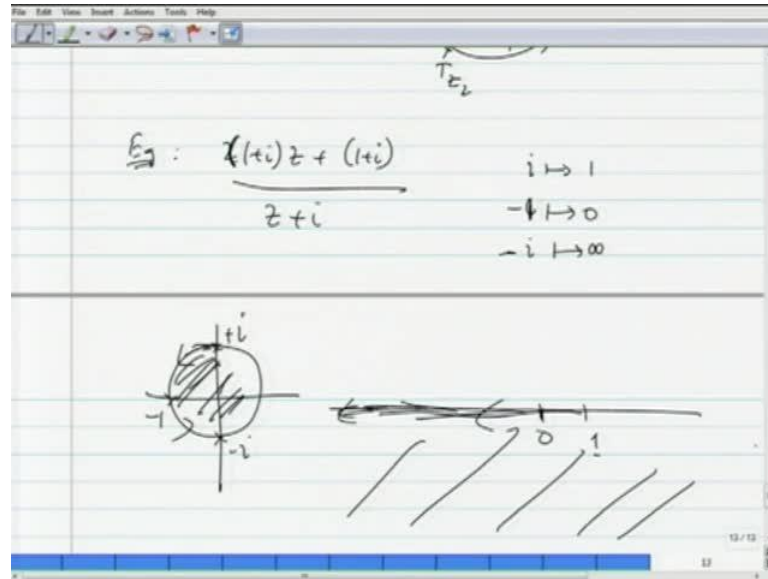

(Refer Slide Time: 42:58)

So, a circle can be mapped onto, so you pick a circle with a orientation  $z_1, z_2, z_3$ , okay? It can be mapped onto a circle in two ways looking at the orientation it could be  $Tz_1, Tz_2, Tz_3$  or you could have a circle  $Tz_1, Tz_2, Tz_3$ . So, it depends upon the Möbius transformation this circle will give you, sorry this kind of orientation and this circle will give you this kind of orientation. So, there are two ways two different orientation used on the same circle.

That orientation depends on  $T$  and this orientation principle which we are which we are stating here without proof that tells you that the left side here. For example, this is the left side on on this, in this picture that is mapped onto the left side. Here in this case the left side happens to be outside of this circle and in this case it happens to be inside of the circle, okay? The left sidedness and right sidedness are preserved by Möbius transformation and that is stated by the orientation principle. So, once again for rigorous proofs one can consult convey.

(Refer Slide Time: 44:45)

So, here is a quick example, the transformation  $1 + i$  times  $z$  plus  $1 + i$  divided by  $z + i$ , this is the Möbius transformation. It takes it maps  $i$  to  $1$  minus  $1$  to  $0$  and, and  $i$  to infinity or minus  $i$  to infinity. It maps so, it maps the unit circle here is the minus  $i$  and minus  $1$  sorry, here is plus  $i$  here is minus  $1$  and here is minus  $i$ , it maps them to  $1$ ,  $0$  and infinity.

So, infinity is direction, think of it in this direction. So, it maps this circle onto this line in this direction with that orientation. So, what it does is it maps the unit disc, which appears to the left of the circle now onto the lower half. So, that is an example, so we will conclude this discussion on Möbius transformations with this example. I will stop.
