**Removable Singularities**

Hello viewers, in this session, we will learn about the singularities in particular isolated singularities of an, of an analytic function. So, firstly a point in the complex plane, where a function  $f$  is analytic is called a regular point. So, a singularity is such a point, where  $f$  is not defined, so of particular interest are singular points, which are surrounded by points, which are regular or in other words if there is a point  $a$ , such that in the neighborhood of  $a$   $f$  is analytic. Then such a point is said to be a singularity, isolated singularity of  $f$  and we are interested in predicting the, the behavior of  $f$ . Then around this point are using the behavior of  $f$  around this point in order to classify such isolated singularities. So, I will first define a regular point and a singular point.

(Refer Slide Time: 01:33)

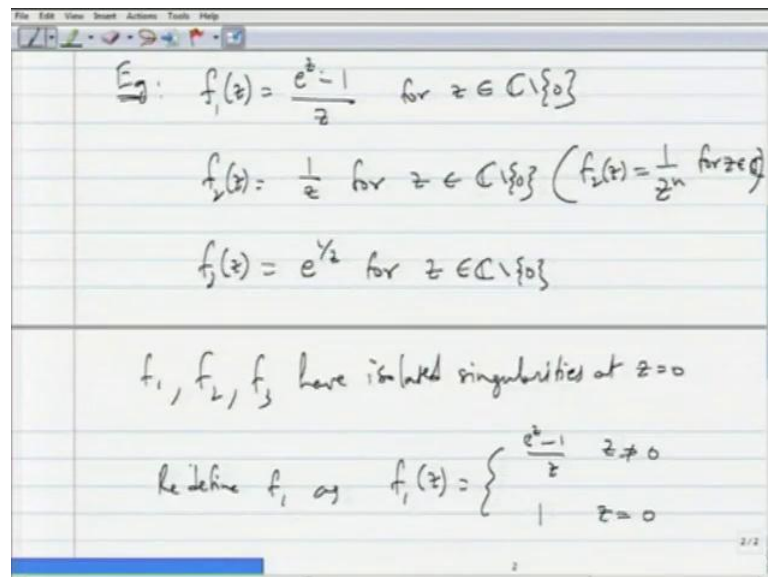

So, a regular point we say that  $a$  belongs to  $\mathbb{C}$  is a regular point of a function  $f$ . If  $f$  is a analytic at  $a$ , and a point  $a$  is called a singularity of  $a$  of  $f$  rather called a singularity of  $f$ . If  $a$  is a limit point of regular points of  $f$ , so that is a singular. So, suppose  $f$  is analytic on  $B$  prime  $a$   $r$ , then we say that  $f$  have an isolated singularity, at  $a$  ok. So, the first trivial

case is the case, where  $f$  is actually analytic at  $a$ . So, it is  $a$ , it is analytic in  $B$  prime  $a$  r recall  $B$  prime  $a$  r is the deleted neighborhood of  $a$ .

So, we are removing  $a$  from the ball of radius  $r$  around  $a$ . If  $f$  is analytic in this punctured neighborhood or deleted neighborhood it could happen that actually  $f$  is analytic at  $a$ , but we did not define it there, that is all. So, in that event we say that such a point is a removable singularity of  $f$  at  $a$  and there are other cases, but first this, this is I mean first this is the trivial case, which we will consider and then we will classify other kinds of behavior of  $f$  around  $a$ .

(Refer Slide Time: 04:09)

So, firstly I'll start by giving some examples, so consider these functions  $f_1$  of  $z$  defined by  $e^z - 1$  divided by  $z$  for  $z$  belongs to  $\mathbb{C}$  and  $f_2$  of  $z$ . So, firstly I will complete these three examples and  $f_2$  of  $z$  is  $1/z$  for  $z$  belongs to  $\mathbb{C}$ . One can actually consider  $f_2$  of  $z$  equals  $1/z^n$  for  $z$  belongs to  $\mathbb{C}$ ,  $n$  is any integer for  $z$  belongs to  $\mathbb{C}$ , okay?  $f_3$  of  $z$  is equal to  $e^{1/z}$  for  $z$  belongs to  $\mathbb{C}$ . I apologize  $\mathbb{C} \setminus \{0\}$  at  $0$  at this function is not defined, so  $\mathbb{C} \setminus \{0\}$  and even this is  $\mathbb{C} \setminus \{0\}$ .

All these are functions on  $\mathbb{C} \setminus \{0\}$ , so all these have singularities at the point  $0$ . So,  $f_1, f_2, f_3$  have isolated singularities at  $0$  at  $z$  equals  $0$ . And we could I mean  $f_1$  could be redefined to be, so these are three different kinds of isolated singularities as we will see.  $f_1$  could be redefined as  $f_1$  of  $z$ , so let us redefine  $f_1$ . As  $f_1$  of  $z$  is whatever it is given to be  $e^z - 1$  by  $z$  for  $z$  not equal to  $0$  and let us define it to be  $1$  for  $z$  equals

0. So, since we know that the limit as  $z$  goes to 0 of this quantity  $e^z - 1$  by  $z$  is actually equal to 1. So, that limit is 1, so if you redefine  $f_1$  to be 1 at 0, then  $f_1$  is actually analytic.

(Refer Slide Time: 06:40)

re define  $f_1$  as  $f_1(z) = \begin{cases} z & z \neq 0 \\ 1 & z = 0 \end{cases}$   
 Then  $f_1$  is analytic on  $\mathbb{C}$ .  
 $f_2(z) \rightarrow \infty$  as  $z \rightarrow 0$ .  
 $\lim_{z \rightarrow 0} z \cdot f_2(z) = 1$        $\left( \lim_{z \rightarrow 0} z^n \cdot f_2(z) = 0 \right)$   
 $f_3(z) \rightarrow \infty$  as  $z \rightarrow 0$  and  $f_3(z) \rightarrow L$  as  $z \rightarrow 0$

One can check  $f_1$  is analytic on the whole of the complex plane. So, we have actually in effect remove the singularity at 0 by redefining  $f_1$  at 0 itself to be 1, which is the limiting value of the definition of  $f_1$  and a neighborhood. So, if the limit we will see, that if the limit of  $f$  of a function  $f$  in a deleted neighborhood, as  $z$  goes to that a isolated singularity exists, then, then  $f$  will be analytic. Of course,  $f$  is analytic in the deleted neighborhood, then  $f$  is analytic in the whole of the disk and that singularity can be removed.

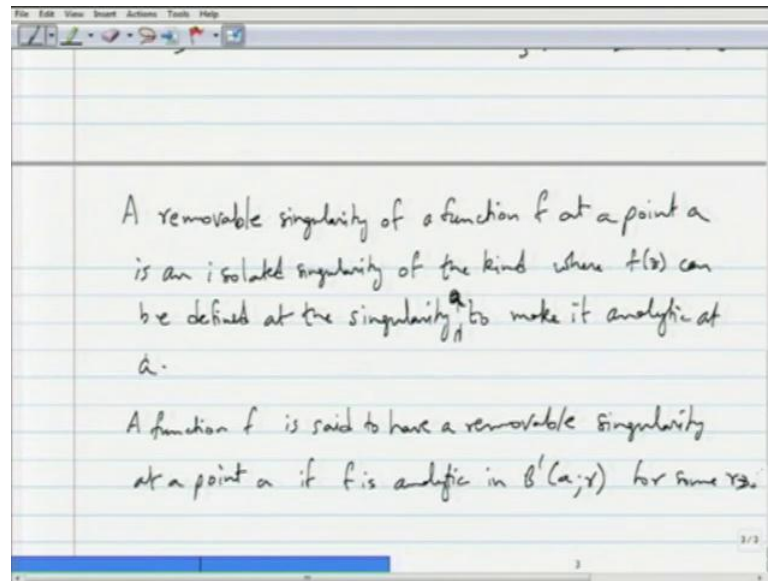

So, such a kind of singularity will be suggestively called as a removable singularity. So, another way of saying this is the function,  $f$  if it can be extended to an analytic function, even at the point which is the singularity. Then, then a such a kind of singularity is removed, such a kind of isolated singularity is removable, okay? We, we will define that in a moment, so but  $f_1$  here has such a kind of singularity.  $f_2$   $f_2$  of  $z$  has another kind of singularity,  $f_2$  of  $z$  notice that it tends to infinity as  $z$  tends to 0, whether you consider this definition or the that definition of  $f_2$  on  $\mathbb{C}$  minus 0, here also I should have select  $\mathbb{C}$  minus 0.

So, whichever definition we consider, we know that as  $z$  tends to 0, the modulus of the denominator becomes larger and larger. So,  $f^{-2}$  tends to infinity. So, this kind of singularity, so this kind of singularity has a definite pattern,  $f^{-2}$  of  $z$  in modulus tends to infinity or  $f^{-2}$  of  $z$  tends to infinity as we call it and also. Notice that,  $z$  times  $f^{-2}$  of  $z$  if you consider the first definition limit as  $z$  goes to a 0 of  $z$  times  $f^{-2}$  of  $z$  is 1 are if you consider the other definition in the parenthesis of  $f^{-2}$ . Then limit as  $z$  goes to 0 of  $z$  power  $n$  times  $f$  of  $z$   $f^{-2}$  of  $z$  is equal to 1. In either case the limit of the appropriate power of  $z$  minus 0, which is  $z$  times  $f^{-2}$  is a non zero quantity and that actually characterizes the the the kind of singularity of  $f^{-2}$  and 0.

So,  $f^{-1}$  is actually analytic of  $z$  is said to have a pole at the at the singularity 0. The singularity zero of  $f^{-2}$  is said to be a pole, okay? Then we will see something we will define something called the order of the pole that integer  $n$  here or one in this case we will we will call that as the order of the pole. We will define that more concretely and that is another kind of singularity. Finally, you notice has different kind of singularity  $f^{-3}$  of  $z$  does not tend to infinity as  $z$  tends to 0 and sorry as  $z$  tends to 0 and  $f^{-3}$  of  $z$  does not approach a limit.

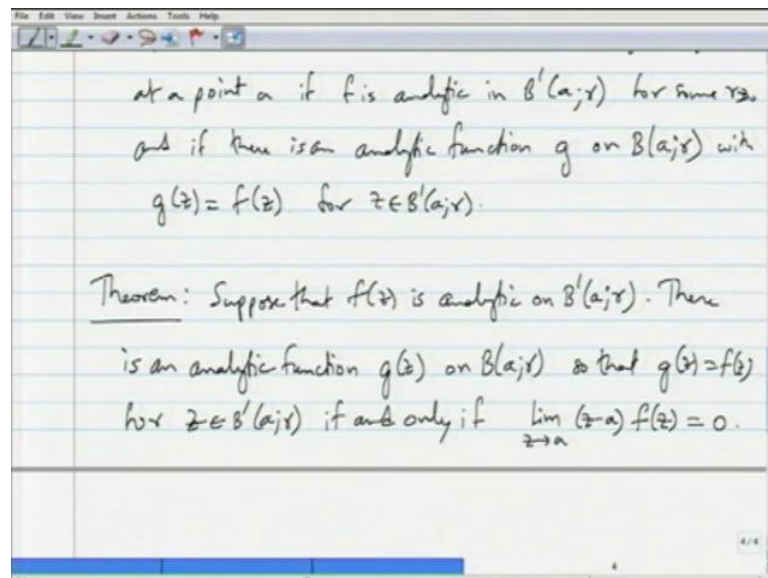

$f^{-3}$  that does not approach a finite, limit  $n$  as  $z$  approaches 0. There is no finite limit for a  $f^{-3}$  nor does it uniformly go off to infinity, so it, it is sort of jumping back and forth. Well, see a more concrete pattern to this jumping and then this kind of singularity is the third kind we will call this an essential singularity. We will see that the the Casorati Weierstrass theorem for these kind of singularities, okay? In a sense these are the only three kinds of behavior, we will also show that these are the only three kinds of behavior exhibited by a function, which is analytic in a deleted neighborhood of a point  $a$ , okay? So, let us proceed to classify the isolated singularities of a function. So, we will start with the removal similarity like I have said.

(Refer Slide Time: 11:42)

So, I will first define a removable singularity. If function  $f$  is said to have a removable singularity at a point  $a$ , if  $f$  is analytic in  $B'(a; r)$  for some  $r$  positive.

(Refer Slide Time: 12:23)

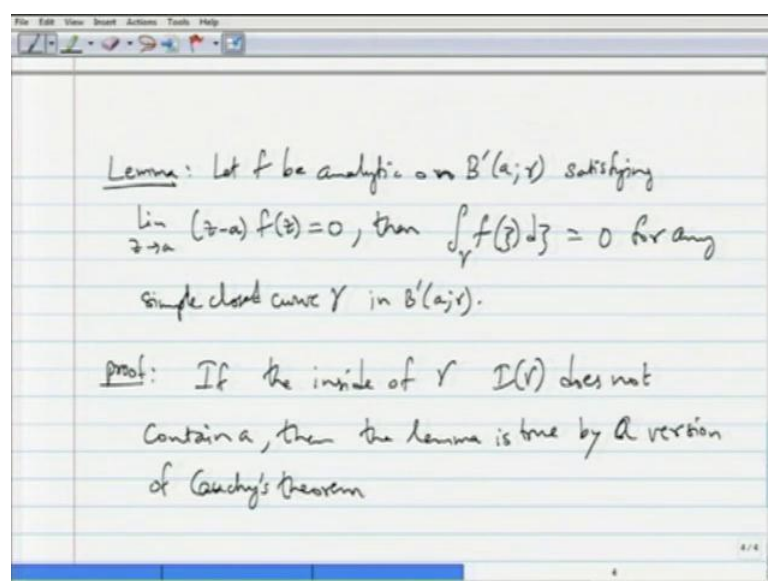

And if there is a function there is an analytic function  $g$  on the whole of  $B(a; r)$  which means it is already defined on at the point  $a$  itself with  $g(z) = f(z)$  for  $z \in B'(a; r)$ . So,  $g$  is an analytic function on  $B(a; r)$  which agrees with  $f(z)$  at all points in  $B'(a; r)$ . So, then  $f$  is said to have removable singularity, we will give a

criteria to identify removable singularity for a function  $f$ . So, here is the criteria, so here is the theorem, which states the criteria.

So, suppose that  $f$  of  $z$  is analytic on  $B$  prime of  $a$   $r$  where  $r$  is some positive quantity, there is an analytic function  $g$  of  $z$  on  $B$   $a$   $r$ . So, that  $g$  of  $z$  is equal to  $f$  of  $z$  for  $z$  belongs to  $B$  prime  $a$   $r$  if and only if limit as  $z$  goes to  $a$   $z$  minus  $a$  times  $f$  of  $z$  is equal to 0. So, if this condition is satisfied that the limit as  $z$  goes to  $a$  of  $z$  minus  $a$   $f$  of  $z$  is 0, then there is an analytic extension of  $f$  to the whole open disk  $B$   $a$   $r$ . If  $f$  is already analytic on  $B$  prime of  $a$   $r$ . So, and it goes the other way round. Of course, if  $g$  matches with  $f$  on  $B$  prime of  $a$   $r$  and  $g$  is analytic then limit  $z$  goes to  $a$   $z$  minus  $a$  times  $f$  of  $z$  will be 0 by continuity of  $g$ . So, so that direction is easy, but the other direction requires some work, okay?

So, in retrospect this is equivalent to saying that there is an analytic extension of  $f$  on to the disk  $B$   $a$   $r$ , if and only if the limit  $z$  goes to  $a$   $f$  of  $z$  is defined, if the limit exists. So, I am saying in retrospect in retrospect of what we are going to do, so if and if if we prove this theorem after we prove this theorem, we will see that that will imply that the statement that I have said. That limit  $z$  goes to  $f$  of  $z$  if it exists, then  $f$  can be redefined at  $a$  in order to make it analytic on the whole disk  $B$   $a$   $r$ . So, that is the theorem and in order to prove this theorem we will first see couple of lemmas, okay?

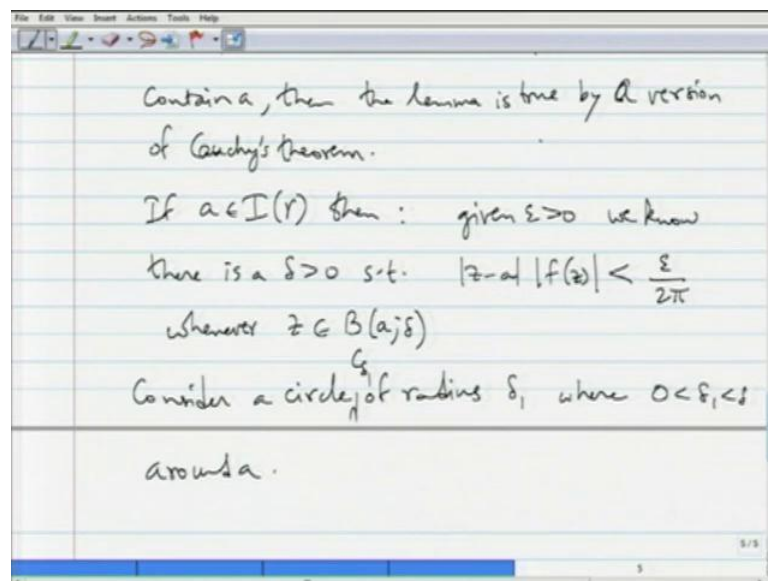

(Refer Slide Time: 16:27)

So, lemma before we prove this we will see this lemmas. Let  $f$  be analytic on  $B(a, r)$  or  $B$  prime  $a, r$  satisfying  $\lim_{z \rightarrow a} (z - a) f(z) = 0$ . Then  $\int_{\gamma} f(z) dz = 0$  for any simple closed curve  $\gamma$  in  $B$  prime of  $a, r$ . So,  $\gamma$  should lie in the deleted disk  $B(a, r) \setminus \{a\}$ . Then integration over  $\gamma$  of  $f$  is, so it is a modification to Cauchy's theorem.

So, what we are saying is that we can have a point  $a$ , at which we have a condition  $\lim_{z \rightarrow a} (z - a) f(z) = 0$ . With these kind of exceptional points the Cauchy's theorem still holds that the integration around any simple closed curve of  $f$  is 0, if  $f$  is analytic in  $B$  prime here. So, the proof is simple, so if the inside of  $\gamma$  does not contain  $a$ , then the lemma is true automatically by version of Cauchy's theorem, that we proved already because then your inside of  $\gamma$  is completely contained in the domain of analyticity of  $f$ . So, then this lemma is true. So, if  $a$  belongs to inside of  $\gamma$ , then we have we need some modification.

(Refer Slide Time: 18:55)

$a$  is inside of  $\gamma$ , then given  $\varepsilon$  greater than 0, we know there is a  $\delta$  positive because the limit the the the the said limit exists of  $z - a$  times  $f(z)$  and it is equal to 0, given  $\varepsilon$  greater than 0 there is a  $\delta$  greater than 0, such that modulus of  $z - a$  times modulus of  $f(z)$  is strictly less than  $\varepsilon$  by  $2\pi$ . We need this at just print factor. So, this is true when ever  $z$  belongs to a ball of radius  $\delta$  around  $a$ . So, then

now consider now consider a circle of radius delta 1 with where delta 1 is strictly less than delta delta 1 is positive strictly less than delta. So, I will call this circle C delta 1, consider a circle C delta 1 of radius delta 1 around a. So, the center of the circle is a and then integral over gamma f of zeta d zeta is equal to the integration around this circle. Now, C delta 1 of f of zeta d zeta.

(Refer Slide Time: 20:49)

$$\int_{\gamma} f(z) dz = \int_{C_{\delta_1}} f(z) dz \quad \text{by Cauchy's theorem,}$$

Then

$$\left| \int_{C_{\delta_1}} f(z) dz \right| \leq \int_{C_{\delta_1}} |f(z)| |dz| < \frac{1}{2\pi} \int \frac{\epsilon}{|z-a|} |dz|$$

This is because, now if you have this contour gamma oriented in the positive direction, if we take a circle of radius delta 1 around a then, we know by one version of Cauchy's theorem, that the integration over gamma of f of zeta d zeta is going to equal integration over the contour C delta 1 f of zeta d zeta. So, these are one and the same by version of Cauchy's theorem. So, this is by Cauchy's theorem for simple closed curves, so then then the modulus of of this integration f of zeta d zeta is less than are equal to the integration over C delta 1 of the modulus of f of zeta times modulus of d zeta is strictly less than well 1 by 2 pi times integration of epsilon.

Because modulus of f of zeta is less than epsilon by sorry, mod modulus of z minus a f of z is less than epsilon by 2 pi. I have modulus of f of z less than epsilon by modulus of z minus a in this case zeta minus a times modulus of d z d zeta, okay? So, notice this is true for every z in B a delta and this contour C delta one lies in completely inside this B a delta. So, for all points on the contour C delta 1 this this inequality holds this inequality. This estimate in terms of epsilon holds and so and so we can we can say that the modulus

of  $f$  of  $z$  is less than or equal to we can say less than are equal to  $1$  by  $2\pi\epsilon$  by modulus  $z$  minus  $a$  mod  $d$   $z$  minus  $a$ .

(Refer Slide Time: 23:24)

Then

$$\left| \int_{C_\epsilon} f(z) dz \right| \leq \int_{C_\epsilon} |f(z)| |dz| < \frac{1}{2\pi} \int_{C_\epsilon} \frac{\epsilon}{|z-a|} |dz|$$

$$= \frac{\epsilon}{2\pi} 2\pi = \epsilon$$

So  $\int_\gamma f(z) dz = 0$

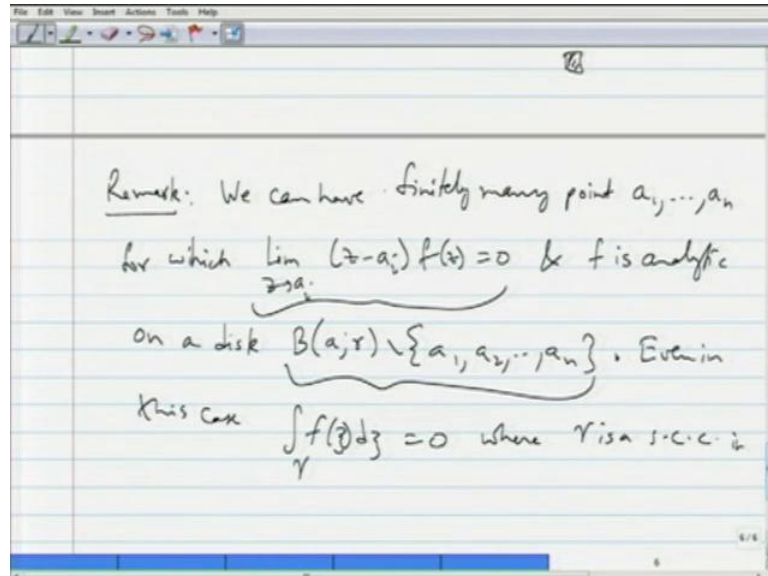

Then divide by  $2\pi$  this is on  $C_\epsilon$ , so this is equal to  $\epsilon$  by  $2\pi$  times  $2\pi$ . So, this integral  $1$  by mod  $z$  minus  $z$  minus  $a$  mod  $d$   $z$  minus  $a$  is  $2\pi$ . So, that cancels and this is equal to  $\epsilon$ . So, this is less than  $\epsilon$ , so this was a strict inequality sorry. So, this is a strict inequality here, so I get  $\epsilon$ . This is strictly less than  $\epsilon$ , so, this so in summary this integral is equal to this integral and this is arbitrarily small. So, so integration over  $\gamma$   $f$  of  $z$   $dz$  is equal to  $0$ .

So, notice that we have we have we have proved this by using a technique similar to Cauchy's theorem, but we are using Cauchy's theorem itself once again. What we are doing is, we are considering this contour  $\gamma$  which contains  $a$  in its interior. We are sort of contracting this this contour to a very small circle around  $a$  and then we are estimating the value of the function  $f$  on that circle around  $a$  itself. So, that is a technique very similar to  $1$  and Cauchy's theorem, but this condition, this condition that the limit  $z$  goes to  $a$   $f$  of  $z$  is equal to  $0$ , helps us give this estimate.

Then we can say that the integral of  $f$  around that circle is  $0$ , so the around the the integration over  $\gamma$  itself is of  $f$  of  $z$  is... So, that is the proof of this lemma there are only two cases that  $a$  is in the inside and  $a$  is not in the inside of  $\gamma$ . So, in either

case I have showed that the integral is 0, so that proves this lemma and we need one more lemma before we can prove the theorem.

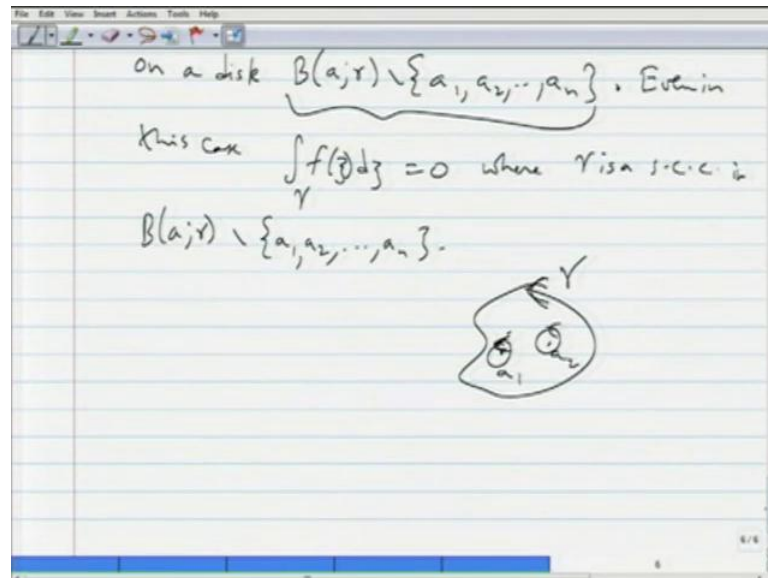

(Refer Slide Time: 25:43)

But first notice that, note so the here is the remark on this lemma we just proved we can have more than one points, we can have finitly many points  $a_1$  through  $a_n$  for which limit  $z$  goes to  $a_i$   $z$  minus  $a_i$  times  $f$  of  $z$  is equal to 0. And and of course, with assumption that  $f$  is analytic on well on a disk  $B(a_i, r)$  minus the points  $a_1$   $a_2$ , so on till  $a_n$ . Even in this general scenario, we can show that we can show that using the very same thing, we can, we can contract these disks  $a_1$  through  $a_n$ , which are finitely many points. We can contract these disks to smaller disks or contract this region to a very small disk around these points  $a_1$ , through  $a_n$ .

Then apply this lemma repeatedly to each of these disks to show that the above holds the same lemma holds with many points having such a such a condition limit  $z$  goes to  $a_i$   $z$  minus  $a_i$  times  $f$  of  $z$  is equal to 0, so even in this case, even in this case integration over  $\gamma$   $f$  of  $z$   $dz$  is equal to 0, where  $\gamma$  is a simple closed curve in  $B$ .

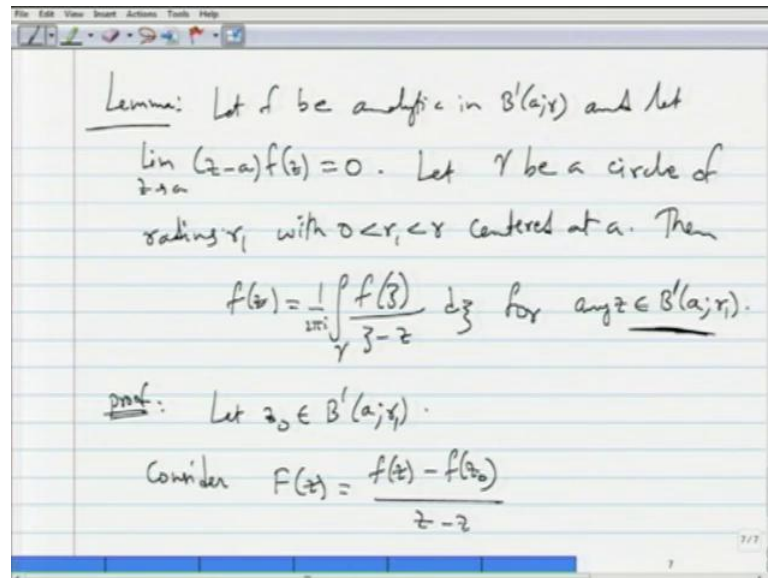

(Refer Slide Time: 01:33)

a  $r$  minus a  $1$  a  $2$  so on till a  $n$ . So, we have to slightly modify the technique of the proof of lemma to consider the case where more than one points  $a_1$  through  $a_n$  are inside  $\gamma$ . What you can do is actually, then take very small circles around these points. So, that the integration on  $\gamma$  equals the integration for the smaller circles which do not contain any other points. Then one of the  $a_i$ 's inside them and then by using Cauchy's theorem the integration on  $\gamma$ .

So, maybe a schematic will help, so here is  $\gamma$ . Suppose, it contains  $a_1$  and  $a_2$  you can consider two small circles around  $a_1$  and  $a_2$ . The integration over  $\gamma$  will equal the integration on these kind of circles and then we can use Cauchy's or the limit on  $a$ , the limit condition to show that the integration on the smaller circles of  $f$  is  $0$ . Hence, the integration on  $\gamma$  is  $0$ , okay? So, so that is a remark on the theorem and we need one more lemma.

(Refer Slide Time: 29:11)

Here, so let  $f$  be analytic what we are going to do is with the same condition limit  $z$  goes to  $a$   $(z-a)f(z)$  is equal to 0. We are going to say that the Cauchy's integral formula holds. So, in  $B'(a; r)$  and let limit  $z$  goes to  $a$   $(z-a)f(z)$  is equal to 0. So, if this condition holds, let  $\gamma$  be circle of radius  $r_1$  with  $0 < r_1 < r$  centered at  $a$ . Then  $f(z)$  is equal to the integration  $\frac{1}{2\pi i}$  times the integration of  $f(\zeta)$  by  $\zeta - z$   $d\zeta$  for any  $z$  belongs to  $B'(a; r_1)$ .

Note that, we use the Cauchy's integral formula to show that  $f(z)$  is equal to this particular thing this particular integral on the right hand side. That was a kind of representation formula for the value of  $f$  at points inside the circle. So that, we that we have emphasized, while showing I mean, while showing the version of Cauchy's integral formula. Here this lemma says that, that kind of representation formula for  $f(z)$  for  $z$  inside a circle of radius  $r_1$  like this is still valid, if  $z$  is not equal to  $a$   $(z-a)f(z)$  is equal to 0.

So, once again we will use this condition to actually show that all the previous results are the the Cauchy's integral formula still holds. So, let  $z_0$  belong to  $B'(a; r)$ , so I am picking an arbitrary point in  $B'(a; r)$ , sorry  $B'(a; r_1)$  and then I will show that this is representation formula holds. So consider, consider capital  $F(z)$  is equal to  $f(z) - f(z_0)$  by  $z - z_0$ .

(Refer Slide Time: 32:25)

Def: Let  $z_0 \in B'(a; r)$ .

Consider  $F(z) = \frac{f(z) - f(z_0)}{z - z_0}$ .  $F$  is analytic on  $B'(a; r) \setminus \{z_0\}$ .

$\lim_{z \rightarrow z_0} F(z)(z - z_0) = \lim_{z \rightarrow z_0} (f(z) - f(z_0)) = 0$ .

$\lim_{z \rightarrow a} F(z)(z - a) = \lim_{z \rightarrow a} \left( \frac{f(z)(z - a)}{z - z_0} - \frac{f(z_0)(z - a)}{z - z_0} \right) = 0 - 0 = 0$ .

Then notice that the limit  $z$  goes to  $z_0$  of capital  $F$  times  $z$  minus  $z_0$ , so firstly capital  $F$  is analytic on  $B'(a; r) \setminus \{z_0\}$ . So, we are in a situation like this a remark like in this remark. So, there are finitely many points and  $f$  is analytic in a disk minus some point removed, okay? So, we are in that kind of situation and  $F$  is analytic over there and limit  $z$  goes to  $z_0$  of  $f(z)$  minus  $f(z_0)$ . What is this? This is the limit as  $z$  goes to  $z_0$  of  $f(z)$  minus  $f(z_0)$ . Well  $z_0$  belongs to  $B'(a; r)$  where  $F$  is analytic.

So, it is continuous at least, so this limit is 0 also for the other ambiguous point a capital  $F$  of  $z$  times  $z$  minus  $a$ . This, what is this? This is the limit as  $z$  goes to  $a$  of  $f(z)$  times  $z$  minus  $a$  by  $z$  minus  $z_0$  minus  $f(z_0)$  times  $z$  minus  $a$  by  $z$  minus  $z_0$ . Each of these is 0, so the first one is 0 because of the given condition by the hypotheses and the second one is 0 because the limit as  $z$  goes to  $a$  of  $z$  minus  $a$  is 0. So, all in all this is 0 minus 0, this is 0. So, the limit exists and this is 0. So,  $B'(a; r) \setminus \{z_0\}$  in  $B'(a; r) \setminus \{z_0\}$  capital  $F$  is analytic. At the two points  $z_0$  and  $a$ , this kind of condition is satisfied.

(Refer Slide Time: 34:27)

$= 0 - 0 = 0.$

So by the above remark,

$$\int_{\gamma} F(z) dz = 0 \quad \text{for } \gamma \text{ as given}$$

$$\int_{\gamma} \frac{f(z) - f(z_0)}{z - z_0} dz = 0$$

So, by above lemma, so by the above remark, following the lemma, following the proof of the previous lemma, what we can say is that integration over gamma capital F of z d z is 0 for gamma has given. Since, since we are picking this point z naught inside the circle of radius r 1, there is a no danger of z naught itself lying on the circle of radius r 1. Also a is, a is not on the circle of radius r 1, centered at a. So, we have this integral 0. So, what this means is that the integration over gamma of f of z minus f of z naught by z minus z naught is equal to 0, d z is equal to 0. So, that is the definition of capital F of z.

(Refer Slide Time: 35:27)

$$\int_{\gamma} \frac{f(z)}{z - z_0} dz = f(z_0) \int_{\gamma} \frac{1}{z - z_0} dz$$

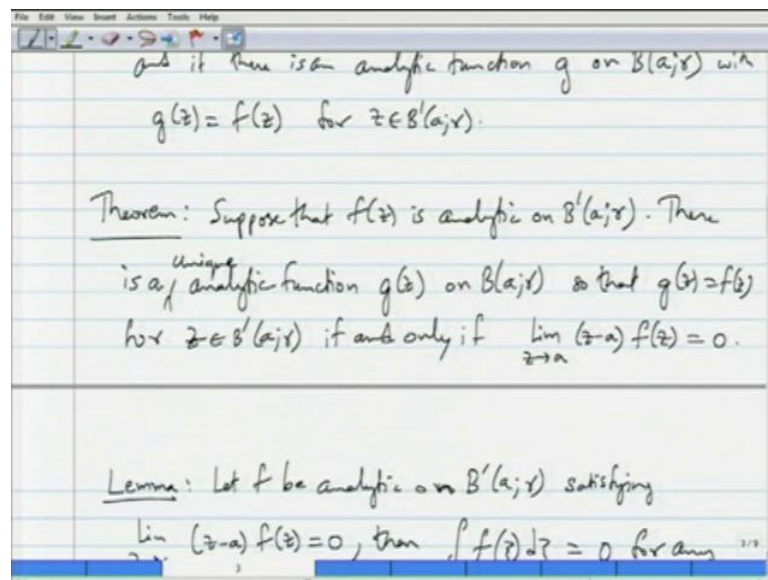

$$f(z_0) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(z)}{z - z_0} dz.$$

Since  $z_0 \in B'(a, r)$  was arbitrary, the lemma is proved.  $\square$

So, this tells that integration of  $f$  of  $z$  by  $z$  minus  $z$  naught  $d z$  is equal to over gamma equal to  $f$  of  $z$  naught times the integration over gamma of  $1$  by  $z$  minus  $z$  naught  $d z$ . We know that that integration is  $2\pi i$ , so this tells us that  $f$  of  $z$  naught is equal to  $1$  by  $2\pi i$  times integration over gamma of  $f$  of  $z$  by  $z$  minus  $z$  naught  $d z$ , which is what we want, okay? So, since  $z$  naught is arbitrary point inside  $B$  prime of a  $r$  1, so since  $z$  naught belongs to  $B$  prime a  $r$  1 was arbitrary, that lemma is proved. So, this representation formula holds for any such  $z$  naught, so that is the proof of this. Once again there is there can be a remark following this, that there can be more points than a itself, where this kind of condition can be satisfied.

Even then we can have the representation formula, where we avoid such points as  $a$ . So, now we are ready to prove the theorem. So, let us go back to the statement of the theorem, so this theorem says that if we have this really handy condition that  $z$  minus  $a$  times  $f$  of  $z$  is equal to  $0$ , in which case the two lemmas following this hold. Then there is an analytic extension to  $f$  of  $z$  at the point  $a$ , so one direction is pity easy. Also I, I will slightly add an important term to this theorem sorry, I will I will actually add there, there is a unique analytic function.

(Refer Slide Time: 37:52)

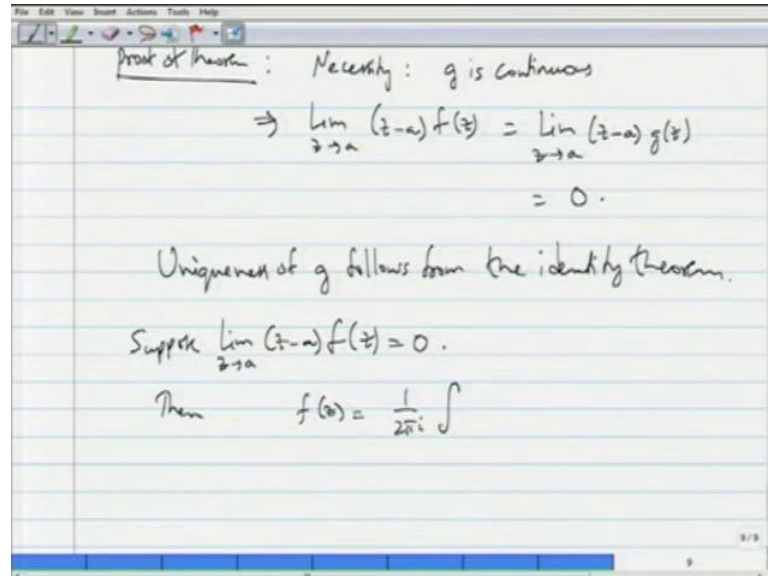

So, this function is also unique which gives more rigidity, okay? So, this should, this function such an extension is unique well the uniqueness is immediate because  $g$  and  $f$  agree on a set with a limit point. So, by that identity theorem the, the uniqueness

automatically follows, so that is a run much of a punch, but nevertheless uniqueness follows.

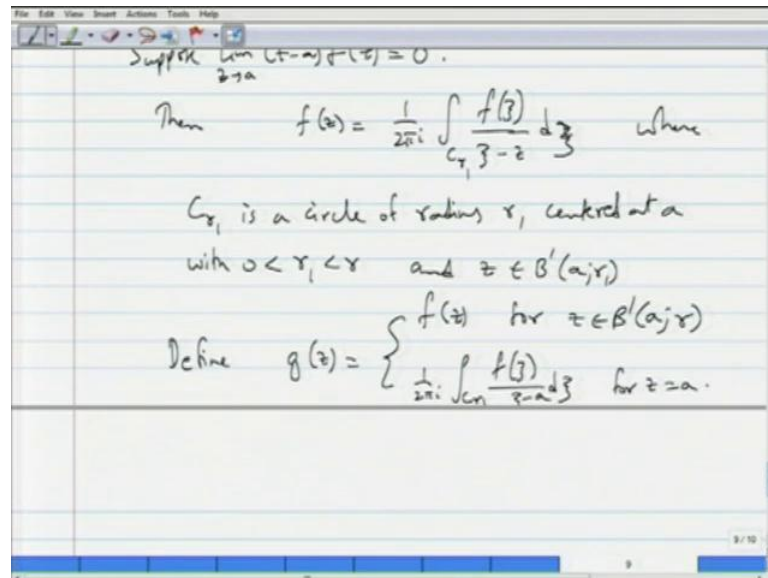

(Refer Slide Time: 38:23)

So, proof of theorem, so well the necessity condition is easy one direction of it is easy necessity says that, well requires that  $g$  is continuous. So, which implies that limit  $z$  goes to  $a$   $z$  minus  $a$   $f$  of  $z$  is equal to limit  $z$  goes to  $a$ , there is unique extension to  $f$  and that is  $g$ . So, we are assuming that, so then this is  $z$  minus  $a$  times  $g$  of  $z$   $f$  is equal to  $g$ . Then this is equal to limit  $z$  goes to  $a$ , well I mean this is  $0$  and that is  $0$ . So, this is equal to  $0$ , so the necessity is really easy uniqueness follows from of  $g$  follows from the identity theorem.

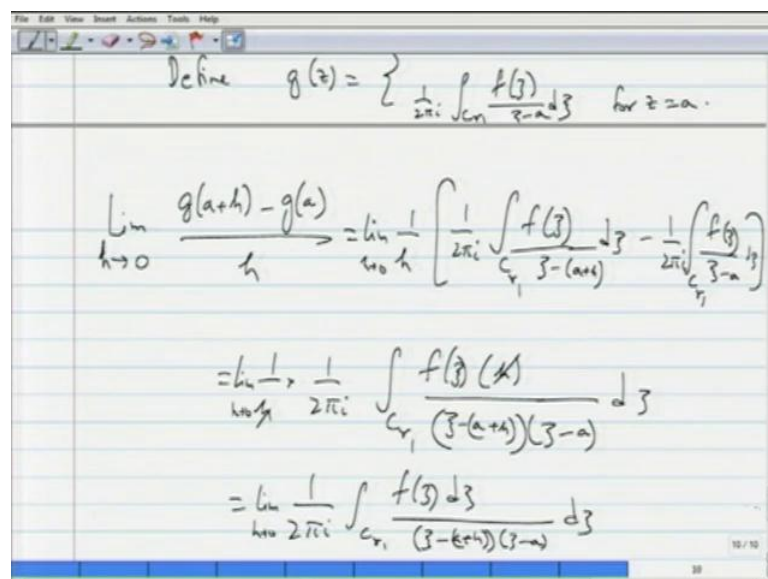

So, let me be more clear here what I mean is, if we know that there is a function  $g$  which extends  $f$  to the point  $a$  as well, then it has to be unique by the identity theorem. Because  $f$  and  $g$  have to agree that is the condition on  $g$ , so  $f$  and  $g$  have to agree on  $B$  prime  $a$   $r$ , which is a set with limit point. So, now I have to assume the condition that limit, limit  $z$  goes to  $a$   $z$  minus  $a$   $f$  of  $z$  exists and I have to show that  $f$  function exists. Now, suppose limit  $z$  goes to  $a$   $z$  minus  $a$   $f$  of  $z$  exists or is equal to  $0$  rather  $f$  of  $z$  is equal to  $1$  by  $2\pi i$  integration over  $C$   $r$   $1$  of  $f$  of  $\zeta$  by  $\zeta$  minus  $z$   $d z$ , where  $C$   $r$   $1$  is a circle of radius  $r$   $1$  centered at  $a$  with with  $0$  strictly less than  $r$   $1$  strictly less than  $r$  and  $z$  naught equal to  $a$  belongs to  $B$  prime  $a$   $r$   $B$  prime  $a$   $r$   $1$ .

(Refer Slide Time: 40:29)

So, by considering large enough circle we can actually include all the points in  $B$  prime  $a$   $r$ . So, this actually suggests the definition of the new function  $g$ . So,  $g$  of  $z$ , so define  $g$  of  $z$  is equal to well, we are force to define it to be  $f$  of  $z$  for  $z$  belongs to  $B$  prime  $a$   $r$ . Define this to be  $\frac{1}{2\pi i}$  integration over  $C_r$  if you place of  $f$  of  $\zeta$  by  $\zeta$  minus  $a$   $d\zeta$ . I apologize this should be  $d\zeta$   $\zeta$   $d\zeta$  for  $z$  equals  $a$ . So, will force it to be equal to this representation formula  $g$  to be equal to this representation formula, when, when  $z$  is equal to  $a$ .

(Refer Slide Time: 42:28)

We will show that  $g$  is analytic, so the limit as  $z$  or we can say limit as  $h$  goes to 0 of  $g$  of  $a + h$  minus  $g$  of  $a$  by  $h$ . There is no doubt that  $g$  is analytic in  $B$  prime  $a$   $r$  because  $f$  is... So, we will calculate this limit, this is equal to  $\frac{1}{2\pi i}$  times the integration over  $C_r$  of  $f$  of  $\zeta$  by  $\zeta$  minus  $a$  plus  $h$  d  $\zeta$  minus  $\frac{1}{2\pi i}$  times integration over  $C_r$  of  $f$  of  $\zeta$  pi  $\zeta$  minus  $a$  d  $\zeta$ . This is equal to  $\frac{1}{2\pi i}$  times to  $\frac{1}{2\pi i}$  times integration over  $C_r$  of  $f$  of  $\zeta$ .

I will combine these terms can clear the denominator I will get  $\zeta$  minus  $a$  minus  $\zeta$  minus  $a$  plus  $h$ . So, that will give me an  $h$  in the numerator divide by  $\zeta$  minus  $a$  plus  $h$  times  $\zeta$  minus  $a$ , so this  $h$  cancel and I have this is equal to  $\frac{1}{2\pi i}$ . So, I have a limit hanging in there limit  $h$  goes to 0 limit goes to 0 etcetera. This is limit as  $h$  goes to 0 of  $\frac{1}{2\pi i}$  integral over  $C_r$  of  $f$  of  $\zeta$  d  $\zeta$  by  $\zeta$  minus  $a$  plus  $h$  times  $\zeta$  minus  $a$  d  $\zeta$ .

(Refer Slide Time: 44:10)

$$\begin{aligned}
 &= \lim_{h \rightarrow 0} \frac{1}{2\pi i} \int_{C_r} \frac{f(z) dz}{(z-a+h)(z-a)} \\
 &= \lim_{h \rightarrow 0} \frac{1}{2\pi i} \int_{C_r} \frac{f(z) dz}{(z-a+h)(z-a)} \\
 &= \frac{1}{2\pi i} \int_{C_r} \frac{f(z) dz}{(z-a)^2}
 \end{aligned}$$

So  $g$  is analytic at  $a$  &  $g$  is a extension of  $f$  as desired.

So, now I can take the limit into the integral, and then this is equal to  $\frac{1}{2\pi i}$  integral over  $C_r$  of  $f$  of  $\zeta$  d  $\zeta$  divide by  $\zeta$  minus  $a$  square d  $\zeta$ . So, this limit exists, limit  $h$  goes to 0  $g$  of  $a + h$  minus  $g$  of  $a$  by  $h$  it exists and it equals  $\frac{1}{2\pi i}$   $C_r$  1 integration over  $C_r$  of  $f$  of  $\zeta$  d  $\zeta$  by  $\zeta$  minus  $a$  square d  $\zeta$ , whatever that value is. So,  $g$  is analytic at  $a$ , and  $g$  is a extension of  $f$  as desired. So, that completes the proof of this theorem and will see other kinds of singularities, next time.
