Problem Solving Session

Hello viewers, in this session, we will solve some problems based on the theory we have seen. So, let me begin with the calculation of a residue, so the viewer once again is asked to pause after each the problem, and try to solve the problem by himself or herself. Then I am anyway going to present the solutions to those problems.

(Refer Slide Time: 00:52)

So, let me start with a question on residues, so calculation of residues. So, find a the residue of the function f of z equals z minus $\sinh z$ divided by z squared $\sinh z$ at the point z equals πi here by $\sinh z$, I mean the hyperbolic sine z . Now, try to solve this problem and here is the solution to this question, okay? So, first notice that this function f has a 0 at z equals πi I mean the denominator has a 0 at z equals πi . So, $\sinh z$ at πi is \sinh of πi , which is \sinh of $i \pi$ is $\sin \pi$. We know this formula from our earlier considerations, \sinh of $i z$ is $i \sin z$, so this gives us a 0.

So, the denominator has a 0 at πi . Also notice that, the 0 of \sinh of the sine function at π is a simple 0. So, what that means is that the $\sinh z$ has a simple 0 another z equals

πi . Now, using that fact we know that if we write f of z is equal to z minus $\sin h z$ by z squared and times 1 by $\sin h z$. So, $\sin h z$ has a simple 0 at z equals πi , so f has a simple pole at z equals πi . So, in order to find the residue, we just need to find the coefficient of 1 by z minus a , in the Laurent series expansion for f of z . So, how do that? We will resort to the power series expansion first of $\sin h z$.

So, notice that $\sin h z$ the power series of this around z equals πi is going to be $\sin h$ at πi itself is 0 plus the derivative of $\sin h z$, the first derivative of this at the point z equals πi divided by 1 factorial times z minus πi , plus $\sin h z$ the second derivative of $\sin h z$ by 2 factorial times z minus πi squared, plus the third derivative of $\sin h z$ at the point z equals πi . So, all this at z equals πi at z equals πi divided by 3 factorial times z minus πi cube. So, for lack of space I will write below z minus πi cube, plus so on. There are higher order terms.

(Refer Slide Time: 04:39)

$$\begin{aligned} \sinh(z) &= 0 + \frac{(\sinh z)'}{1!} (z - \pi i) + \frac{(\sinh z)''}{2!} (z - \pi i)^2 + \frac{(\sinh z)'''}{3!} (z - \pi i)^3 + \dots \\ &= \frac{(-1)}{1!} (z - \pi i) + \frac{0}{2!} (z - \pi i)^2 + \frac{(-1)}{3!} (z - \pi i)^3 + \dots \\ &= (z - \pi i) \left(-1 + \frac{(-1)}{3!} (z - \pi i)^2 + \dots \right) \\ &= (z - \pi i) (-1 + g(z)) \quad \begin{matrix} g(\pi i) = 0 \\ g \text{ analytic} \end{matrix} \end{aligned}$$

So, notice that the first derivative of $\sin h z$, itself is a $\cos h z$. So, that will give us $\cos h$ z at z equals πi which is $\cos \pi$, so that gives us -1 by 1 factorial times z minus πi plus, well the second derivative of $\sin h z$ at at the point z equals πi is a $\sin h z$ itself at z equals πi , which gives us 0 by 2 factorial times z minus πi squared, plus the third derivative is once again $\cos h z$ at z equals πi gives us -1 . Once again divided by 3 factorial times z minus πi cube plus so on.

So, this is this can be written as $z - \pi i$ times -1 plus well -1 by 3 factorial times $z - \pi i$ cube plus, so on and all these so on terms will have a $z - \pi i$ power something positive integer. So, this can be I will write this as $z - \pi i$ times -1 plus a function ϕ of z , which is 0 at πi ϕ of πi what is important is ϕ of πi is 0 and ϕ is analytic function, ϕ analytic. So, this is definitely valid this Taylor's series expansion of $\sinh z$ is definitely valid in some in some neighbourhood of πi , such that r is strictly positive.

(Refer Slide Time: 06:54)

The image shows a digital whiteboard with the following handwritten content:

$$= \frac{(-1)}{1!} (z - \pi i) + \frac{0}{2!} (z - \pi i)^2 + \frac{(-1)}{3!} (z - \pi i)^3 + \dots$$

$$= (z - \pi i) \left(-1 + \frac{(-1)}{3!} (z - \pi i)^3 + \dots \right)$$

$$\sinh(z) = (z - \pi i) (-1 + \phi(z)) \quad \begin{matrix} \phi(\pi i) = 0 \\ \phi \text{ analytic} \end{matrix}$$

in $B(\pi i; r) \quad r > 0$

$$f(z) = \frac{z - \sinh(z)}{(z - \pi i) (-1 + \phi(z)) z^2} = \frac{1}{z - \pi i} \left(\frac{z - \sinh(z)}{(-1 + \phi(z)) z^2} \right) \text{ in } B(\pi i; r)$$

$$\text{Res}(f; \pi i) =$$

So, all this expression is definitely valid in some some disk around πi , okay? So, now we will use this expression in f of z f of z is equal to $z - \sinh z$ divided by $z - \pi i$ times -1 plus ϕ of z times z squared. So, notice that this part is analytic at z equals πi for f of z . So, since we know that the pole of f at πi is simple we know that the residue of f of z at z equals πi , we just simple has to be, has to be 1 by...

Well, before I write that this is now equal to 1 by $z - \pi i$ times all this function $z - \sinh z$ divided by $-1 + \phi$ of z times z squared at least in a neighbourhood of πi in a $B(\pi i; r)$. So, locally around πi at least this expression is valid. So the residue of this is going to be well here is a analytic function in $B(\pi i; r)$. So, the value of this at the point πi itself will give us the residue.

(Refer Slide Time: 09:02)

$$= (z - \pi i) \left(-1 + \frac{(-1)}{z!} ((z - \pi i)^2 + \dots) \right)$$

$$\sinh(z) = (z - \pi i) (-1 + g(z)) \quad (g(\pi i) = 0 \leftarrow \text{by def.})$$

$$\text{in } B(\pi i; r) \quad r > 0$$

$$f(z) = \frac{z - \sinh(z)}{(z - \pi i)(-1 + g(z))z^2} = \frac{1}{(z - \pi i)} \left(\frac{z - \sinh(z)}{(-1 + g(z))z^2} \right) \text{ in } B(\pi i; r)$$

$$\text{Res}(f; \pi i) = \lim_{z \rightarrow \pi i} (z - \pi i)f(z) = \frac{\pi i - 0}{(-1 + 0)(\pi i)^2} = \frac{\pi i}{\pi^2} = \frac{i}{\pi}$$

So, or in other words this is the limit as z goes to πi of z minus πi times f of z . So, this factor of z minus πi cancels with this and this gives us πi minus $\sinh \pi i$, which is 0 divided by $-1 + 0$ remember ϕ at πi is 0 , like I mentioned here. Then z squared is πi whole squared which gives us πi by -1 minus πi squared, so it is πi squared so this is i by π . So, that is the residue of f of z at the point z equals πi . So, this is an example in calculation of residue. So, let us see another example of this sort.

(Refer Slide Time: 10:02)

Ex: Suppose that g is an analytic function in $B(z_0; r)$ & that $g(z_0) = 0$ & $g'(z_0) \neq 0$. Assume $g(z) \neq 0$ in $B'(z_0; r)$.

Define $f(z) := \frac{1}{(g(z))^2} \quad z \in B'(z_0; r)$

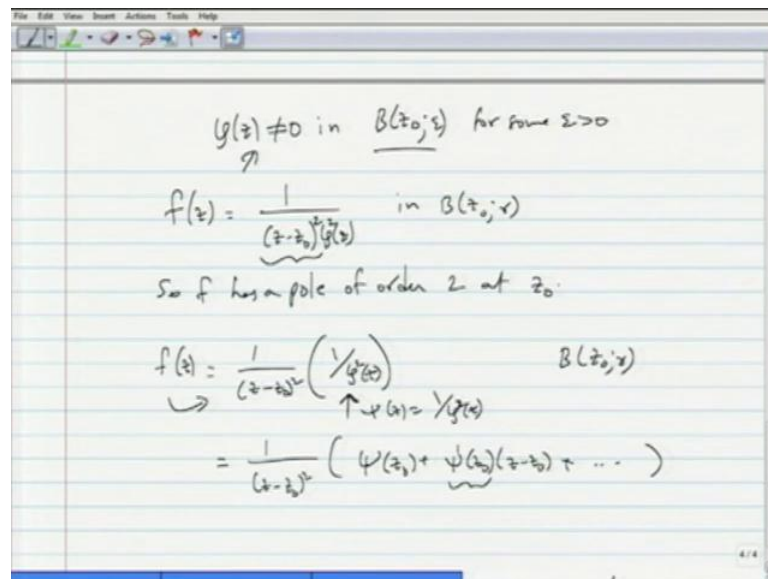

Show that f has a pole of order 2 at z_0 . Calculate $\text{Res}(f; z_0)$.

Solution: $g(z) = (z - z_0) \left(g'(z_0) + \frac{g''(z_0)}{2!} (z - z_0)^2 + \dots \right) \text{ in } B(z_0; r)$

So, um example two, suppose that q is an analytic function in $B(z_0, r)$. So, and that q of z_0 is 0 and q' of z_0 is non zero, define f of z is equal to 1 by q of z squared, okay? So, also you probably need to assume that assume q of z is not equal to a 0 in B prime z_0 r . So, z_0 is the only 0 of q in B z_0 r so define f of z as 1 by q of z squared for z belongs to B prime z_0 r . So, show that f has a pole of order 2 at z_0 calculate the residue of f at the point z_0 . So, the viewer can try to answer this problem and here is the solution to this problem.

So, firstly note that q is analytic at z_0 and has a 0 at z_0 , so q of z is equal to z minus z_0 times using Taylor's theorem. Let us say this is Q' of z_0 plus q'' of z_0 divided by 2 factorial times z minus z_0 plus q''' higher derivatives of q . So, allow me to call this function as ψ of z for convenience and this expression is valid definitely in B z_0 r , which is the domain of analyticity of q . It is given that Q' of z_0 is non zero, so q has a simple zero at z_0 .

(Refer Slide Time: 13:27)

Now, f of z , now I have to remark here that T of z is non zero in B z_0 ϵ for some ϵ positive k so ψ of z_0 itself is non zero because Q' of z_0 is non zero. The, then by continuity of ψ you can say that ψ of z is non zero in B z_0 ϵ , okay? So Q has a simple 0 at z_0 . So, f of z is equal to 1 by z minus z_0 times ψ of z in B z_0 r and I apologise a squared ψ squared

because f is $1/q^2$ of z whole squared. So, f is that and ϕ of z is non zero in $B(z_0, \epsilon)$. So, f has a simple or a pole of order 2 at...

So, just by looking at this expression we can conclude that f has a pole of order 2 at z_0 . So, if we break the expression for f of z as $1/z^2$ times the function $1/\phi^2$ of z , then we can write the power series expansion of this expression in $B(z_0, r)$ by ϕ of z is non zero q is non zero in all of $B(z_0, r)$. So, ϕ is not going to be 0, there in $B(z_0, r)$. Then $1/\phi^2$ of z can be expanded as a power series or by Taylor series. So, the first derivative of $1/\phi^2$ of z is going to give us coefficient of $1/z$ for the expansion for the Laurent series expansion of f of z and that will tell us the residue of f . Remember the residue is just a coefficient of $1/z$ in the Laurent series expansion for f of z .

So, all we need to do is find the first derivative here the reason, I am saying that is the first derivative is that, if I call this function some $\psi = 1/\phi^2$ of z is ψ . Then $1/z^2$ times ψ of z plus. Similarly, prime of z times $1/z^2$ etcetera is the power series expansion of ψ , ψ is this function $1/\phi^2$ of z . So this coefficient will give me the the coefficient of $1/z$ for f of z .

(Refer Slide Time: 17:05)

$$\begin{aligned} \psi'(z) &= \left(\frac{1}{q^2(z)} \right)' = -2q^{-3}(z) q'(z) \Big|_{z=z_0} \\ &= -2 \frac{(q'(z_0))^2 q''(z_0)}{2} \\ &= -\frac{q''(z_0)}{(q'(z_0))^3} \end{aligned}$$

$$\text{Res}(f; z_0) = \frac{-q''(z_0)}{(q'(z_0))^3}$$

So, let us find that the first derivative of ψ ψ prime of z is going to be the derivative of 1 by ψ squared of z at the point z naught at the point z equals z naught. So, this is going to be minus 2 ψ power minus 3 of z times ψ prime of z . So, this is minus 2 ψ power minus 3 of z times ψ prime. So, you just have to look at what ψ of z is so ψ of z itself has this kind of expansion around z naught. So, ψ of z ψ prime of z is going to be your q double prime of z naught, so ψ of ψ prime of z is q double prime of z naught divided by 2 factorial ψ power minus 3 of z 1 by ψ cube of z at z naught is q prime of z naught power minus 3 .

So, this is I forgot the 2 factorial, so this is divided by two so this gives minus q double prime of z naught divided by q prime of z naught cube. So, the residue of f at the point z naught is going to be minus q double prime of z naught divided by q prime of z naught cube, so it is the residue and f has a pole of order 2 at z naught, that is the solution to this problem.

(Refer Slide Time: 19:16)

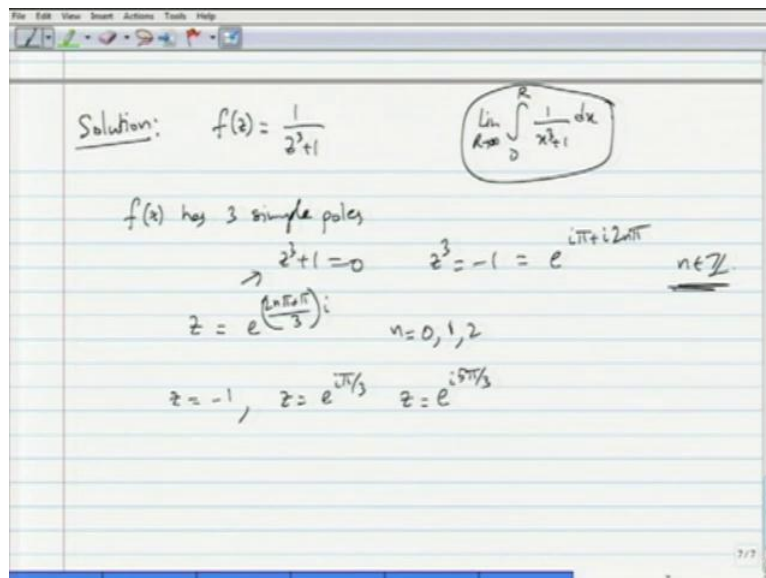

Now, we will move on to the next problem, this question is a contour integral of certain sort. So, use a residue and the following contour, so the contour is as follows. So, you start at the origin go until some point R on the real line and then you go along a circular contour. So, that is the portion of a circle. Then this is the ray θ equals 2π by 3 , so this is the angle 2π by 3 , so you start from origin, go in this direction, go along the circle and come back to the origin along the ray θ equals 2π by 3 . So, this point

itself is $\operatorname{Re} \int_0^R \frac{1}{x^3+1} dx$. That is this point, so let us call this this whole contour a gamma, okay?

Use a residue and the following contour to show that $\int_0^\infty \frac{1}{x^3+1} dx = \frac{2\pi}{3\sqrt{3}}$. So, let me pause here to mention that we can calculate indefinite integrals of these sorts. So, real indefinite integrals by using Complex analysis and Cauchy's residue theorem. So, this is one example from the set of examples, which can be solved thus, so the viewer is advised to look into text books which have been recommended to solve more problems of this sorts.

And some of the text books actually give a whole tool kit in order to a technical tool kit in order to solve, a integrals of this sort of find indefinite integrals of these sort using Cauchy's residue theorem, okay? So, we are not going to present the whole tool kit here, but what we are going do is study couple of examples in that direction. So, here is one example in that direction, so given this contour show that this indefinite integral has that value.

(Refer Slide Time: 22:40)

So, I will present the solution to this problem here, so looking motivated by this function here $\frac{1}{x^3+1}$ which is the integrand, so I am sort of considering motivated by that, I am considering the function $\frac{1}{z^3+1}$. So, this function notice that on the real line from 0 to ∞ $\int_0^R \frac{1}{x^3+1} dx$ is a real number on the real line on 0 to ∞ it gives me $\int_0^\infty \frac{1}{x^3+1} dx$ when I integrate f of z , okay? So, and if I take the limit as R goes

to infinity there is hope that I will be able to get what I want. I will be able to evaluate this indefinite integral hopefully.

So, motivated by that I am considering this function $f(z) = \frac{1}{z^3 + 1}$. Notice that $f(z)$ has 3 simple poles, $z^3 + 1$ is a polynomial or $z^3 + 1$ is a polynomial. So, $z^3 + 1$ has 3 simple poles. Since, we know the solutions to $z^3 + 1 = 0$. We have seen examples of these sorts, we want to solve $z^3 = -1$. So, if we write -1 as $e^{i\pi}$ or $e^{i\pi + 2n\pi i}$. So, $i\pi + 2n\pi i$ rather n belongs to z integers. Then we know that, z can be can take the values $e^{i\pi + 2n\pi i}$ divided by 3 times i and all the values of i means m belongs to z are going to be (ω^k) . So, we will just use $0, 1$ and 2 from 3 onwards, we are going to get back solution. We already got, so we have seen this procedure earlier. $z = -1$ is one such root and $z = e^{i\pi/3}$ is one root of this of this equation.

The third one is going to be $z = e^{i2\pi/3}$, so $n = 0$ corresponds to $z = e^{i\pi/3}$, $z = e^{i2\pi/3}$ is going to give us, $2\pi/3 + \pi/3 = \pi$, which is $z = -1$. $n = 2$ gives us, $2\pi + \pi/3 = 7\pi/3$, okay? So these are the 3 roots of $z^3 + 1 = 0$ and hence these are the three simple poles of $f(z)$. These three points and notice that given this contour given this closed contour given simple closed contour, there is only one among these three, which is in the inside of this contour namely $e^{i\pi/3}$, which occurs on the line $\theta = \pi/3$ on the half ray $\theta = \pi/3$. The others are on the negative real axis and in the fourth quadrant.

(Refer Slide Time: 26:20)

Q: Use a residue & the following contour γ :

to show that
$$\int_0^{\infty} \frac{dx}{x^2+1} = \frac{2\pi}{3\sqrt{3}}$$

(Refer Slide Time: 26:55)

By Cauchy's residue theorem

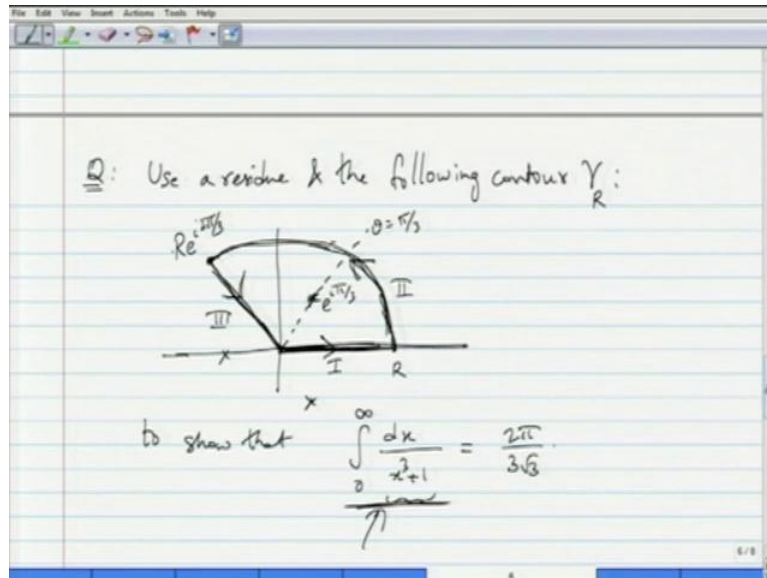

$$\int_{\gamma_R} f(z) dz = 2\pi i \operatorname{Res}(f, e^{i\pi/3}) \quad \text{--- (1)}$$

$$\int_{\gamma_R} f(z) dz$$

One this is a conjugate, this is a conjugate of this, so those are the three poles of f of z . So, the contour integration form by Cauchy's residue theorem. We know that the contour integration of f over γ . So, let me suggestively call this contour γ_R because I have a variable R here capital r here. So, the integration over γ_R of f of z dz has to be $2\pi i$ times the residue of f at the point $e^{i\pi/3}$, but that is only a half of the story. Of course, I want to know, how I can get this integral or at least integral 0 to 1 by $x^2 + 1$ dx out of this equation?

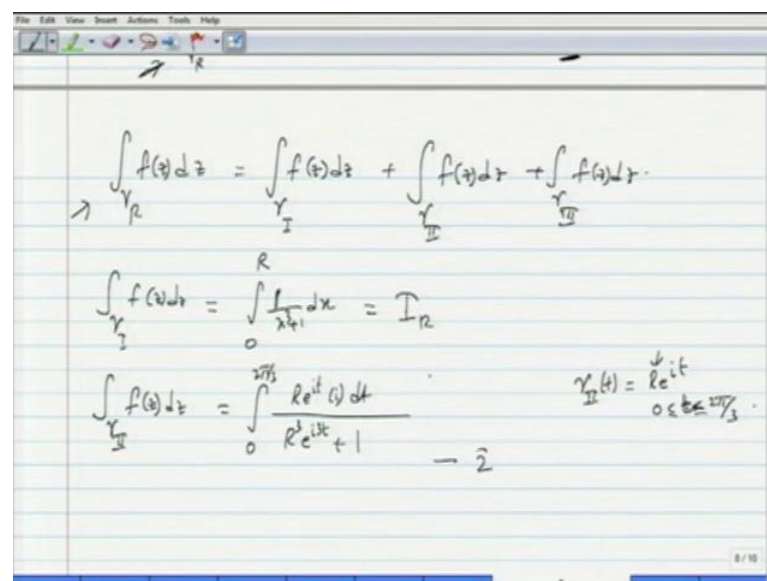

One, let me call that 1, now for in order to see, how I get that expression. Now, let me break the contour into its natural parts and let me consider the integral from 0 to r on the real line, okay? So let us concentrate on $\int_{\gamma_R} f(z) dz$ the integration of f on γ_R . So, it constitutes of three parts.

(Refer Slide Time: 28:20)

One is this real line part two is this semicircular part and three is this half ray part. So, let us consider each one of them separately.

(Refer Slide Time: 28:34)

So, let me call that integration over gamma 1 $\int_{\Gamma_1} f(z) dz$ plus integration over gamma 2 $\int_{\Gamma_2} f(z) dz$ plus integration over gamma 3, $\int_{\Gamma_3} f(z) dz$ with their provided orientations. So, when we consider integration over gamma 1 $\int_{\Gamma_1} f(z) dz$. So, this is equal to well integration from 0 to r of $f(1/x^3 + 1) dx$ like we want because $f(z)$ is $1/z^3 + 1$ and z is real on gamma 1. So, that is good and then integration over gamma 2 of $f(z) dz$ is going to be on gamma 2.

Let us parameterize gamma 2 as gamma 2 of t is equal to re^{it} , where t ranges from 0 to $2\pi/3$. So, this is a portion of a circle, so that is how we can parameterize it is t a circle of radius r ? So, this is integration from 0 to $2\pi/3$ of dz is re^{it} times $i dt$. Then in the denominator we have $z^3 + 1$ on gamma 2 of t is $r^3 e^{i3t} + 1$. So, we will preserve this expression as a equation two and on gamma 3 $\int_{\Gamma_3} f(z) dz$ by using the parameterization gamma of t is equal to gamma.

(Refer Slide Time: 30:43)

$$\int_{\Gamma_2} f(z) dz = \int_0^R \frac{1 - e^{2\pi i/3 y}}{e^{2\pi i/3 y} + 1} dy$$

$$= - \int_0^R \frac{\left(-\frac{1}{2} + i\frac{\sqrt{3}}{2}\right) dt}{t^3 + 1}$$

$$= \left(\frac{1}{2} - i\frac{\sqrt{3}}{2}\right) \int_0^R \frac{dt}{t^3 + 1} = \left(\frac{1}{2} - i\frac{\sqrt{3}}{2}\right) I_R$$

$\gamma(t) = e^{2\pi i/3 t}$
 $R \gg t \geq 0$

Three of t is equal to $e^{2\pi i/3 t}$ where t goes from R to 0. So, notice that the orientation on this is from this point towards the origin. So, I have to use t goes from R to 0. So, this is equal to integration from R to 0 of gamma prime gamma 3 prime is going to give me 1 times $e^{2\pi i/3 t}$ divided by gamma, sorry $z^3 + 1$ is going to be $e^{2\pi i/3 t} + 1$.

So, this is by changing the limits of integration to 0 to R , I get a minus sign. $2\pi i/3$ is $\cos 2\pi/3 + i \sin 2\pi/3$ divided by $e^{2\pi i/3 t} + 1$.

3 cube gives me 1. So, this is t cube plus 1. So, by absorbing the minus sign into the complex number I get, half minus i root 3 by 2 times integration from 0 to R d t by t cube plus 1, but notice that this of looks like the integral that we need, so this is this complex number half minus i root 3 by 2 times the integral that we need with the variable R. So, let me call that i r.

(Refer Slide Time: 32:57)

$$2\pi i \operatorname{Res}(f(z); e^{i\pi/3}) = I_R + \left(\frac{1}{2} - \frac{i\sqrt{3}}{2}\right)I_R + \int_0^{2\pi/3} \frac{iRe^{it} dt}{R^3 e^{3it} + 1}$$

$$\left| \int_0^{2\pi/3} \frac{iRe^{it} dt}{R^3 e^{3it} + 1} \right| \leq R \int_0^{2\pi/3} \frac{|dt|}{|R^3 e^{3it} + 1|}$$

$$|R^3 e^{3it} + 1| \geq R^3 - 1$$

So, the residue $2\pi i$ times the residue of f of z at the point $e^{i\pi/3}$ from equation one. We notice that from equation 1, we notice that $2\pi i$ times residue of that is equal to integration over γ_R of f of z dz . So, this is in turn equal to $i r$ plus this complex number half minus i root 3 by 2 $i r$ which are the integrations on γ_1 and γ_3 respectively plus the integration on γ_2 is this expression here, which we preserved integration from 0 to $2\pi/3$ of $r e^{i t}$ $i r e^{i t} dt$ by $R^3 e^{3it} + 1$.

So, limit as R goes to infinity is what we are interested in because $i r$ as R goes to infinity gives us the definite integral or the improper integral that we want. So, if we can calculate we can calculate the residue here, so if we can calculate this integral or we if we can estimate this integral and say something, then we will be able to conclude something about $i r$ as R goes to infinity. So, with that as motivation let us examine modulus what this integral comes to $i r e^{i t} dt$ by $R^3 e^{3it} + 1$ in modulus this is less than or equal to well in the numerator the modulus of $r i e^{i t}$ is going to be,

simply R is a positive real number. Then integration from 0 to 2π by 3 of modulus of d t divided by the modulus of $R^3 e^{3it} + 1$.

(Refer Slide Time: 36:01)

The slide shows the following derivation:

$$\left| \int_0^{2\pi/3} \frac{i R e^{it} dt}{R^3 e^{3it} + 1} \right| \leq R \int_0^{2\pi/3} \frac{|dt|}{|R^3 e^{3it} + 1|} \leq \frac{R}{R^3 - 1} \frac{2\pi}{3} (R)$$

$$= \frac{2\pi}{3} \frac{R^2}{R^3 - 1} \rightarrow 0 \quad \text{as } R \rightarrow \infty$$

Below the equations, there are two diagrams illustrating the modulus of the denominator:

- The first diagram shows a circle of radius R^3 centered at the origin in the complex plane. A point on this circle is labeled $R^3 e^{3it}$.
- The second diagram shows a circle of radius R^3 centered at 1 on the real axis. This represents the shifted circle $R^3 e^{3it} + 1$.

So, notice that the modulus of $R^3 e^{3it}$ is a point on the unit circle and R^3 tells us that it is this complex number is a point on the circle of radius R^3 . And then plus 1 tells us that this is in modulus, so this in modulus is at least at least $R^3 - 1$, so that is because if you take the circle of radius R^3 around the origin and shift it to the right by adding 1. Then this circle goes to some circle like that, so the origin is now off centre its off centre and this distance is at least $R^3 - 1$. So, any point on this circle now on this shifted circle, so transformation is by plus 1 on the shifted circle at least has modulus $R^3 - 1$, okay?

So, it is the idea, so 1 by the modulus of $R^3 e^{3it} + 1$ is going to be less than or equal to $1 / (R^3 - 1)$. So, this is less than or equal to this integral is less than or equal to $R / (R^3 - 1)$ times the length of this the this curve 0 to $2\pi/3$ of modulus of d t , which is a portion of a circle which is pictured in the contour. So, this is $2\pi/3$ times R . So, that is the length of that curve, now you see that this is equal to $R^2 \cdot 2\pi/3 / (R^3 - 1)$. So, which tends to 0 as R tends to infinity. Remember we are interested in the integral as R tends to infinity.

(Refer Slide Time: 37:55)

$$= - \int_0^R \frac{(\frac{1}{2} + i\frac{\sqrt{3}}{2}) dt}{t^3 + 1}$$

$$= (\frac{1}{2} - i\frac{\sqrt{3}}{2}) \int_0^R \frac{dt}{t^3 + 1} = (\frac{1}{2} - i\frac{\sqrt{3}}{2}) I_R$$

$$\rightarrow 2\pi i \operatorname{Res}(f(z); e^{i\pi/3}) = I_R + (\frac{1}{2} - i\frac{\sqrt{3}}{2}) I_R + \int_0^{2\pi/3} \frac{i R e^{it}}{R^3 e^{3it} + 1}$$

$$\left| \int_0^{2\pi/3} \frac{i R e^{it}}{R^3 e^{3it} + 1} \right| \leq R \int_0^{2\pi/3} \frac{|dt|}{|R^3 e^{3it} + 1|} \leq \frac{R}{R^3 - 1} \frac{2\pi}{3} (R)$$

$$= \frac{2\pi}{3} \frac{R^2}{R^3 - 1} \rightarrow 0$$

$\Rightarrow R \rightarrow \infty$

So, that is good for us because when we take the limit as R goes to 0 on both sides of this equation this integral tends to 0, this integral tends to 0, so we are left with just these two pieces so in summary.

(Refer Slide Time: 38:13)

$$\frac{1}{|R^3 e^{3it} + 1|} \leq \frac{1}{R^3 - 1}$$

$$2\pi i \operatorname{Res}(f(z); e^{i\pi/3}) = I_R \left(\frac{3}{2} - i\frac{\sqrt{3}}{2} \right)$$

$$\operatorname{Res}(f(z); e^{i\pi/3}) = \frac{1}{(e^{i\pi/3} + 1)(e^{i\pi/3} - e^{i2\pi/3})} = \frac{1}{(\frac{3}{2} + i\frac{\sqrt{3}}{2})(i\sqrt{3})}$$

$$I_R \left(\frac{3}{2} - i\frac{\sqrt{3}}{2} \right) = \frac{2\pi i}{i\sqrt{3} \left(\frac{3}{2} + i\frac{\sqrt{3}}{2} \right)}$$

If we two pi i times the residue of f of z at the point at the point e power I pi by 3 which we can calculate is I R times 1 plus half minus i root 3 by 2, which is 3 by 2 minus I root 3 by 2. So, it is easy to calculate the residue of f at e power i pi by 3, I will just give the value the residue is going to be 1 by e power I pi by 3 its just 1 by e power I pi by 3

minus. So, plus 1 times e power i pi by 3 minus e power i phi pi by 3 and that is going to be 1 by 3 plus 3 by 2 plus I root 3 by 2 times i root 3.

So, I R from by substituting this over there we get I R is equal to I R times 3 by 2 minus I root 3 by 2 is equal to 2 pi i by i root 3 times 3 by 2 plus I root 3 by 2 notice these are conjugates. So, we get the modulus when we multiply then I cancels here and then, so you get I R is equal to 2 pi by the modulus of this complex number here is 3.

(Refer Slide Time: 39:53)

The image shows a digital whiteboard with the following handwritten mathematical work:

$$\operatorname{Res}(f(z); e^{i\pi/3}) = \frac{1}{(e^{i\pi/3} + 1)(e^{i\pi/3} - e^{i\pi/3})} = \frac{1}{(\frac{3+i\sqrt{3}}{2})(i\sqrt{3})}$$

$$\lim_{R \rightarrow \infty} \frac{1}{2\pi i} \int_{\gamma_R} \left(\frac{3-i\sqrt{3}}{2} \right) dz = \frac{2\pi i \cancel{i\sqrt{3}}}{\cancel{i\sqrt{3}} (\frac{3+i\sqrt{3}}{2})}$$

$$\lim_{R \rightarrow \infty} I_R = \frac{2\pi i}{3\sqrt{3}}$$

$$\int_0^{\infty} \frac{dx}{x^4+1} = \frac{2\pi i}{3\sqrt{3}}$$

So, you get three root 3 so that is the value this is I R in limit. So, limit as R goes to infinity, which is what we want. Since, we have already taken the limit for the other integral, so this is integration from zero to infinity of d x by x cube plus 1 is equal to two pi by 3 root 3, okay? So, that is a contour integral an example of contour integral. So, we can use the residue theorem, and and some calculations like this estimations like this in order to calculate real indefinite integrals of some sorts. So, the in this example, I have given the contour already in the problem in the statement of the problem normally the challenge is lies in choosing an appropriate contour for given problem, so here is another example of that sort.

(Refer Slide Time: 41:07)

Eg: Evaluate $\int_{-\infty}^{\infty} \frac{\cos 3x}{(x^2+1)^2} dx$. (using residues)

$f(z) = \frac{\cos z}{(z^2+1)^2}$ is an even function

$$\int_{-\infty}^{\infty} \frac{\cos 3x}{(x^2+1)^2} dx = \lim_{R_1 \rightarrow \infty} \int_{-R_1}^0 \frac{\cos 3x}{(x^2+1)^2} dx + \lim_{R_2 \rightarrow \infty} \int_0^{R_2} \frac{\cos 3x}{(x^2+1)^2} dx$$

So, evaluate integration from minus infinity to infinity of cosine 3 x by x squared plus 1 whole squared d x. So, the idea is using residues, so this function cosine x by x squared plus one whole squared notice is f of x equals this is an even function.

(Refer Slide Time: 43:10)

$f(z) = \frac{\cos z}{(z^2+1)^2}$ is an even function

$$\int_{-\infty}^{\infty} \frac{\cos 3x}{(x^2+1)^2} dx = \lim_{R_1 \rightarrow \infty} \int_{-R_1}^0 \frac{\cos 3x}{(x^2+1)^2} dx + \lim_{R_2 \rightarrow \infty} \int_0^{R_2} \frac{\cos 3x}{(x^2+1)^2} dx$$

$$\lim_{R \rightarrow \infty} \int_{-R}^R \frac{\cos 3x}{(x^2+1)^2} dx = \int_{-\infty}^{\infty} \frac{\cos 3x}{(x^2+1)^2} dx$$

So, I am free to choose C, so I will choose C to be 0. So, that is the definition of this as we know from the analysis, but what is true is that when the function is even one can use these expressions to show that the limit as R goes to infinity of minus R to R of cosine three x by x squared plus 1 whole squared d x a. If we can show that this limit exists then

this is equal to you know this expression on the right hand side, which is actually you know by definition integration from minus infinity to infinity of cosine 3 x d x by x squared plus one whole squared, okay?

So, if we can show that this limit exists and then it has to equal these two when the function is even it has to equal the sum of these two, when the function is even. So, we can calculate this particular given definite improper integral, so we will take this root and try to first take the contour in appropriate function and in appropriate contour to evaluate this particular integral minus R to R cosine 3 x by x squared plus 1 whole squared d x.

(Refer Slide Time: 44:28)

$$f(z) = \frac{e^{i3z}}{(z^2+1)^2} = \left(\frac{\cos 3z}{(z^2+1)^2} + i \frac{\sin 3z}{(z^2+1)^2} \right)$$

$$z^2+1 = (z+i)(z-i)$$

$$2\pi i \operatorname{Res}(f; i) = \int_{\gamma_R} f(z) dz$$

So, that minus R to R suggests that perhaps I have to stick to the real line from minus R to R, but what is the appropriate function. Well let us take f of z equals 1 by z squared plus 1 whole squared owing to the denominator, okay? Then this function or I should say e power three i z by that, so this is going to give me well cosine 3 z by z squared plus 1 whole squared plus i sine 3 z by z squared plus 1 whole squared. So, hopefully if I am able to say something about the integration of this from the real line from minus R to R, I can hopefully say something about its real part.

So, with with lot of that hope we can we will consider this f of z this function f of z this function e power i 3 z is entire, so there is no problem with the numerator, but in the denominator, notice that z squared plus 1 is z plus i times z minus i. So, there is a pole of order 2 at z equals i or minus i, okay? So, if we consider the upper half plane, then there

is only one pole of order two namely i , so if we consider a semicircle like that and then this line on the real line from minus R to R so we take a orientation on this contour. It is a closed simple closed contour, so then the residue by the residue theorem, $2\pi i$ times the residue of f at the point i is going to give us, the integration on the considered contour γ . Let me call this contour γ_1 and γ_2 , again so integral over γ_1 plus γ_2 of $f(z) dz$. We know that limit as R goes to infinity of γ_2 is what we are interested in.

(Refer Slide Time: 46:55)

The image shows a digital whiteboard with the following handwritten content:

$$z+1 = \frac{z+1}{(z+i)(z-i)}$$

$$2\pi i \operatorname{Res}(f; i) = \int_{\gamma_1} f(z) dz + \int_{\gamma_2} f(z) dz$$

$$\int_0^{\pi} \frac{e^{3iRt} R i e^{it} dt}{(R^2 e^{2it} + 1)^2} \quad \gamma_2(t) = R e^{it} \quad 0 \leq t \leq \pi$$

So, this is integration over γ_1 of $f(z) dz$ plus integration over γ_2 of $f(z) dz$. Let me first parameterize γ_2 . γ_2 can be parameterized as $\gamma_2(t) = R e^{it}$ where t goes from 0 to π , okay? So, this is 0 to π , z is $R e^{it}$, so I have $i e^{it}$ power $3 i R R$ power $i t$ and then the differentiation is $R i e^{it} dt$ divided by $z^2 + 1$. $z^2 + 1$ is $R^2 e^{2it} + 1$ whole squared.

(Refer Slide Time: 47:53)

The image shows a digital whiteboard with handwritten mathematical work. At the top, the integral $\int_0^\pi \frac{e^{3iRt} Ric^{it} dt}{(R^2 e^{2it} + 1)^2}$ is written, with a note $v_2(t) = Re^{it} \quad 0 \leq t \leq \pi$. Below this, the modulus of the integrand is bounded: $\leq \int_0^\pi \frac{1 \cdot R |dt|}{(R^2 - 1)^2} = \frac{R}{(R^2 - 1)^2} \pi$. To the right, a note says $\rightarrow 0$ as $R \rightarrow \infty$. Further down, a contour integral is shown: $2\pi i \left(\frac{-i}{e^3} \right) = \int_{-R}^R \frac{e^{3iz}}{(z^2 + 1)^2} dz + \int_{\text{arc}} f(z) dz$. The arc integral is marked with a zero and $\rightarrow 0$ as $R \rightarrow \infty$. Below this, the integral is expressed as $= \int_{-R}^R \frac{\cos 3x + i \sin 3x}{R^2 + 1} dx$.

So, like we saw in the earlier problem, when we consider this in modulus this is less than or equal to the integration from 0 to pi like we saw in the earlier problem the denominator is less than greater than or equal to R squared minus 1 in whole squared. So, that can be done, so this part is okay. And the numerator we have, e power 3 i R e power i t, so if I write e power i t as cosine t plus i sine t, then 3 i R e power i t is going to be 3 i R cosine t minus 3 R sine t.

So, the real part of this complex number is 3 minus 3 R sine t and as t ranges from 0 to pi sign is positive. So, e raised to minus 3 R sine t, which is going to be the modulus of this complex number, the modulus of this complex number is going to be the e raise to the real part of the complex number in the exponent, so this is the modulus of that complex number. So, this is going to be less than or equal to 1. So, this is 1 times R times modulus of i e power of it is 1 modulus of d t. So, this is less than or equal to, well less than, this is equal to R by R squared minus 1 whole squared times certain (()) its pi, the length of that curve and this goes to 0, as R goes infinity.

So, that is what we are interested in. So, then we have 2 pi i times so that the calculation of residue of f at the point I which is a singularity of f inside this contour, is easy. So, that is an exercise that one can see is minus i by e cube. So, using this equation here 2 pi i times the residue of f at i which 2 pi i times the residue of f at i, which is 2 pi i by eq. So, using this equation here 2 pi times the residue of f at i, which is 2 pi i by e q is equal

to integration of gamma 1 that is what we want. It is the integration of minus R to R of cosine sorry, e power 3 by x by x squared plus 1 whole squared d x plus this integral over gamma 2 of, I will just f of z d z.

Now, we are we are interested in limit at R goes infinity and we showed that limit of R goes to infinity, so f of z itself is 0. So, this 0 as R goes to infinity. This is the integral limit as R goes to infinity of this gives us integration infinity to minus infinity of cosine 3 x plus i sine 3 x d x divided by x squared plus 1 whole square. So, on the right hand, on the left side we have 2 pi by e q, which is a real number. So, real and imaginary parts of this indefinite integral converge because there are no imaginary parts on the left hand side. So, indeed the real part of this definite integral, which is minus infinity to infinity of cosine 3 x p x by x square plus 1 whole square is equal to 2 pi by e q. That is how we evaluate this identity.

(Refer Slide Time: 51:41)

The image shows a handwritten derivation on a slide. At the top, it shows an inequality: $\leq \int_0^R \frac{|R| |dt|}{(R^2-1)^2} = \frac{R}{(R^2-1)^2} \pi \cdot \frac{2\pi R - 3R \sin t}{e^{-3R \sin t}}$. Below this, it shows the limit as $R \rightarrow \infty$ of $e^{-3R \sin t} \leq 1$. The main derivation starts with $2\pi i \left(\frac{-i}{e^3} \right) = \int_{-R}^R \frac{e^{3iz}}{(z^2+1)^2} dz + \int_{\gamma} f(z) dz$. As $R \rightarrow \infty$, the second integral vanishes. This leads to $\Rightarrow \frac{2\pi}{e^3} = \int_{-\infty}^{\infty} \frac{\cos 3x + i \sin 3x}{(x^2+1)^2} dx$. Finally, it states $\int_{-\infty}^{\infty} \frac{\cos 3x}{(x^2+1)^2} dx = \frac{2\pi}{e^3}$.

So, as one can see, the challenge in the problem lies in choosing an appropriate function and an appropriate contour for that function in order evaluate a definite integral. One can solve the more examples of these all, and like I mentioned at the beginning of this problem, one can look into the textbook for more example of this all, and evaluate definite integrals using Cauchy's residue theorem. I will pause, stop.
