Calculus of Variations and Integral Equation

Welcome viewers, to the NP-TEL lecture series on the calculus of variations. This is the fifteenth lecture of the series. Recall that in the last lecture, the fourteenth lecture we had considered the functionals with moving boundaries.

(Refer Slide Time: 00:37)

Functionals With Moving
Boundary Points

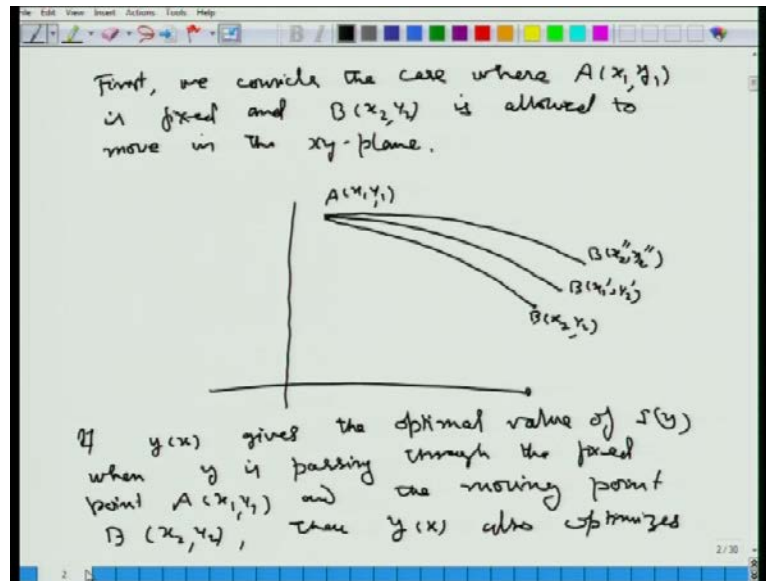

$$I(y) = \int_{x_1}^{x_2} F(x, y(x), y'(x)) dx.$$

$A(x_1, y_1)$ and $B(x_2, y_2)$
are moving in the xy -plane. $y_1 = y(x_1)$
and $y_2 = y(x_2)$.

The diagram shows a coordinate system with a horizontal x -axis and a vertical y -axis. A curve $y(x)$ is drawn between two points $A(x_1, y_1)$ and $B(x_2, y_2)$. The points are labeled with their coordinates, and the curve is labeled $y(x)$. The x -axis is labeled x and the y -axis is labeled y .

Here, the integral we had considered is of simplest type that, $I(y)$ equal to integral x_1 to x_2 of $F(x, y, y')$ dx , where these boundary points $A(x_1, y_1)$ and $B(x_2, y_2)$ can move freely in the xy -plane or they can move in a constrained way that they are moving along a curve.

(Refer Slide Time: 01:03)

In the last lecture, we had started with the introduction of these type of functionals. Here, we had considered first, the case when one of the points let us say the point $A(x_1, y_1)$ is fixed and the point B is moving freely in the xy -plane or moving along a given curve. Here, $B(x_2, y_2)$ moves to neighboring point $B(x_1, y_2)$ and then again it moves to $B(x_2, y_1)$; like that it keeps on moving or it may move along a given curve. As we know, that if the functional is optimized for given points A and B , where A and B are moving then it also gets optimized when those two points were assumed to be fixed.

Therefore, any functional which is optimizing it whether the points are moving or they are fixed, that extremal should be solution of Euler's equation; that is the necessary condition which should always be satisfied. So, we can restrict our consideration of variation of the functional over the family of extremals.

(Refer Slide Time: 02:32)

$I(y)$, if $A(x_1, y_1)$ & $B(x_2, y_2)$ were both fixed. Therefore y must satisfy the necessary condition, i.e., Euler's equation,

$$F_y - \frac{d}{dx} F_{y'} = 0. \quad (14.1)$$
 The equation (14.1) is a second order ODE, hence its general solution is a two parameter family of curves, given by

$$y = y(x, c_1, c_2). \quad (14.2)$$
 since $A(x_1, y_1)$ is specified, one of the constants c_1, c_2 is determined.

Here, you know that this Euler's equation $F_y - \frac{d}{dx} F_{y'} = 0$ is a second order differential equation which gives us the family of extremals as two parameter family of functions, where $y = y(x, c_1, c_2)$; c_1 and c_2 are parameters. And so, we assume that the point $A(x_1, y_1)$ is fixed. Then, one of these two constants gets determined and then we get this sub family $y = y(x, c)$ family of extremals taken as one parameter family; that means, c is given different arbitrary values and we get different extremals here.

(Refer Slide Time: 03:56)

$$\Delta I(y) = \int_{x_1}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx - \int_{x_1}^{x_2} F(x, y, y') dx$$

$$\Delta I(y) = \int_{x_2}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx + \int_{x_1}^{x_2} [F(x, y + \delta y, y' + \delta y') - F(x, y, y')] dx. \quad (14.3)$$

We can consider now I on this sub family. I is a function of x and this c is the constant coming here in the equation 4.2 and then, we have the integral x_1 to x_2 F of x, y, y' plus c y' dx . So, we need to consider this functional only on the sub family of extremals; one parameter sub family of extremals. Then, we consider its increment, δI which is the difference of these two integrals at x_1 to x_2 plus δx_2 F of x, y plus $\delta y, y'$ plus δy dx minus x_1 to x_2 F of x, y, y' dx . Here, we break this integral into two parts: x_2 to x_2 plus δx_2 and x_1 to x_2 . These are written here, x_2 to x_2 plus δx_2 of $F(x, y, y')$ plus $\delta y, y'$ dx plus x_1 to x_2 F of x, y, y' plus $\delta y, y'$ dx minus F of x, y, y' dx and these two integrals are then written like this:

(Refer Slide Time: 04:48)

The first term in (14.3), i.e.,

$$\int_{x_2}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx$$

$$= F(x_2 + \theta \delta x_2, y + \delta y(x_2 + \theta \delta x_2), y' + \delta y'(x_2 + \theta \delta x_2)) \cdot \delta x_2$$

by mean value theorem of integrals.

$$0 < \theta < 1.$$

$$= F(x_2 + \theta \delta x_2, (y + \delta y)(x_2), (y' + \delta y')(x_2)) \delta x_2 + \epsilon_1(\delta y, \delta y')$$

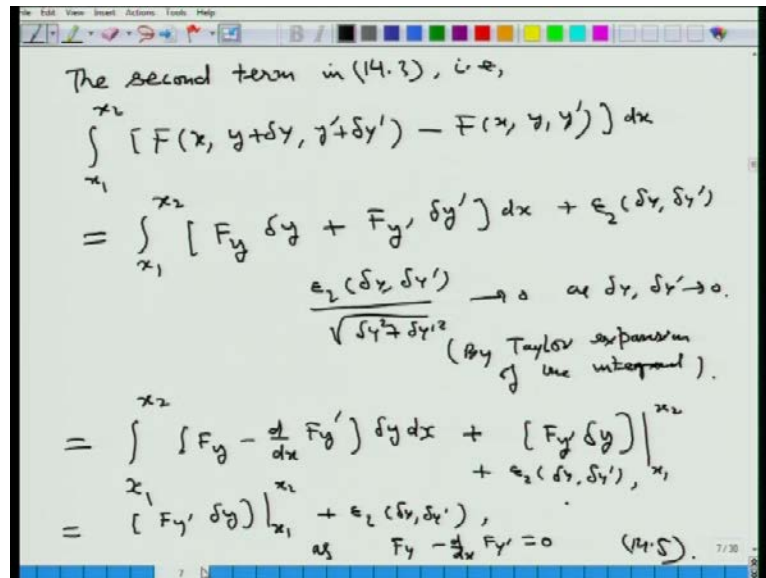

by continuity of F ,

$$\frac{\epsilon_1(\delta y, \delta y')}{\sqrt{\delta y^2 + \delta y'^2}} \rightarrow 0 \text{ as } \delta y, \delta y' \rightarrow 0. \quad (14.4)$$

They are approximated by the mean value theorem and Taylor series expansion. So, first integral is approximated; F evaluated at some intermediate point where θ lies between 0 and 1. F of x_2 plus θ $\delta x_2, y$ plus δy evaluated at x_2 plus θ $\delta x_2, y$ plus δy evaluated at x_2 plus θ δx_2 and θ times δx_2 here. And then, by continuity it is written like F of x_2, y plus δy at x_2, y plus δy at x_2 times δx_2 plus some function ϵ_1 , which is function of δy and $\delta y'$ of higher order in δy and $\delta y'$.

This is the condition required here that $\epsilon \delta y \delta y' / \sqrt{\delta y'^2 + \delta y^2} \rightarrow 0$ as δy and $\delta y'$ tend to 0.

(Refer Slide Time: 06:00)

The second term in (14.3), i.e.,

$$\int_{x_1}^{x_2} [F(x, y+\delta y, y'+\delta y') - F(x, y, y')] dx$$

$$= \int_{x_1}^{x_2} [F_y \delta y + F_{y'} \delta y'] dx + \epsilon_2(\delta y, \delta y')$$

$\epsilon_2(\delta y, \delta y') \rightarrow 0$ as $\delta y, \delta y' \rightarrow 0$.
(By Taylor expansion of the integrand).

$$= \int_{x_1}^{x_2} [F_y - \frac{d}{dx} F_{y'}] \delta y dx + [F_{y'} \delta y] \Big|_{x_1}^{x_2} + \epsilon_2(\delta y, \delta y')$$

$$= [F_{y'} \delta y] \Big|_{x_1}^{x_2} + \epsilon_2(\delta y, \delta y'),$$

as $F_y - \frac{d}{dx} F_{y'} = 0$ (14.5).

Here, the second integral using the Taylor series expansion can be written in this manner that, x_1 to x_2 plus $F_y \delta y$ plus $F_{y'} \delta y'$ dx plus ϵ_2 of the same time as ϵ_1 , and then shifting this derivative on δy here. This derivative here is shifted onto to y' and so, we get this term x_1 to x_2 integral F_y minus $d/dx F_{y'}$ $\delta y dx$ plus the boundary term $F_{y'} \delta y$ evaluated at x_1 to x_2 plus here ϵ_2 which is coming from the top. Here, since y is an extremal, this integrand is 0.

(Refer Slide Time: 06:53)

From (14.4) & (14.5) we get

$$\Delta I(y) = F \Big|_{x=x_2} \delta x_2 + [F_y \delta y] \Big|_{x_1}^{x_2} + \epsilon_3(\delta x, \delta y)$$

$\frac{\epsilon_3(\delta x, \delta y)}{\sqrt{\delta x^2 + \delta y^2}} \rightarrow 0$ as $\delta x, \delta y \rightarrow 0$.

Since $A(x_1, y_1)$ is fixed, we have

$$\delta y(x_1) = 0.$$

Therefore

$$\Delta I(y) = F \Big|_{x=x_2} \delta x_2 + [F_y \delta y] \Big|_{x_1}^{x_2} + \epsilon_3(\delta x, \delta y)$$

We have to find $\delta y(x_2)$.

$$\delta y(x_2) \neq \delta y_2.$$

We are left with this 14.5 and which then gives us delta I the increment of the functional as F evaluated at x 2 times delta x 2 plus F y prime delta y evaluated at x 1 to x 2 plus some epsilon 3 which is sum of epsilon 1 and epsilon 2; since the point A is fixed. So, we get delta y at x 1 is 0. Finally, we get delta I y as F evaluated at x 2 times delta x 2 plus F y prime delta y evaluated at x equal to x 2 plus epsilon 3. Now, here delta y at x 2; we need to calculate that which is we know that delta y at x 2 is not equal to delta y 2.

(Refer Slide Time: 07:45)

Here, in the given figure A is fixed; only B is moving. So, B has moved from this to let us say point C. Here, at x_2 plus δx_2 and y_2 plus δy_2 and this is B x_2 y_2 . Here, we can see that this BL is actually δy at x_2 which is not as δy_2 . And so, we need to calculate this δy at x_2 ; we use here, that BL is MN which is **CN minus MN** CN minus CM.

Here, we approximate this CM by assuming that this is a triangle, since these quantities are small. We assume that these are straight lines and so, CM over LM is approximated to the tangent of ψ where ψ is this angle. We get this as y' evaluated at x_2 and so, we get finally δy equal to δy_2 minus y' at x_2 times δx_2 .

(Refer Slide Time: 09:02)

The handwritten text on the whiteboard reads:

δI , the variation of the functional $I(y)$ is the linear part in the increment, $\Delta I(y)$.

$$\delta I(y) = F \Big|_{x=x_2} \delta x_2 + F_y \Big|_{x_2} (\delta y_2 - y'(x_2) \delta x_2)$$

$$= [F - y' F_y'] \Big|_{x=x_2} \delta x_2 + F_y \Big|_{x_2} \delta y_2 \quad (14.5)$$

The necessary condition, for $I(y)$ to have optimal value of y , is

$$\delta I(y) = 0 \Rightarrow$$

$$[F - y' F_y'] \Big|_{x=x_2} \delta x_2 + F_y \Big|_{x_2} \delta y_2 = 0 \quad (14.6)$$

since δx_2 & δy_2 are independent variations of x_2 & y_2

Using this finally, **we get δI** ; now since this small δI , see here **capital delta is** the increment and small δI is the linear part in the variation linear part in the increment δI and so, dropping those epsilon terms we get finally δI , like this. Here, we collect this $y' F_y$ times δx_2 in the first term and so, we get F minus y' times δx_2 plus y' times δx_2 plus y' times δx_2 .

Finally, we get this variation δI ; small δI which is the linear part in the increment δI like this as 14.5 here. Now, the necessary condition is that this variation must be 0. We get this 14.6 here and now assuming that these δx_2 and δy_2 , that is the increment at the movement in the point x_2 and y_2 . If this

movement is independent, then we see that Δx_2 and Δy_2 can take arbitrary values. If we take Δy_2 as 0 and Δx_2 as 1, we get this $F - y' F_{y'}$ equal to 0. Similarly, if we take Δx_2 equal to 0 and $\Delta y_2 = 1$ in 14.6, we get $F_{y'}$ evaluated at $x = x_2$ equal to 0.

(Refer Slide Time: 10:48)

Handwritten notes on a whiteboard:

Hence $(F - y' F_{y'})|_{x=x_2} = 0$
 $F_{y'}|_{x=x_2} = 0$.

2) The point (x_2, y_2) moves on the curve
 $y = \phi(x)$ then
 $\Delta y_2 = \phi'(x_2) \Delta x_2$. Hence

We get $(F - y' F_{y'})|_{x=x_2} \Delta x_2 + F_{y'}|_{x=x_2} \Delta y_2 = 0$

reduced to $(F - y' F_{y'})|_{x=x_2} \Delta x_2 + \phi'(x_2) F_{y'}|_{x=x_2} \Delta x_2 = 0$
 $F + (\phi' - y') F_{y'}|_{x=x_2} = 0$. (14.7)

So, independent variations of Δx_2 and Δy_2 will lead to this. And, if we have the constant movement that, the point x_2, y_2 moves along a curve given by $y = \phi(x)$, then we see that Δy_2 will be $\phi'(x_2) \Delta x_2$ **sorry this should be Δx_2** . And hence, using this in Δy_2 here we get $F - y' F_{y'} \Delta x_2 + \phi'(x_2) F_{y'} \Delta x_2 = 0$.

Now, again Δx_2 is independent is arbitrary variation of point x_2 and then the coefficient of that must be 0. So, we get this 14.7 which is $F + (\phi' - y') F_{y'}|_{x=x_2} = 0$.

(Refer Slide Time: 11:46)

(14.7) is called the transversality condition.

Example 14.8

$$I(y) = \int_{x_1}^{x_2} f(x, y) \sqrt{1+y'^2} dx$$

in $A(x_1, y_1)$ is fixed and (x_2, y_2) moves
 on $y = \phi(x)$, $f(x, \phi(x)) \neq 0$.

This is the condition known as transversality condition and that is what is used here in this example 14.8; and we take here the point A(x 1, y 1) is fixed and this point (x 2, y 2) is moving on this curve. Here, we need to find that point x 2 such that this extremal y x gives us the optimal value of the functional I(y) defined integral x 1 to x 2 F x y square root of one plus y prime square dx. We assume that the value of F on the points on this curve is not 0.

(Refer Slide Time: 12:31)

$$F + (\phi' - y') F_{y'} \Big|_{x=x_2} = 0$$

$$F = f(x, y) \sqrt{1+y'^2}$$

$$f \sqrt{1+y'^2} + (\phi' - y') \frac{f y'}{\sqrt{1+y'^2}} = 0 \quad \text{at } x=x_2$$

$$f (1+y'^2) + (\phi' - y') f y' = 0 \quad \text{at } x=x_2$$

$$f + f y'^2 + \phi' y' - f y'^2 = 0 \quad \text{at } x=x_2$$

$$f(x_2, \phi(x_2)) \neq 0 \Rightarrow 1 + \phi' y' = 0 \quad \text{at } x=x_2$$

$$\Rightarrow \phi'(x_2) y'(x_2) = -1.$$

Thus at $x=x_2$ extremal $y = y(x)$ must be orthogonal to the curve $y = \phi(x)$.

Using this transversality condition we get $F + \phi' - y' = 0$ at $x = x_2$, which gives us that ϕ' at x_2 is y' at x_2 equal to -1 ; this is the orthogonality condition. So, the transversality condition reduces to the orthogonality condition here; that is what it means that here this point.

Here, this y is tangent to this and tangent to this ϕ that is, ϕ' and y' ; this should be orthogonal. Here it should have the 90 degree angle here; it should hit this. So, So, we should take that x_2 which this tangent to this extremal and tangent to this curve y equal to ϕ must be orthogonal to each other.

(Refer Slide Time: 13:44)

Example 14.9

$$I(y) = \int_{x_1}^{x_2} \frac{\sqrt{1+y'^2}}{y} dx$$

$y(x_1) = 0$ (x_2, y_2) moves on the st. line $y = x - A$.

The transversality condition $F + (\phi' - y') F_{y'} = 0$ at $x = x_2$.

Here $F = \frac{\sqrt{1+y'^2}}{y}$, we get

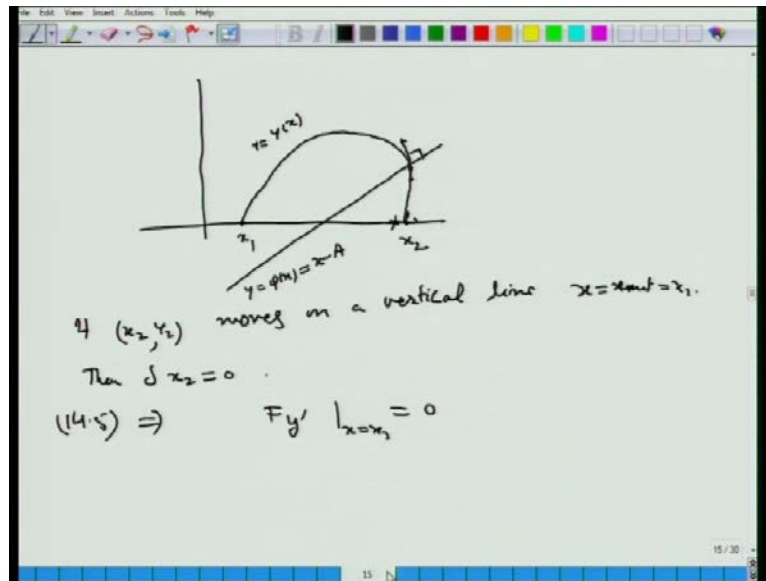

$$\frac{\sqrt{1+y'^2}}{y} + (1 - y') \frac{y'}{\sqrt{1+y'^2}} = 0 \quad \text{at } x = x_2$$

$$1 + y'^2 + (1 - y') y' = 0$$

$$1 + y'^2 + y' - y'^2 = 0 \Rightarrow y' = -1 \quad \text{at } x = x_2.$$

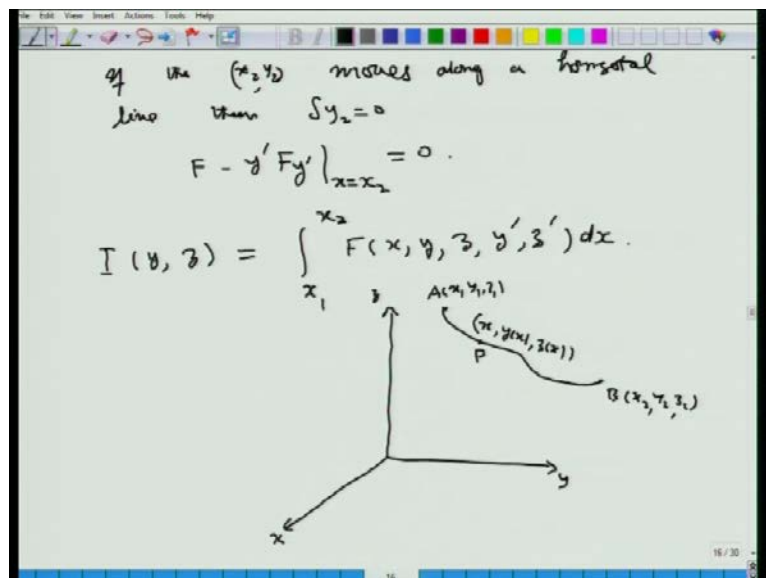

So, in the next example we have taken $I(y)$ equal to x_1 to x_2 integral square root of 1 plus y' square over y and here, y at x_1 equal to 0 and (x_2, y_2) moves on the straight line y equal to x minus A . So, here the transversality condition reduces to y' equal to -1 at x equal to x_2

(Refer Slide Time: 14:08)

Which says that; that means, y equal to minus x . It should be that line and this is y equal to x minus a and therefore, this extremal should hit here on this line at this point x equal to x_2 orthogonally. So, that is what we get here. And if the movement is on vertical line, then we know that then δx_2 must be 0. So, this condition here δx_2 is 0. We are left with $F_{y'}$ evaluated at x_2 $\delta y_2 = 0$. Since δy_2 is arbitrary, we get $F_{y'}$ at x_2 equal to 0. So, that is what is obtained.

(Refer Slide Time: 15:10)

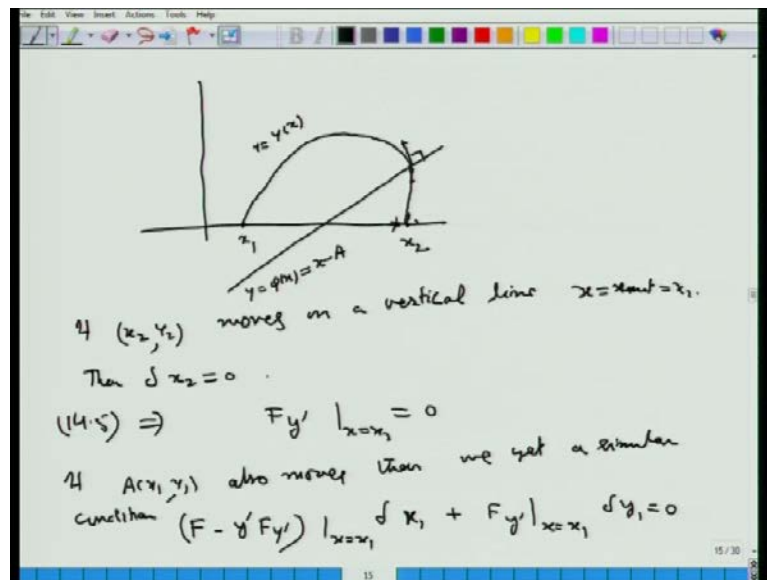

Here, now if the movement is along the horizontal line. If the movement; if x_2, y_2 moves along a horizontal line, then Δy_2 is equal to 0 and we get this again from this equation here. So, Δy_2 is 0. We get F_{y_2} minus y_2 prime F_{y_2} prime evaluated at x_2 equal to x_2 times $\Delta x_2 = 0$. Since Δx_2 is arbitrary, we get the coefficient of this equal to 0 here. So, we get F_{y_2} minus y_2 prime F_{y_2} prime at x_2 equal to x_2 equal to 0; that is what will be used in this case.

Next case we consider is the more general functional like this: $I(y, z) = \int_{x_1}^{x_2} F(x, y, z, y', z') dx$. As we have already seen, that the situation is like this; we have x, y and z here. The point is in three dimension: this A, which is x_1, y_1, z_1 and this B, x_2, y_2, z_2 ; this is the extremal here, which is parameterized at x, y at x and z at x . So, any point p here moving point on this curve will be parameterized here x is the parameter; x itself. So, x, y at x, z at x here that is what earlier we had already explained this.

In this case, both A and B can move or we can take A fixed and B moving. Like this, in the earlier case also we had taken here.

(Refer Slide Time: 18:00)

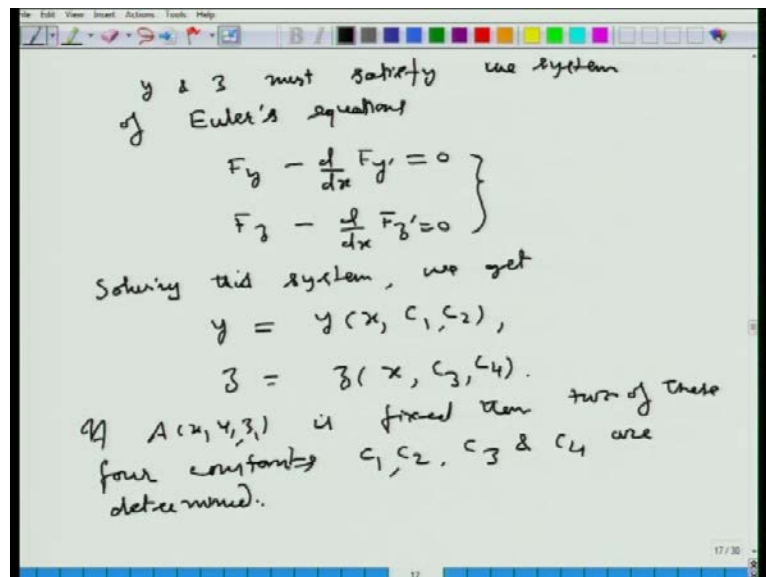

This A is fixed and B is moving. If A is also moving, we get a similar transversality condition at the point A also. If A x_1, y_1 also moves, then we get a similar condition, **transversality similar condition** that is, F_{y_1} minus y_1 prime F_{y_1} prime evaluated at x_1 equal to x_1 delta x_1 plus F_{y_1} prime evaluated at x_1 delta y_1 equal to 0. Since delta x_1

1 and delta y 1 can move freely, then we get the coefficients 0 and if x 1 y 1 also moves along a curve, y equal to psi x; we get a transversality condition there at the point in a similar manner.

So, in the three dimension case also; here, A and B can move freely they can move along a curve and now, there is one more possibility that it can move along a surface also, because here we are in three dimension. We can have this point A or B or both can move freely either along a curve or along two different curves or along two different surfaces. So, we will consider those cases here separately.

(Refer Slide Time: 19:52)

In this same manner this y and z must satisfy the system of Euler's equation $F_y - \frac{d}{dx} F_{y'} = 0$ and $F_z - \frac{d}{dx} F_{z'} = 0$.

Whether the points A and B are moving or they are fixed, this necessary condition must be satisfied. So, we get y solving. The extremals are solving this system, we get y equal to y of x c 1 c 2 and z equal to z of x c 3 c 4. If A is fixed, then two of these four constants c 1, c 2, c 3 and c 4 are determined.

(Refer Slide Time: 21:44)

Then we set

$$y = y(x, C)$$

$$z = z(x, D).$$

Therefore, we consider

$$I(y(\cdot, C), z(\cdot, D))$$

$$= \int_{x_1}^{x_2} F(x, y(x, C), z(x, D), y'(x, C), z'(x, D)) dx.$$

That means, then we get y equal to y of x let us say the parameter we write now C and z as z of x comma D. Therefore, we consider I on these sub families y of C and z D which is integral x 1 to x 2 F of x y x C z x D y prime x c z prime x D dx and the point B moves freely or moves in a curve or in a surface. So, that is what we consider here.

(Refer Slide Time: 23:12)

The increment $\Delta I(y, z)$,

$$\Delta I(y, z) = \int_{x_1}^{x_2 + \delta x_2} F(x, y + \delta y, z + \delta z, y' + \delta y', z' + \delta z') dx$$

$$- \int_{x_1}^{x_2} F(x, y, z, y', z') dx$$

$$= \int_{x_1}^{x_2 + \delta x_2} F(x, y + \delta y, z + \delta z, y' + \delta y', z' + \delta z') dx$$

$$+ \int_{x_1}^{x_2} [F(x, y + \delta y, z + \delta z, y' + \delta y', z' + \delta z') - F(x, y, z, y', z')] dx$$

(15.4).

We consider this increment delta I(y). We will not write the dependents here, but it is understood that these y and z are the solutions of this system of Euler's equation. So, that C and D dependents is always there; which we are not going to write it explicitly. It is

And in the second term we will. Here, first term we use the continuity and this is F evaluated at x equal to x_2 plus let us say $\epsilon_3 \delta x \delta y \delta x'$ plus $\delta y'$. So, clubbing whatever remaining reminder here with this and plus we get x_1 to x_2 ; shifting these derivatives, we get F_y minus d by dx of F_y prime plus F_z minus d by dx of F_z prime δy here and δz times dx and plus the boundary terms; that is F_y prime δy evaluated x_1 to x_2 plus F_z prime δz evaluated at x_1 to x_2 and plus this ϵ_2 there, whatever.

Now, since the functions y and z are solutions of Euler's equation, So, this term is 0 similarly this part of the integrand is 0.

(Refer Slide Time: 30:11)

The image shows a digital whiteboard with handwritten mathematical notes. At the top, there is an equation:
$$= F|_{x=x_2} \delta x_2 + [F_y \delta y]_{x_1}^{x_2} + [F_z \delta z]_{x_1}^{x_2} + \epsilon_5 (\delta x, \delta y, \delta z)$$
 Below this, it says $\delta y(x_1) = 0$ and $\delta z(x_1) = 0$. Then, a note says: "Hence, $\delta I(y, z)$, which is the linear part in the increment $\Delta I(y, z)$, is given by" followed by the equation:
$$\delta I(y, z) = F|_{x=x_2} \delta x_2 + (F_y \delta y)|_{x=x_2} + (F_z \delta z)|_{x=x_2} = 0 \quad (15.5)$$
 Below that, two more equations are written:
$$\delta y(x_2) = \delta y_2 + y'(x_2) \delta x_2, \quad (15.6)$$

$$\delta z(x_2) = \delta z_2 + z'(x_2) \delta x_2.$$

We get finally, this equal to F evaluated at x equal to x_2 plus F_y prime δy evaluated at x equal to x_2 and also, here x_1 to x_2 plus F_z prime δz of this evaluated at x_1 to x_2 plus; let us say, some $\epsilon_5 \delta x \delta y \delta x'$ plus $\delta y'$. Here, all these epsilons are functions of higher order terms in $\delta x \delta y \delta x'$ plus $\delta y'$.

It is of little order o in those terms. Since A is fixed, δy at x_1 is 0 δz at x_1 is 0. Hence, the variation $\delta I(y, z)$ which is the linear part in the increment, $\delta I(y, z)$ is given by $\delta I(y, z) = F|_{x=x_2} \delta x_2 + f_y$ prime $\delta y|_{x=x_2}$ and plus F_z prime $\delta z|_{x=x_2}$ and this should be equal to 0.

Now, here as before this δy at x_2 is not equal to δy_2 and δz at x_2 is not equal to δz_2 . And so, you can see that in the same manner we get δy at x_2 approximately here we write it as $y \delta y_2$ plus y' at x_2 δx_2 . Similarly, δz at x_2 is δz_2 plus z' at x_2 δx_2 . So, let us say this is finally, we got this 15.5 and this is 15.6.

(Refer Slide Time: 33:40)

Using (15.6) in (15.5) we get

$$\delta I(y, z) = (F - y'F_y' - z'F_z') \delta x_2 + F_y'|_{x=x_2} \delta y_2 + F_z'|_{x=x_2} \delta z_2$$

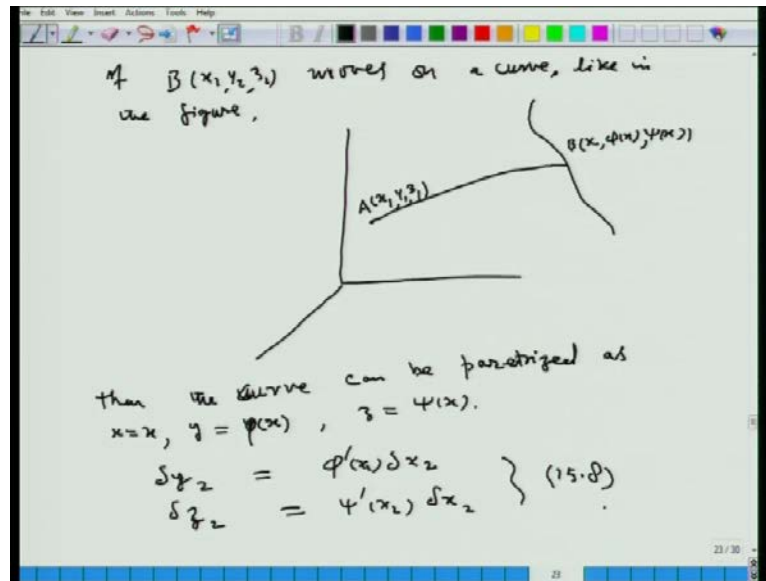

If $B(x_2, y_2, z_2)$ moves freely then $\delta x_2, \delta y_2$ & δz_2 are independent variations. Then, we get

$$\left. \begin{aligned} F - y'F_y' - z'F_z' &= 0 \\ F_y' &= 0 \\ F_z' &= 0 \end{aligned} \right\} \text{ at } x = x_2$$

Using 15.6 in 15.5, we get this δI at y, z equal to F minus y' F_y' minus z' F_z' evaluated at x equal to x_2 δx_2 plus and the second term also, F_y' evaluated at x equal to x_2 δy_2 plus F_z' evaluated at x equal to x_2 δz_2 equal to 0.

So, these terms are coming from here. Substituting this here, we will have a y' δx_2 . Similarly, F_z' δz_2 . So, that is what is clubbed here and plus F_y' evaluated at x equal to x_2 δy_2 plus F_z' evaluated at x equal to x_2 δz_2 equal to 0. Now, if this B which is x_1, x_2, y_2, z_2 moves freely, then this $\delta x_2, \delta y_2$ and δz_2 are independent variations. Then, we get these three conditions F minus y' F_y' minus z' F_z' equal to 0 F_y' equal to 0 F_z' equal to 0 at x equal to 0.

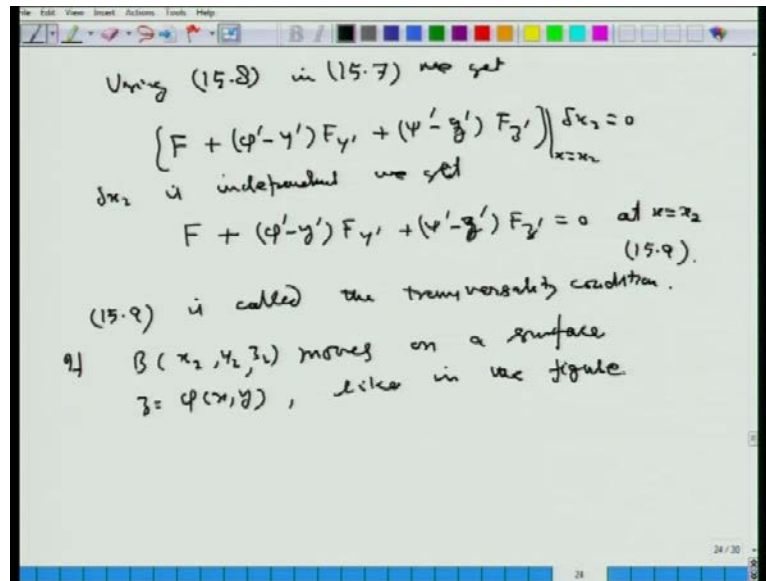

(Refer Slide Time: 36:24)

If this $B \times 2 \times y \times 2 \times z \times 2$ moves on a curve, then **here like in this figure**. So, here A is like this; that is $x_1 \ y_1 \ z_1$ and this B is moving on this curve in three dimension that is parameterized by so like this b is parameterized here $x \ \phi(x) \ \psi(x)$. Then, the curve can be parameterized as y . So, x equal to x ; y equal to $\phi(x)$, and z equal to $\psi(x)$, then you have δy_2 at x_2 will be y' at $x_2 \ \delta x_2$. Similarly, δz_2 at x_2 , this is ϕ' at x_2 and this will be ψ' at $x_2 \ \delta x_2$.

This δy_2 and δz_2 ; these variations will be then given by in terms of δx_2 variations. Because the variations of this δy_2 and δz_2 cannot be independent, they will be given in terms of the variation of x . If x moves, then these $\phi(x)$ and $\psi(x)$ also move. So, these δy_2 and δz_2 will be given by this. Let us say these as 15.7 and 15.8.

(Refer Slide Time: 39:38)

Using 15.8 in 15.7 we get, $F + (\phi' - \gamma') F_y + (\psi' - \delta') F_z$ times δx_2 equal to 0. So, that is what we will get here. Since δx_2 is independent, we get $F + (\phi' - \gamma') F_y + (\psi' - \delta') F_z$ evaluated at $x = x_2$. Here, $F_z = 0$ at $x = x_2$.

So, this is the transversality condition. This is 15.9. 15.9 is called. As before, here this is the general case of the earlier one. Transversality condition; this will be evaluated at $x = x_2$. If point A is also moving we get and if it moves along the curve we get similar thing at $x = x_1$. So, we will have a transversality condition at that point. Now, if the other variation could be like this: $B(x_2, y_2, z_2)$ moves on a surface, this $z = \phi(x, y)$ then.

(Refer Slide Time: 42:36)

Like in the figure, you have this x y z . Here, A is fixed and this is the surface here; this B is moving on this. So, this is x y and z is phi of x y.

So, this will be moving on this; this will be x 2. Let me write this in terms of x 2; this B will be actually x 2 y 2 and phi of x 2 y 2. In this case we get this delta z as phi x delta x plus phi y delta y. Therefore, delta z 2 will be phi x evaluated at x 2 y 2 delta x 2 plus phi y x 2 y 2 to delta y 2. And so, substituting it here; this delta z 2 from this. Here this delta z 2, we substitute here and then collect the terms. So, we get the following ; let us say this is 15.10. Using 15.10 in 15.7, we get this F minus y prime F y prime plus phi x. This should be actually implicit. This one, when we substitute delta z 2 here in the last term, let us put that here. Here, we have F minus y prime F y prime minus z prime F z prime is evaluated at x equal to x 2 plus F y prime evaluated at x equal to x 2 delta y 2 and this F z prime and then here phi x delta x 2 plus phi y delta y 2. All these are evaluated at x equal to x 2. This is evaluated at x 2 and these are evaluated at x 2 y 2. So, this is equal to 0.

Now this will be collected with phi delta x 2. Here, this is delta x 2 ; this delta x 2 will be collected with this and this one will be collected with this.

(Refer Slide Time: 46:44)

The whiteboard shows the following handwritten text:

$$\left[F - y'F_y' + (\phi_x - z')F_z' \right] \delta x_2 + (\phi_y F_y' + F_y') \delta y_2 = 0$$

So δx_2 & δy_2 are independent variations,

$$\text{So } F - y'F_y' + (\phi_x - z')F_z' = 0$$

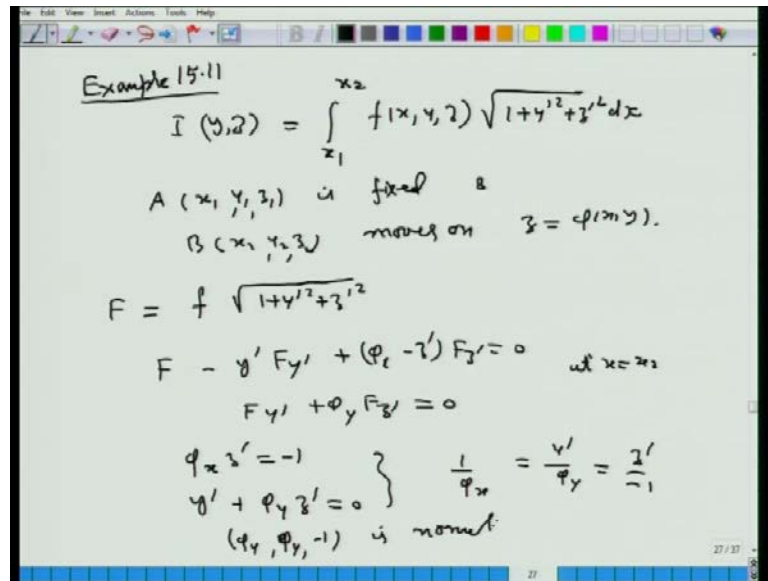

$$F_y' + \phi_y F_z' = 0.$$

We will have $F - y'F_y' + \phi_x F_z' - z'F_z'$ This F_z' with this; like this. $F - y'F_y' + \phi_x F_z' - z'F_z'$. So, this is (0) times δx_2 plus this one; $\phi_y F_y' + F_y'$. So, $\phi_y F_y' + F_y'$ and similarly, this $\phi_x F_z' - z'F_z'$; like this. So, plus $\phi_y F_y' + F_y'$ to δy_2 .

All these are evaluated at x equal to x_2 . This is also evaluated at x equal to x_2 . Now, δx_2 and δy_2 are independent variations. We get $F - y'F_y' + \phi_x F_z' - z'F_z' = 0$ and $\phi_y F_y' + F_y' = 0$. This should have been $\phi_y F_y' + F_y'$; y' here and $\phi_y F_z'$. This is $F_y' + \phi_y F_z'$; this should be equal to 0, because here in this previous one, we have F_z' ϕ_x which comes here in times δx_2 with this. So, we get ϕ_x with plus sign and minus z' ; that is $\phi_x F_z' - z'F_z'$ times δx_2 . And here, we have F_y' and then plus this $\phi_y F_y' + F_y'$ times δy_2 . So, that is what $\phi_y F_y' + F_y'$. This is also evaluated at x equal to 0.

When we have this δx_2 and δy_2 independent variations we get the coefficients 0 here in this case because they are moving freely on the point B on the surface. So, δx_2 and δy_2 will be independent.

(Refer Slide Time: 50:40)

Example 15.11

$$I(y, z) = \int_{x_1}^{x_2} f(x, y, z) \sqrt{1+y'^2+z'^2} dx$$

$A(x_1, y_1, z_1)$ is fixed $B(x_2, y_2, z_2)$ moves on $z = \phi(x, y)$.

$$F = f \sqrt{1+y'^2+z'^2}$$

$$F - y' F_{y'} + (\phi_x - z') F_{z'} = 0 \quad \text{at } x = x_2$$

$$F_{y'} + \phi_y F_{z'} = 0$$

$$\left. \begin{aligned} \phi_x z' &= -1 \\ y' + \phi_y z' &= 0 \end{aligned} \right\} \frac{1}{\phi_x} = -\frac{y'}{\phi_y} = \frac{z'}{-1}$$

$(\phi_y, \phi_y, -1)$ is normal

So, let us consider this example here. This one will be then number 15.11. So, $I(y, z)$ is the general case of the earlier one x_1 to x_2 f of x, y, z square root $1 + y'$ square plus z' square dx . So, here $A(x_1, y_1, z_1)$ is fixed and $B(x_2, y_2, z_2)$ moves on the surface $z = \phi(x, y)$. Here in this case, we have F equal to little f times one plus y' times square plus z' square. Here, the condition $F - y' F_{y'} + (\phi_x - z') F_{z'} = 0$ and $F_{y'} + \phi_y F_{z'} = 0$ at $x = x_2$ gets translated to this $\phi_x z' = -1$ and $y' + \phi_y z' = 0$. So, these two solving this we get $1/\phi_x = -y'/\phi_y = z'/-1$. This, we see that this $\phi_x, \phi_y, -1$ is the normal to surface and this $1, y', z'$ is normal to the surface, $z = \phi(x, y)$ and $1, y', z'$ is tangent to the extremal.

So, due to the lack of time we will be finishing in the next lecture. Thank you very much for viewing this.
