

# Calculus of Variations and Integral Equation

Prof: Dharendra Bahuguna

Prof: Malay Banerjee

Department of Mathematics and Statistics

Indian Institute of Technology, Kanpur

## Module #01

## Lecture #16

Welcome viewers to the NPTEL lectures series on the calculus of variations. This is the 16th lecture in the series. Recall that in the last lecture, we had considered various cases of the functional where the points A and B can move. They can move freely in this space or they can move in a constraint way. If A and B are in a plane, then they can move along curves. Or if A and B are in three dimension space they can move either along curves or on surfaces.

(Refer Slide Time: 00:59)

Example 15.11

$$I(y, z) = \int_{x_1}^{x_2} f(x, y, z) \sqrt{1+y'^2+z'^2} dx$$

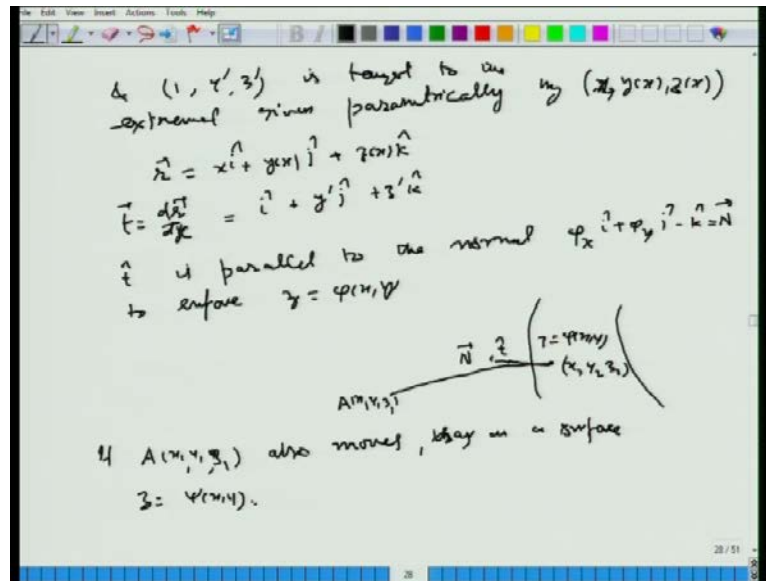

$A(x_1, y_1, z_1)$  is fixed &  
 $B(x_2, y_2, z_2)$  moves on  $z = \phi(x, y)$ .

$$F = f \sqrt{1+y'^2+z'^2}$$
$$F - y' F_{y'} + (\phi_x - z') F_{z'} = 0 \quad \text{at } x = x_2$$
$$F_{y'} + \phi_y F_{z'} = 0$$
$$\left. \begin{aligned} \phi_x z' &= -1 \\ y' + \phi_y z' &= 0 \end{aligned} \right\} \quad \frac{1}{\phi_x} = \frac{y'}{\phi_y} = \frac{z'}{-1}$$

$(\phi_y, \phi_x, -1)$  is normal to the surface  $z = \phi(x, y)$

So, in the last part of the last lecture, we had stopped at these example 15.11, where we considered the functional  $I(y, z) = \int_{x_1}^{x_2} f(x, y, z) \sqrt{1+y'^2+z'^2} dx$ .

(Refer Slide Time: 02:51)

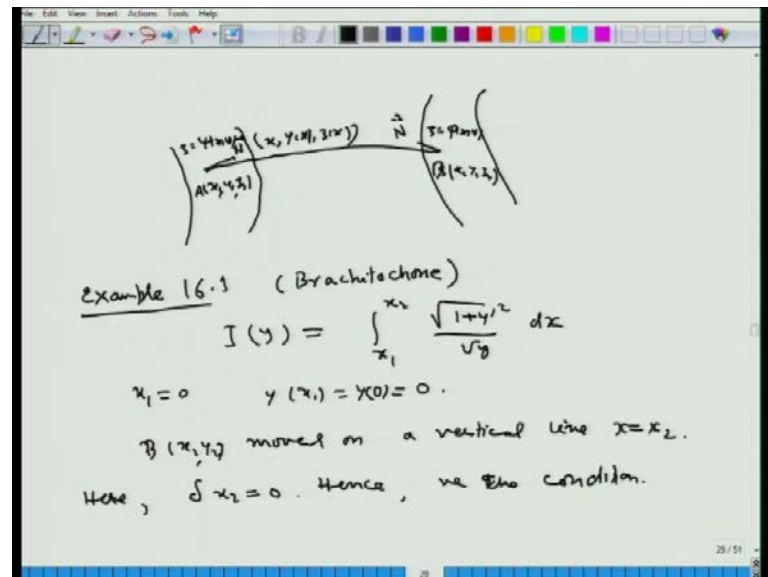

Here, this point A is taken to be fixed. That is in three dimensional space, A having coordinates  $x_1, y_1, z_1$  and B having coordinates  $x_2, y_2, z_2$ , where the point B is moving on the surface given by  $z$  equal to  $\phi$  of  $x, y$ . So, here the integrand is capital F, which is given by small  $f$  times square root of  $1$  plus  $y'$  square plus  $z'$  square. And the condition here is the following that  $f$  minus  $y'$  prime  $F y'$  prime plus  $\phi_x$  minus  $z'$  prime  $F z'$  prime equals to  $0$  and  $f$  of  $y'$  prime plus  $\phi_y$   $F z'$  prime equals to  $0$  add the other end  $x$  equal to  $x_2$ . And so, these conditions imply that  $\phi_x$   $z'$  prime equal to minus  $1$  and  $y'$  prime plus  $\phi_y$   $z'$  prime equal to  $0$ .

Solving these for  $z'$  prime, we get here  $z'$  prime by minus  $1$  equal to  $1$  over  $\phi_x$  and solving it for  $z'$  prime we get  $z'$  prime over minus  $1$  equal to  $y'$  prime over  $\phi_y$ . So, this is what we get that  $1$  over  $\phi_x$  equal to  $y'$  prime over  $\phi_y$  equal to  $z'$  prime over minus  $1$ . Here, we see that this  $\phi_y$   $\phi_x$   $\phi_y$  minus  $1$  is the normal to is the normal to the surface  $z$  equals to  $\phi(x, y)$  and  $1 y'$  prime  $z'$  prime is tangent to the extremal given by given parametrically by  $y, x, z$  of  $x$  and therefore, the tangent will have. So, here the position factor on this is given by  $x$  plus  $y$  which is function of  $x$  and  $z$  of  $x$  like this. So, the tangent here will be  $d\vec{r}$  by  $dx$  which will be  $\hat{i}$  plus  $y'$   $\hat{j}$  plus  $z'$   $\hat{k}$ .

So, this is what is tangent to the extremal and here what it says at this tangent is parallel to so, this tangent  $\vec{t}$  is parallel to the normal that is  $\phi_x \hat{i} + \phi_y \hat{j} - \hat{k}$  to the surface  $z$  equal to  $\phi(x, y)$ . So, here this is the surface that is given by  $z$  equal to  $\phi(x, y)$

and at this point this  $x_2, y_2$  and  $z_2$  here, this extremal is such that, this tangent here at this point is actually parallel to the normal. So, they are in the same direction. Here,  $t$  as well this  $n$ , which is this one normal to the surface. That means, here the extremal, this is the point at which is  $x_1, y_1$  and  $z_1$  it is here at this point  $x_2$  to surface orthogonal.

(Refer Slide Time: 06:07)

So, that is the result which we have got in the earlier case also and the in the case of the when  $x_2, y_2, z_2$  moves along a curve there also we got the orthogonality condition and here also we get the similar condition here. So, if this  $A, x_1, y_1, z_1$  also moves, then say on a surface  $z$  equal to  $\phi(x, y)$ . So, we here we get this situation that this is the surface  $z$  equal to  $\psi(x, y)$  and  $A$  is here that is  $x_1, y_1, z_1$  is moving on the surface and we have this another surface here that is  $z$  equal to  $\phi(x, y)$  and  $B$  is moving on this  $x_2, y_2, z_2$ .

So, this extremely joining this, that is  $(x, y, x, z, x)$  will be such that here also we have the orthogonality condition and here also we have will have orthogonality condition. The tangent here will be parallel to the surface and here also we will get the similar condition. Now, let us take the case, where this example this we will call 16.1. Here, the brachitochone functional, that is  $I(y)$  equal to integral  $x_1$  to  $x_2$  square root  $1$  plus  $y'$  prime square over root  $y$   $dx$ . And here we take  $x_1$  equal to  $0$  and  $y$  at  $x_1$ , which is  $y$  at  $0$  equal to  $0$  and this point  $x_2$ . Here, so, the point  $B$  which is  $x_2, y_2, z_2$  moves on a vertical line, which is given by  $x$  equal to  $x_2$  the constant  $x_2$ .

(Refer Slide Time: 08:34)

$$\delta I(y) = (F - y'F_{y'})|_{x=x_2} \cdot \delta x_2 + F_{y'}|_{x=x_2} \delta y_2 = 0$$

$$\delta x_2 = 0 \quad \text{and } \delta y_2 \text{ is arbitrary, we get}$$

$$F_{y'}|_{x=x_2} = 0.$$

$y(x)$  must satisfy  $F_y - \frac{d}{dx} F_{y'} = 0$ .  
 If the parametric form, we get the extremal as  

$$x = c_1 (t - \sin t)$$

$$y = c_1 (1 - \cos t)$$

$F = \frac{\sqrt{1+y'^2}}{\sqrt{y}}$       The condition  

$$F_{y'}(x_2) = 0 \Rightarrow$$

$$y'(x_2) = 0.$$

So, in this case here  $\delta x_2$  will be 0. Hence, we get hence, the conditions that the variation  $\delta I$  here it is a function of  $y$  only, which is  $F$  minus  $y$  prime  $F_{y'}$  prime evaluated at  $x$  equal to  $x_2$  because here the point is fixed. Only  $b$  is moving plus times  $\delta x_2$  here plus  $F_{y'}$  prime evaluated at  $x$  equal to  $x_2$   $\delta y_2$  equal to 0. And since  $\delta x_2$  is 0 and  $\delta y_2$  is arbitrary, we get  $F_{y'}$  prime evaluated at  $x$  equal to  $x_2$  equal to 0. So, that is what we get here. In this case, we know that here the extremal are here,  $y$  of  $x$  must satisfy this  $F_y$  minus  $d$  by  $d x$  of  $F_{y'}$  prime equal to 0, which gives us in the parametric form.

We get the extremal as  $x$  equal to this we had already solved,  $t$  minus  $\sin t$  and  $y$  equal to  $c_1$  minus  $\cos t$ . And so, here  $F_{y'}$  prime here since  $f$  is here root  $1$  plus  $y$  prime square over root  $y$ . So, the condition  $F_{y'}$  prime at  $x_2$  equal to 0 implies that  $y$  prime at  $x_2$  equal to 0.

(Refer Slide Time: 11:15)

The image shows a digital whiteboard with handwritten mathematical derivations. The derivations are as follows:

$$y' = \frac{\dot{y}}{\dot{x}}$$

$$= \frac{\sin t}{1 - \cos t}$$

$$y'(x_2) = 0 \Rightarrow \sin t = 0$$

$$x_2 = c_1 \pi \Rightarrow c_1 = \frac{x_2}{\pi}$$

$$t = n\pi$$

$$t = \pi$$

$$x = \frac{x_2}{\pi} (t - \sin t)$$

$$y = \frac{x_2}{\pi} (1 - \cos t)$$

At the top right, there are additional notes:

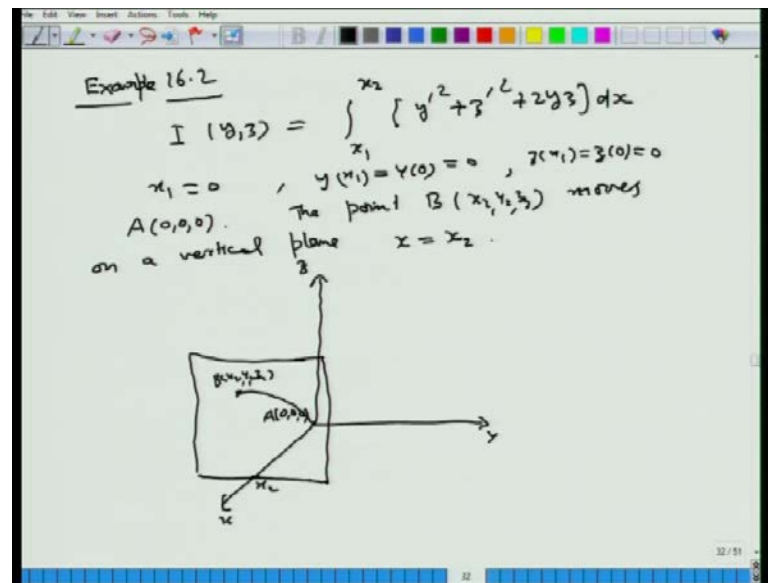

$$y' = \frac{dy}{dx}$$

$$\dot{y} = \frac{dy}{dt}, \text{ etc.}$$

Now, here  $y'$  which is actually  $y$  dot upon  $x$  dot. Dot means  $d$  by  $d t$  and prime means here  $y$  prime means  $d$  by  $d x$  and  $y$  dot equal to  $d$  by  $d t$  etcetera. Here, so, this is what will give us this will be  $\sin t$  over  $1 - \cos t$ . And so,  $y'$  at  $x_2$  equal to 0 implies that  $\sin t$  must be equal to 0. And so, we get  $t$  equal to  $n\pi$  and so, we get here  $x_2$ . So,  $x$  from here the first equation, we get  $t$  equal to  $n\pi$  so,  $x$  equal to  $c_1 \pi$ . So, the first solution we will take  $t$  equal  $n$  equal to 1. So, if we take  $n$  equal to 1, we get  $t$  equal to  $\pi$  and so,  $x$  equal to  $c_1 \pi$  and this imply that  $c_1$  equal to  $x$  over  $\pi$ .

And so, we get  $x$  equal to sorry  $x_2$  here  $x_2$  equal to  $c_1 \pi$  and so,  $c_1$  equal to  $x_2$  over  $\pi$ . So,  $x$  equal to  $x_2$  over  $\pi$   $t - \sin t$  and  $y$  equal to  $x_2$  over  $\pi$   $1 - \cos t$ . So, that is what we will get the extremely in terms of  $x_2$  here.

(Refer Slide Time: 13:17)

Now, the second case where  $F$  is a function of  $y$  and  $z$ , we get the following. So, that is the next example 16.2. So, this we take as  $I$  of  $y z$  equal to  $x_1$  to  $x_2$   $y$  prime square plus  $z$  prime square plus  $2 y z$   $dx$  and here again we take  $x_1$  equal to 0 and  $y$  at  $x_1$  which is  $y$  at 0 equal to 0 and  $z$  at  $x_1$  that is  $z$  at 0 equal to 0. So,  $a$  is actually  $(0, 0, 0)$  here and these point and point  $b$  which is  $x_2 y_2 z_2$  moves on a vertical plane, that is  $x$  equal to constant. So,  $x$  equal to  $x_2$ . So, here this is the following picture we have  $x y$  and  $z$ . So, as is here that is  $(0, 0, 0)$  and we have  $x$  equal to  $x_2$  here.  $x_1$  is 0 so, plane like this. So, this point  $B$  is here that is  $x_2 y_2 z_2$  this point  $B$  is on this vertical plane given by this.

(Refer Slide Time: 15:34)

The system of Euler's equations,

$$\left. \begin{aligned} F_y - \frac{d}{dx} F_{y'} &= 0 \\ F_z - \frac{d}{dx} F_{z'} &= 0 \end{aligned} \right\} \Rightarrow$$

$$\begin{aligned} y^{(4)} - y &= 0, \\ z &= y' \end{aligned}$$

$$\begin{aligned} y(x) &= c_1 e^x + c_2 e^{-x} + c_3 \cos x + c_4 \sin x, \\ z(x) &= c_1 e^x + c_2 e^{-x} - c_3 \sin x + c_4 \cos x. \end{aligned}$$

$y(0) = 0$  and  $z(0) = 0 \Rightarrow$

$$\begin{aligned} c_1 + c_2 + c_3 &= 0 \\ c_1 + c_2 - c_3 &= 0 \end{aligned} \Rightarrow \begin{aligned} c_3 &= 0 \\ c_1 &= -c_2 \end{aligned}$$

So, here we get first this system. So, this system of Euler's equation  $F_y$  minus  $d$  by  $dx$  of  $F_{y'}$  equal to 0.  $F_z$  minus  $d$  by  $dx$  of  $F_{z'}$  equal to 0 implies that,  $y$  fourth derivative minus  $y$  equal to 0 and  $z$  equal to  $y$  double prime. So, this solution of this system is the following that is  $c_1 e$  to the power  $x$ . So,  $y$  equal  $c_1 e$  to the power  $x$  plus  $c_2 e$  to the power minus  $x$  plus  $c_3 \cos x$  plus  $c_4 \sin x$ . And since  $z$  equal to  $y$  double prime, so,  $z$  is  $c_1 e$  to the power  $x$  plus  $c_2 e$  to the power minus  $x$  minus  $c_3 \sin x$  plus  $c_4 \cos x$ .

Now, here this  $y(0)$  equal to 0 and  $z(0)$  equal to 0 imply that  $c_1$  plus  $c_2$  plus  $c_3$  equal to 0 and  $c_1$  plus  $c_2$  minus  $c_3$  equal to 0. So, adding these will imply  $c_3$  is 0 and  $c_1$  equal to minus  $c_2$ .

(Refer Slide Time: 17:43)

Handwritten mathematical derivation on a digital whiteboard:

$$y(x) = 2c_1 \left( \frac{e^x - e^{-x}}{2} \right) + c_4 \sinh x$$

or  $y(x) = A \sinh x + B \cosh x$ ,  
 $z(x) = A \sinh x - B \cosh x$ .

At  $x = x_2$ , we have

$$(F - y'F_y, -z'F_z) \Big|_{x=x_2} \delta x_2 + F_y \Big|_{x=x_2} \delta y_2 + F_z \Big|_{x=x_2} \delta z_2 = 0$$

since  $\delta x_2 = 0$  and  $\delta y_2, \delta z_2$  are arbitrary,  
 we have

$$\left. \begin{aligned} F_y &= 0 \\ F_z &= 0 \end{aligned} \right\} \text{ at } x = x_2.$$

$\Rightarrow y'(x_2) = 0, z'(x_2) = 0.$

Write  $y(x)$  as,  $2c_1 \left( \frac{e^x - e^{-x}}{2} \right) + c_4 \sinh x$ . Similarly,  $z(x)$  can be written in the hyperbolic form. So,  $A$  will change these constants  $c_1, c_2$  to  $A$  and  $B$ . So,  $A \sinh x + B \cosh x$  and  $z(x)$  is then  $A \sinh x - B \cosh x$ . Now, for at  $x$  equal to  $x_2$ , we have the condition that  $F - y'F_y - z'F_z$  evaluated at  $x$  equal to  $x_2$  plus  $F_y$  evaluated at  $x$  equal to  $x_2$  delta  $y_2$  plus  $F_z$  evaluated at  $x$  equal to  $x_2$  delta  $z_2$  equal to 0.

Now, since  $\delta x_2$  is 0 and  $\delta y_2, \delta z_2$  are arbitrary variation, we get  $F_y$  equal to 0 and  $F_z$  equal to 0 at  $x$  equal to  $x_2$ . So, these 2 imply that  $y'$  at  $x_2$  equal to 0 and  $z'$  at  $x_2$  equal to 0. Now, here  $y'$  at  $x_2$  will be  $A \cosh x$  and  $z'$  at  $x_2$  will be  $A \sinh x - B \cosh x$  at  $x$  equal to  $x_2$ .

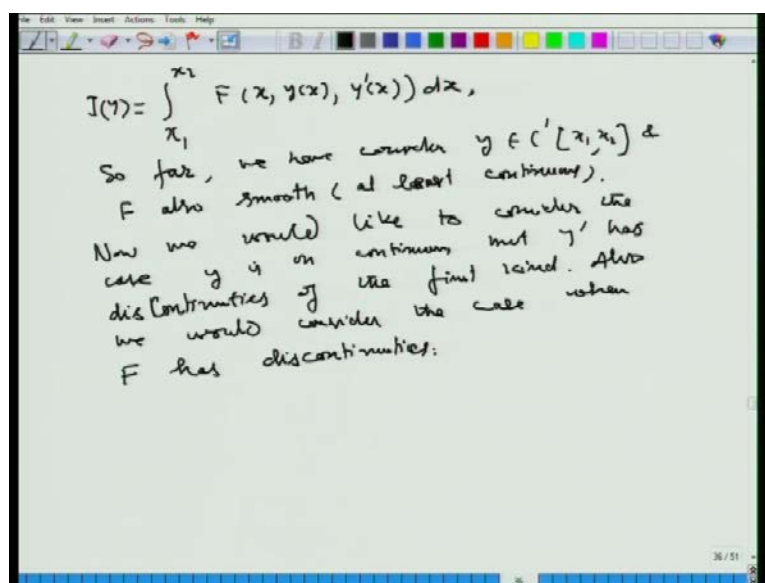

(Refer Slide Time: 20:29)

$$\begin{aligned}
 y'(x) &= A \cos x + B \sin x = 0 \\
 z'(x) &= A \cos x - B \sin x = 0 \\
 \text{subtracting, we get } &2B \sin x = 0 \\
 \cos x \neq 0 \Rightarrow &B = 0 \Rightarrow A = 0 \\
 \Rightarrow &y = 0, z = 0. \\
 \text{If } \cos x = 0, \text{ i.e., } &x = (2n+1)\frac{\pi}{2}, \\
 A = 0 \Rightarrow &y = B \sin x, \text{ where } B \text{ is arbitrary.} \\
 &z = -B \sin x, \\
 \text{In this case } &I(y, z) = \int_0^{(2n+1)\frac{\pi}{2}} (2B^2 \cos^2 x - 2B^2 \sin^2 x) dx \\
 &= 2B^2 \int_0^{(2n+1)\frac{\pi}{2}} \cos 2x dx \\
 &= 2B^2 \left[ \frac{\sin 2x}{2} \right]_0^{(2n+1)\frac{\pi}{2}} = 0
 \end{aligned}$$

If that is so,  $y'$  is actually  $a \cos x + b \sin x$ . So, at  $x = 2$  you get this if this implies to be 0 and similarly,  $z'$  at  $x = 2$  is  $a \cos x - b \sin x$  equal to 0. So, subtracting this we will get  $2b \sin x = 0$  and so, subtracting we get  $B \cos x = 0$  equal to 0. So, if  $\cos x \neq 0$ , this would imply that  $B = 0$  and then this would also imply  $a = 0$  and so,  $y$  identically 0 and  $z$  identically 0 will be the solution. And if  $\cos x = 0$ , that is  $x = 2n\pi + \pi$ , then in this case, we get the extremals  $y = a \cos x$  and here  $y$  becomes  $B \sin x$  and  $z$  equal to  $-B \sin x$ , where  $B$  is arbitrary.

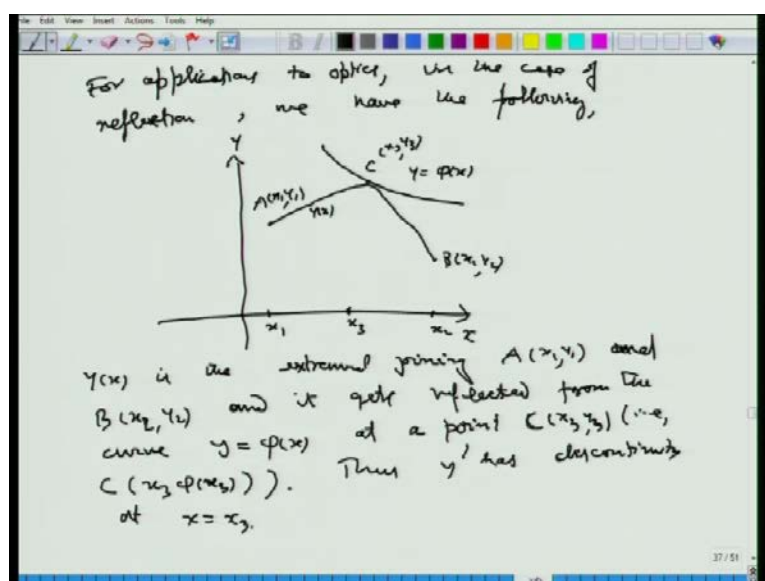

But in this case this  $I(y, z)$  turns out to be 0 since we get 0 to  $x = 2$ . Here is  $2n\pi + \pi$  and we get  $y'$  here and substituting  $y$  and  $z$  here, we get  $2B^2 \cos^2 x - 2B^2 \sin^2 x$  which gives us  $2B^2 \int_0^{2n\pi + \pi} \cos 2x dx$  of. Here, this is  $\cos 2x$  gives us  $\cos 2x dx$  and integrating gives us  $2B^2 \sin 2x$  evaluated at 0 to  $2n\pi + \pi$  and so, this will be 0. Because here  $2x$  will make it  $2n\pi + 2\pi$  and  $\sin$  will be at 0 there and at 0 also this  $\sin$  is 0. So, we get this extremal the value of the extremal at any of those points  $x = 2$  given by  $2n\pi + \pi$  equal to 0.

(Refer Slide Time: 24:11)

So, that was the case we had considered in the last lecture. Now, what we considered here were function we have considered this functional  $I y$  equal to  $x_1$  to  $x_2 F(x, y(x), y'(x)) dx$ . So, far we have considered  $y$  to be  $C^1$  on this  $x_1$  to  $x_2$  and  $f$  also smooth at least continuous. Now, we would like to consider the cases where this  $y$  is only continuous and, but,  $y'$  has discontinuities of the first kind. Also, we would consider the case when  $f$  has discontinuities.

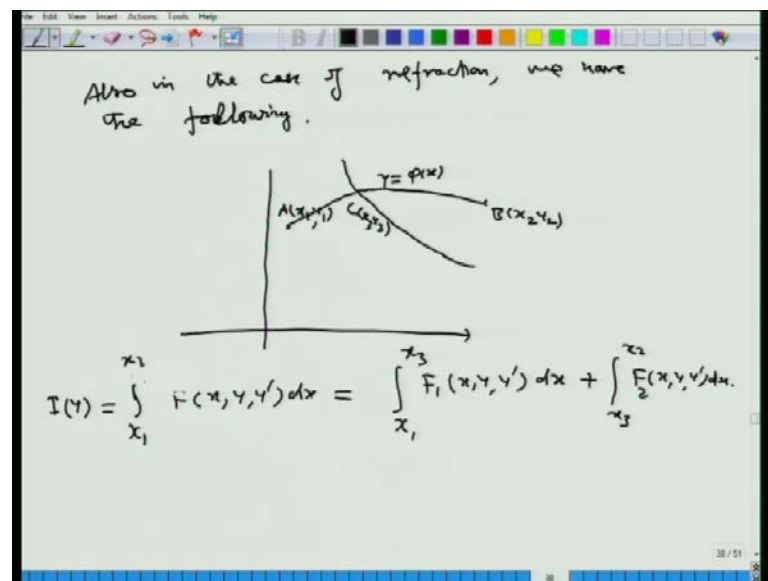

(Refer Slide Time: 26:11)

Here, for applications to optics, in the case of reflection, we have the following. That is here you have some curve here like which is given by  $y$  equal to  $\phi(x)$  and we have these 2 points A which is  $x_1, y_1$  and B  $x_2, y_2$ . These are fixed, but, then here like light ray goes here and get reflected, and then it goes to point B. So, there is a point c that is  $x_3, y_3$  on this which will be moving on this curve  $y$  equal to  $\phi(x)$ . So, here this extremely this is the extremely  $y(x)$  which joins these 2 points. So,  $y(x)$  is the extremely joining a  $x_1, y_1$  to a and b  $x_2, y_2$  and it gets reflected from the curve  $y$  equal to  $\phi(x)$  at moving point c, at point c which is  $x_3, y_3$ . That is here c is  $x_3$  and  $\phi(x_3)$ .

So, obviously, here thus  $y$  has  $y'$  has discontinuity at  $x$  equal to  $x_3$ . So, here this is  $x_1$ , here this is  $x_2$  and this point is  $x_3$  here. So, which is the abscissa of the point c and  $y_3$  is the ordinate of this point c. So, c is moving here. So, this ray goes here somewhere here and hit gets reflected and joins this. So, like that the c can move on this curve and we need to see that for this extremum  $y$  it here, what is that, it optimizes our functional given by this.

(Refer Slide Time: 30:00)

So, that is what is to be considered here and also in the case of refraction, we have the following. That is here again you have a curve like this which is  $y$  equal to  $\phi(x)$  and A is here  $x_1, y_1$  and B point is on the other side. So, this curve goes like this and then joins this B, which is  $x_2, y_2$  and this point C is again on the curve  $y$  equal to  $\phi(x)$  which is  $x_3, y_3$ . So, here it is goes to C and then refracted and goes to B. Here, there is a one

medium on this side, which here A C is considered and C B is considered in other medium and so, this  $f$  will be  $f$  on here. So, we will have up to A to C. So, this  $I_y$  here will be  $x_1$  to  $x_3$   $x_1$  to  $x_2$   $f$  of  $x y$  prime  $dx$ , will then have to be broken in this way.  $x_1$  to  $x_3$   $F_1$  of  $x y$  prime  $dx$  plus  $x_3$  to  $x_2$   $f$  of  $F_2$  of  $x y$  prime  $dx$ .

Because here this is a different medium and the on the other side of this curve, we have a different median. And then these integrants will be involving velocities of the light ray in one medium. And at the other time, on the other side, it will be involving velocity of the light ray in the other medium, which will be different and will apply this thing to those refraction cases. Also, there can be discontinuities in the derivative of the extremul in other ways, which we will explain through some examples. So, let us consider the first case the reflection.

(Refer Slide Time: 32:43)

Reflection:

$$I(y) = \int_{x_1}^{x_2} F(x, y, y') dx$$

$$= \int_{x_1}^{x_3} F(x, y, y') dx + \int_{x_3}^{x_2} F(x, y, y') dx.$$

$$= I_1(y) + I_2(y)$$

$$\delta I(y) = \delta I_1(y) + \delta I_2(y)$$

$$\delta I(y) = (F - y' F_{y'})|_{x=x_3} \delta x_3 + F_{y'}|_{x=x_3} \delta y_3$$

$(x_3, y_3)$  moves on  $y = \phi(x)$ , we get

$$\delta I_1(y) = F + (\phi' - y') F_{y'}|_{x=x_3} \delta x_3.$$

So, in the reflection case we have  $I_y$  given by  $x_1$  to  $x_2$   $f$  of  $x y$  prime  $dx$  and this is to be then since  $y$  prime has discontinuities. So, at  $x_3$  so, we break it  $x_1$  to  $x_3$   $f$  of  $x y$  prime  $dx$  plus  $x_3$  to  $x_2$   $F$   $x y$  prime  $dx$ . And so, here if we call this as  $I_1 y$  and plus  $I_2 y$  and so, the variation of this  $I_y$   $\delta I_y$  will be  $\delta I_1 y$  plus  $\delta I_2 y$ . That will be the newer part in the increments of this and it will have the linearity property. And so,  $\delta I_1$  here you see that it is the case like earlier this part,  $I_1$  involves integral up to A  $x_1$  to  $x_3$ .

So, here  $c$  is moving on this curve. So, it is like our earlier case. So, we can apply this  $\delta I_1$  will be then  $f$  minus  $y$  prime  $F y$  prime evaluated at  $x$  equal to here. So, here the points  $A$  and  $B$  are fixed, only the point  $C$  is moving. And so, that is what we have that  $x_3$  times  $\delta x_3$  plus  $y$   $F y$  prime. Here, we will have to take this  $x_3$  this here  $y$  prime has discontinuities at  $C$ . We will have to take the left limit and here we will have to take the right limit. So, we will write  $x_3$  minus denoting that we will take the left limit here. Similarly,  $x_3$  minus  $\delta x_3$  this thing that is  $\delta I_1$  and similarly, here  $\delta I_2$  this  $y$  will have since here the direction is reversed.

Here, we are going from  $A$  to  $C$  here, we will be moving from  $C$  to  $B$  and so, the direction is reversed. We get minus sign here minus  $f$  of  $n$  here. So, here since this  $y_3$  since  $x_3 y_3$  moves on  $y$  equal to  $\phi x$  we get  $\delta I_1 y$  is  $f$  plus  $\phi$  prime minus  $y$  prime  $F y$  prime evaluated at  $x$  equal to  $x_3$  minus into  $\delta x_3$  because  $\delta y_3$  then will be in terms of  $\delta x_3$  as before.

(Refer Slide Time: 36:47)

$$\delta I_2(y) = - [F + (\phi' - y') F_{y'}] \Big|_{x=x_3+}$$

$$\delta I(y) = \delta I_1(y) + \delta I_2(y) = 0$$

$$\Rightarrow [F + (\phi' - y') F_{y'}] \Big|_{x=x_3-} = F + (\phi' - y') F_{y'} \Big|_{x=x_3+} \quad (16.3)$$

Example 16.4  $I(y) = \int_{x_1}^{x_2} f(x, y) \sqrt{1+y'^2} dx$ .

(16.3), in this case  $\Rightarrow$

$$f(x_2, y_2) \sqrt{1+(y'(x_2))}^2 + (\phi'(x_2) - y'(x_2)) \frac{f(x_2, y_2) y'(x_2)}{\sqrt{1+(y'(x_2))}^2}$$

$$= f(x_2, y_2) \sqrt{1+(y'(x_2))}^2 + (\phi'(x_2) - y'(x_2)) \frac{f(x_2, y_2) y'(x_2)}{\sqrt{1+(y'(x_2))}^2}$$

And similarly, we get  $\delta I_2$  at  $y$  as minus here because direction is reversed.  $f$  plus  $\phi$  prime minus  $y$  prime  $f$  of  $y$  prime evaluated at  $x$  equal to  $x_3$  plus and so, the condition is that  $\delta I y$  equal to 0 means  $\delta I_1 y$  plus  $\delta I_2 y$  equal to 0, which gives us the condition that  $f$  plus  $\phi$  prime minus  $y$  prime  $F y$  prime evaluated at  $x$  equal to  $x_3$  minus must be equal to  $f$  whole thing  $f$  plus  $\phi$  prime minus  $y$  prime  $F y$  prime evaluated at  $x$  equal to  $x_3$  plus. So, this is the condition we get here. Now, so, let us see this example.

This is 6.3, we can use. So,  $y$  is  $x_1$  to  $x_2$  of  $x y \sqrt{1 + y'^2} dx$  and here the situation is that we have a curve like that, which is already explained here. That we have this A here and B here and there is a curve from which, this extremely is getting reflected. So, in this case we get using this let us call it 16.3 like this and this as 16.4. So, 16.3 in this case imply that,  $f$  at  $x_3 y_3 \sqrt{1 + y'^2}$  plus  $y'$  at  $x_3$  minus square plus; this  $\phi$  and all they are continuous. So,  $x_3 \phi'$  is also continuous, only  $y$  is  $y$  prime is having discontinuous.

So,  $y'$  at  $x_3$  minus into  $F$  at  $x_3 y_3 y'$  at  $x_3$  minus divided by square root  $1 + y'^2$  prime at  $x_3$  minus Whole Square. This thing is equal to  $f$  at  $x_3 y_3 \sqrt{1 + y'^2}$  prime at  $x_3$  plus square putting this square here plus  $\phi'$  prime at  $x_3$  minus  $y'$  at  $x_3$  plus  $f$  at  $x_3 y_3 y'$  at  $x_3$  plus divided by square root  $1 + y'^2$  prime at  $x_3$  plus whole square.

(Refer Slide Time: 41:01)

Now, to assume that, this  $f$  of  $x \phi$   $x$  as before, we assume that this is not equal to 0. So, we can divide by this and so, this implies that  $1 + \phi' y'$  over square root  $1 + y'^2$  at  $x$  equal to  $x_3$  minus equal to  $1 + \phi' y'$  over root  $1 + y'^2$  square evaluated at  $x$  equal to  $x_3$  plus. So, that is the condition we get here. So, if we denote here so, from this we want to derive these standard laws of reflection and refractions. So, let us consider the case here. So, I have to draw the figure. So, that this is

the curve  $y$  equal to  $\phi x$ . So, here the tangent to this let us say this makes the angle  $\alpha$  here.

So, this angle is  $\alpha$  and this curve from going from A has tangent here. So, makes let us say the angle  $\beta_1$  and this curve going here, so, B here. So, let us say this tangent makes angle  $\beta_2$  here on the  $x$  axis. So, we see that the angle of incident will be so, let us say this  $\alpha$ . So,  $\tan \alpha$  is  $\phi'$  at  $x_3$  and  $\tan \beta_1$  is  $y'$  at  $x_3$  minus and  $\tan \beta_2$  equal to  $y'$  at  $x_3$  plus. So, this is the point C this is the point  $x_3$ . Here this is of course, the point  $x_1 y_1$  this is the point  $x_2 y_2$  like that.

(Refer Slide Time: 43:38)

$$\frac{1 + \tan \alpha \tan \beta_1}{-\sec \beta_1} = \frac{1 + \tan \alpha \tan \beta_2}{\sec \beta_2}$$

$$- [\cos \beta_1 \tan \alpha + \sec \alpha \sin \beta_1] = [\cos \beta_2 \tan \alpha + \sec \beta_2 \sin \alpha]$$

$$- \cos (\alpha - \beta_1) = \cos (\alpha - \beta_2)$$

$$\pi - (\alpha - \beta_1) = \alpha - \beta_2$$

$$\Rightarrow \text{The angle of incidence} = \text{The angle of reflection.}$$

So, this is the point abscissa of  $c$  which is given by  $x_3$ . Now, using these notations, we see that putting it here  $1 + \phi'$ . So, we have  $1 + \phi'$  means then at  $x_3$  is  $\tan \alpha$ . And you get  $\tan \beta_1$  over you get minus  $\sec \beta_1$  equal to  $1 + \tan \alpha \tan \beta_2$  over  $\sec \beta_2$ . So, multiplying by  $\cos \beta_1$  and here and  $\cos \beta_2$  there and cross multiplying it gives us the following that is or taking it up there as  $\cos \beta_1$ . So, you get minus  $\cos \beta_1$  plus  $\tan \alpha$  here, that we can write as  $\sin \alpha$  and  $\cos \alpha$ . And multiplying by  $\cos \alpha$  both the sides, you get  $\cos \alpha$  plus  $\sin \alpha \sin \beta_1$  equal to  $\cos \beta_2 \sin \alpha$  here and plus  $\cos \beta_2 \cos \alpha$  plus  $\sin \beta_2 \sin \alpha$  like this.

So, this can be written as minus  $\cos$  of  $\alpha - \beta_1$  equal to  $\cos$  of  $\alpha - \beta_2$ . So, this means that  $\pi - \alpha - \beta_1$  equal to  $\alpha - \beta_2$ . So,

here alpha minus, you look at the figure, which we had drawn. This alpha minus beta 2 gives us this angle here and similarly, alpha minus beta alpha minus beta 1 gives us this 1 and alpha minus beta 2 will give us this angle which will be then taken more than as phi minus that thing. So, we get this pie minus alpha minus beta 1 equal to pie alpha minus beta 2. So, here angles so, this actually implies that the angle of incident equal to the angle of reflection, which is the famous law of reflection here. Now, we go to the case, where we have refraction here.

(Refer Slide Time: 46:38)

The image shows a handwritten derivation on a digital whiteboard for the refraction case. The word "Refraction" is written at the top. The integral  $I(y) = \int_{x_1}^{x_2} F(x, y, y') dx$  is split at  $x_3$  into  $I_1(y) = \int_{x_1}^{x_3} F_1(x, y, y') dx$  and  $I_2(y) = \int_{x_3}^{x_2} F_2(x, y, y') dx$ . The variation  $\delta I(y) = \delta I_1(y) + \delta I_2(y)$  is then calculated. For  $\delta I_1(y)$ , the boundary at  $x_3$  is moving, leading to a term  $(F_1 - y'(F_1)_{y'})|_{x=x_3} \delta x_3 + F_1|_{x=x_3} \delta y_3$ . For  $\delta I_2(y)$ , the boundary at  $x_2$  is fixed, leading to a term  $-(F_2 - y'(F_2)_{y'})|_{x=x_2} \delta y_2$ . The final result is  $\delta I(y) = 0$ .

$$\begin{aligned} \text{Refraction} \\ I(y) &= \int_{x_1}^{x_2} F(x, y, y') dx \\ &= \int_{x_1}^{x_3} F_1(x, y, y') dx + \int_{x_3}^{x_2} F_2(x, y, y') dx \\ &= I_1(y) + I_2(y) \\ \delta I(y) &= \delta I_1(y) + \delta I_2(y) \\ \delta I_1(y) &= [F_1 - y'(F_1)_{y'}]_{x=x_3} \delta x_3 + F_1|_{x=x_3} \delta y_3 \\ \delta I_2(y) &= -[F_2 - y'(F_2)_{y'}]_{x=x_2} \delta y_2 \\ \delta I(y) &= 0 \end{aligned}$$

So, in the refraction case, we get  $I(y)$  as integral  $x_1$  to  $x_2$   $F(x, y, y')$   $dx$  will then be having 2 parts  $x_1$  to  $x_3$   $F_1(x, y, y')$   $dx$  plus  $x_3$  to  $x_2$   $F_2(x, y, y')$   $dx$ . So, here in the previous case, this  $F$  is having a cert standard form which will consider now in the second case. So, then we considered this  $\delta I(y)$  again this will be  $I_1(y)$  in this way and  $I_2(y)$ . And so,  $\delta I(y)$  will be  $\delta I_1(y)$  plus  $\delta I_2(y)$  and here, so,  $\delta I_1(y)$  because now,  $x$  that point at which is a  $x_1, y_1$  which is fixed, only this point  $x_3, y_3$  is moving. Similarly, here  $x_2$  is fixed and only this  $x_2, y_2$  is fixed and  $x_3, y_3$  is moving.

(Refer Slide Time: 50:55)

$$y_3 = \phi(x_3) \Rightarrow$$

$$\left[ F_1 + (\phi' - y')(F_1) y' \right] \Big|_{x=x_3^-}$$

$$= \left[ F_2 + \phi' y' (F_2) y' \right] \Big|_{x=x_3^+}$$

Example 16.5

$$I(y) = \int_{x_1}^{x_2} f(x, y) \sqrt{1+y'^2} dx$$

$$f_1 \frac{1+\phi' y'}{\sqrt{1+y'^2}} \Big|_{x=x_3^-} = f_2 \frac{1+\phi' y'}{\sqrt{1+y'^2}} \Big|_{x=x_3^+}$$

$$y'(x_1) = \tan \beta_1, \quad y'(x_2) = \tan \beta_2$$

$$\phi'(x_1) = \tan \alpha, \quad \frac{\phi'(1-\beta_1)}{\phi'(1-\beta_2)} = \frac{f_2}{f_1}$$

So, we get as before here that is  $F_1$  minus  $y'$  prime  $F_1$   $y'$  prime this evaluated at  $x$  equal to  $x_3$  into  $\Delta x_3$  and plus the minus here, same way because direction is reverse and  $s_3$  here.  $F_1$  minus  $y'$  prime at  $F_1$   $F_2$  sorry no  $F_2$   $y'$  prime evaluated to  $x$  equal to  $x_3$  plus  $\Delta x_3$ . We have  $x_3$  plus 1 sorry here, we have one more term  $\Delta y_3$  plus  $F y'$  prime evaluated  $x$  equal to  $x_3$  minus  $\Delta y_3$   $\Delta I_1$ . And similarly,  $\Delta I_2$   $y$  is  $F_2$  minus  $y'$  prime  $F_2$   $y'$  prime. Here, will minus sign it will be plus  $\Delta x_3$   $\Delta y_3$  with the whole of minus sign. So, this also we write minus here.

So, this substituting it here so,  $\Delta I y$  will be then equated to 0. So, we will have these things here and we get since now,  $\Delta y_3$  will be written in terms of here, this  $\Delta y_3$  will be since  $y_3$  is  $x_3$   $y_3$  is moving. So,  $\Delta I y$  equal to 0, gives us the condition that and since  $y_3$  equal to  $\phi$  of  $x_3$ .

(Refer Slide Time: 53:30)

$$f_1 = \frac{1}{v_1} \quad f_2 = \frac{1}{v_2}$$

$$\frac{c_2(x - \beta_1)}{c_2(x - \beta_2)} = \frac{v_1}{v_2}$$

$$\frac{\sin\left(\frac{x}{v_1} - (x - \beta_1)\right)}{\sin\left(\frac{x}{v_2} - (x - \beta_2)\right)} = \frac{v_1}{v_2} \quad \text{Snell's law of refraction.}$$

So, this implies that we get  $F_1 + \phi' - y'$  of  $F_1 y'$ . This thing evaluated at  $x$  equal to  $x_3$  minus equal to  $F_2 + \phi' - y'$  of  $F_2 y'$   $x$  equal to  $x_3$  plus. So, that is the required condition now. So, in this example 16.5, we have this integral  $I y$  equal to  $x_1$  to  $x_2$  of  $x y \sqrt{1 + y'^2} dx$  gives us. That same way, we get  $F_1 + \phi' y'$  over  $\sqrt{1 + \phi'^2 y'^2}$ , evaluated at  $x$  equal to  $x_3$  minus equal to  $F_2 + \phi' y'$  over  $\sqrt{1 + \phi'^2 y'^2}$  evaluated at  $x$  equal to  $x_3$  plus.

And so, here using the same notation that  $y'$  at  $x_3$  is  $\beta_2$   $x_3$  minus is  $\beta_1$   $y'$  at  $x_3$  plus as  $\beta_2$  and  $\phi'$  at  $x_3$  equal to  $\tan \beta_1$  and  $\beta_2$ . So, this is  $\tan \beta_1 \tan \beta_2$  and this is an  $\alpha$ . We get same way that  $\cos$  now,  $\cos$  of  $\beta_1 \cos$  of  $\alpha - \beta_2$  equal to  $\cos$  of  $\alpha - \beta_2$  comes out to be, here, this  $F_2$  divided by  $F_1$ . And so, here in this case the this  $F_1$  is  $1$  over velocity  $v_1$  and  $F_2$  is  $1$  over  $v_2$  we get this  $\cos \alpha - \beta_1$  over  $\cos \alpha - \beta_2$  equal to  $v_1$  over  $v_2$ , which is the Snell's law. Because this can write it as  $\sin \phi_2 - \alpha - \beta_1$  over  $\sin \phi_2 - \alpha - \beta_2$  equal to  $v_1$  over  $v_2$ , which is the Snell's law of refraction.

So, we stop here and in the next one, we will consider more cases of the discontinuities of the extremals. Thank you very much for viewing this.
