Lecture No. # 19

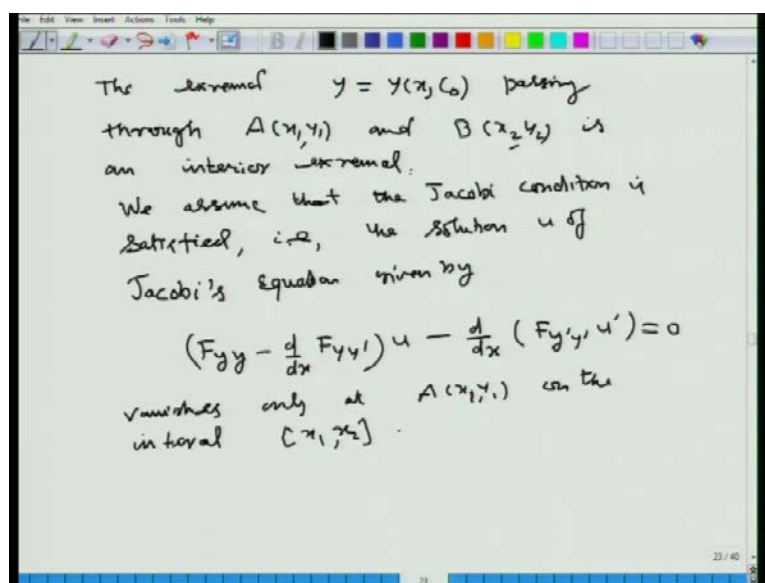

Welcome viewers to the NPTEL lecture series on the calculus of variations. This is the 19th lecture of the series.

(Refer Slide Time: 00:28)

Recall that in the last lecture, we considered a functional of the type $I(y)$ equal to integral from x_1 to x_2 of $F(x, y(x), y'(x)) dx$, subject to the conditions that the point, the functional to y_2 . So, we have the situation here that the point A , which is having coordinates (x_1, y_1) is having a central field here at this point. So, we have the extremals going like this and we assume that the extremals are given as y equal to y of x c . So, this is the family of extremals (no audio from 01:25 to 01:33) forming. So, the one parameter family (no audio from 01:38 to 01:46) y equal to y of x , c , where c is the parameter forms a central extremal field at the point $A(x_1, y_1)$.

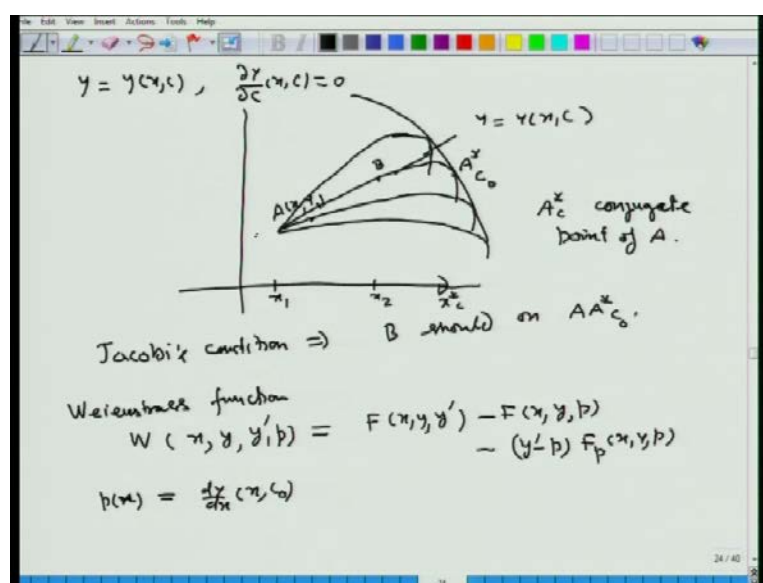

(Refer Slide Time: 02:17)

And the extremal y equal to $y(x, c_0)$ passing through $A(x_1, y_1)$ and $B(x_2, y_2)$ is an interior extremal (no audio from 02:47 to 02:55) So that means, here this extremal, which is $A, B(x_2, y_2)$. So, this is the extremal here, which is having the equation y equal to $y(x, c_0)$. So, for the fixed value of c equal to c_0 , we have this extremal passing through these two points A and B , and this extremal is not on the boundary. So, it is an interior extremal.

And so, here this family of extremals like this forms a central field at the point A . So, we assume that **that** the Jacobi condition is satisfied, that is the solution u of the Jacobi equation, Jacobi's equation, given by $F_{yy} - \frac{d}{dx} F_{yy'}$ times u minus $\frac{d}{dx} F_{y'y'} u'$ equal to 0, **u y prime** equal to 0, vanishes only at the point $A(x_1, y_1)$ and only at (x_1, y_1) on the interval x_1 to x_2 close. So, that means, at that point B does not vanish.

(Refer Slide Time: 05:22)

And so, we have like the situation here, that if we consider c discriminant curve, and so we have in addition to this point, there is an envelope like this, so that the extremals are going like this, and touching it tangentially like this (no audio from 05:47 to 05:54) and so, this point here, **so this point here**, supposing that this is the extremal A star c . So, for given this **this** is the extremal y equal to $y(x, c)$. And so, this A star c , which is on **on** the extremal passing through the point A , and having a intersection having tangential point here on the envelop of this family. The envelop of this family is given as y equal to $y(x, c)$, and $\frac{\partial y}{\partial c}(x, c) = 0$.

So, here it is called c discriminant curve and the point certainly is on the c discriminant curve, other than this, there is the envelop of this family, if it exist, then we have the situation that the extremals from this center point of the central field will be having a points **(())** points here on the extremal.

So, the point on any extremal given by $y(x, c)$ is called conjugate point, which is there on the extremal as well as on the envelope. So, that is called conjugate point of A . So, the **Jacobi condition is** Jacobi's condition implies that B , here this B point should be here. So, B should be on $AA^* c_0$ here. So, that is what we have for c equal to c_0 , we are there on this, so, A star c_0 like this.

So, that is the Jacobi condition means that the Jacobi equation has the solution u , which vanishes only at this point, and then this point A star is c_0 . And therefore, it does not

vanish before, so, x^2 is here, so this **this** here on x , so that is let say, x^*c here, which is the access of this point A^*c0 .

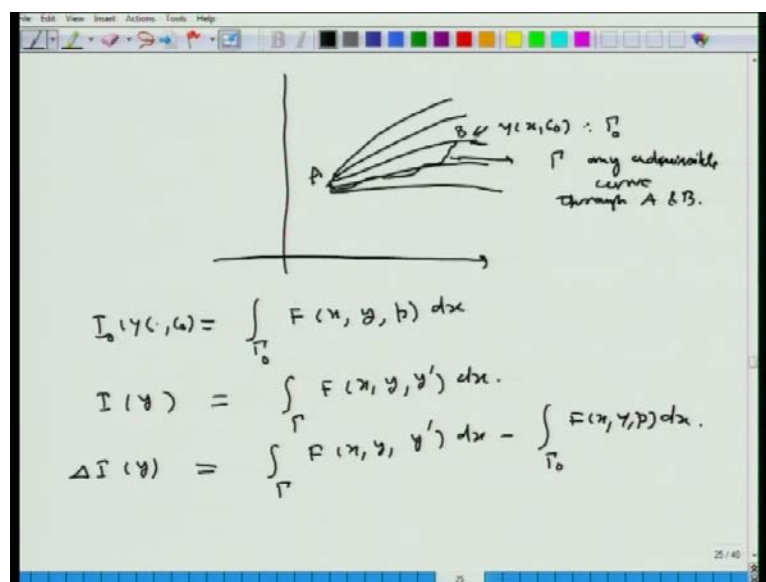

So, x^2 should be such that; it should be prior to this x^*c . So, that is the Jacobi condition, which we had considered earlier then we considered the Weierstrass Function, this Weierstrass

(No audio from 08:58 to 09:08)

Function $W(x, y, y', p)$, which we defined as $F(x, y, y') - F(x, y, p) - y'(p - F_p(x, y, p))$, here p is actually p of x is dy/dx ($x, c0$).

So, that means, on the extremal, we denote this y' equal to p , which is the extremal $y(x, c0)$. So, we want to test whether this extremal satisfy certain conditions, which are called sufficient condition, which will ensure the functional I to have either minimum or maximum. So, we will see that under what conditions, we have the, at maximum value of the functional I , and under what other conditions on the minimum value of the function.

(Refer Slide Time: 10:30)

So, we have seen that here, we considered the following situation here, we have this extremals going like this from A, and here we have this B here. And so, this is the extremal $y(x, c0)$ and we consider any other curve, admissible curve. So, we will call this $y(x, c0)$ as gamma. So, this we denote as gamma 0 and this curve gamma any admissible curve through A and B.

And then, we consider this I_0 of that is $y(x, 0)$ which is x_1 to x_2 . So, we will write that as over γ_0 F of x, y and here y' is p . And $I(y)$ any other curve y , admissible curve like this F of x, y , and y' dx , then we consider this $\delta I(y)$, which is the difference of these two $\gamma_0 F$ of $x, y, y' dx$ minus $\gamma_0 F$ of $x, y, p dx$.

(Refer Slide Time: 12:27)

Handwritten notes on a digital whiteboard:

If $y = y(x, 0)$ is fixed then $I_0(y(x, 0))$ is a function of (x_1, x_2) moving on the extremal $y = y(x, 0)$ and we have

$$dI_0(x, y) = (F - pF_p) dx + F_p dy$$

i.e., $(F - pF_p) dx + F_p dy$ is exact hence the integral $\int (F - pF_p) dx + F_p dy$ is path independent. Therefore

$$\begin{aligned} \int_{\gamma} (F - pF_p) dx + F_p dy &= \int_{\gamma_0} (F - pF_p) dx + F_p dy \\ &= \int_{\gamma_0} \left[(F - pF_p) + F_p \frac{dy}{dx} \right] dx \\ &= \int_{\gamma_0} (F - pF_p + pF_p) dx = \int_{\gamma_0} F(x, y, p) dx \end{aligned}$$

Observing that we have on, if that y equal to $y(x, c)$ is fixed, then this I or other we take one this I_0 is fix then this $I_0(y)$, which is $y(x, c)$ is actually a function of (x_2, y_2) moving on the extremal y equal to $y(x, c)$. And we have seen and we have this d of I_0 at let say (x_2, y_2) , we guide as general (x, y) moving on the extremal then you have seen that this is actually F minus $p F_p$ evaluated at general point $(x, y) dx$ plus $p dy$.

And so, this is therefore, this is exact function here, that is F minus $p F_p dx$ plus $F_p dy$ is exact, hence the integral this over x_1 to x_2 F or n on any curve $\gamma_0 F$ minus $p F_p dx$ plus $F_p dy$ is path independent. Therefore, we have seen that this $\gamma_0 F$ minus $p F_p dx$ plus $F_p dy$ is same thing as $\gamma_0 F$ minus $p F_p dx$ plus $F_p dy$, and then on this, we write this as $\gamma_0 F$ minus $p F_p$, and taken this dx is taken out. So, F_p then dy by dx , which is p here, which is over $\gamma_0 F$ minus $p F_p$ plus $p F_p dx$. So, this cancels. So, you get for $\gamma_0 F$ which is $x, y, p dx$.

(Refer Slide Time: 16:05)

$$\begin{aligned}
 \Delta I(y) &= \int_{\Gamma} F(x, y, y') dx - \int_{\Gamma_0} F(x, y, p) dx \\
 &= \int_{\Gamma} F(x, y, y') dx - \int_{\Gamma} [F(x, y, p) - p F_p(x, y, p) + F_p(x, y, p)] dx \\
 &= \int_{\Gamma} [F(x, y, y') - F(x, y, p) - (y' - p) F_p(x, y, p)] dx \\
 &= \int_{\Gamma} W(x, y, y', p) dx.
 \end{aligned}$$

$W = 0$ on $y = y(x, c_0) \Rightarrow \Delta I(y, c_0) = 0$
 And $\Delta I(y) \geq 0$ if $W \geq 0$ for any value of y' .
 If y' then we get strong min.
 If y' close to p then we get weak min.

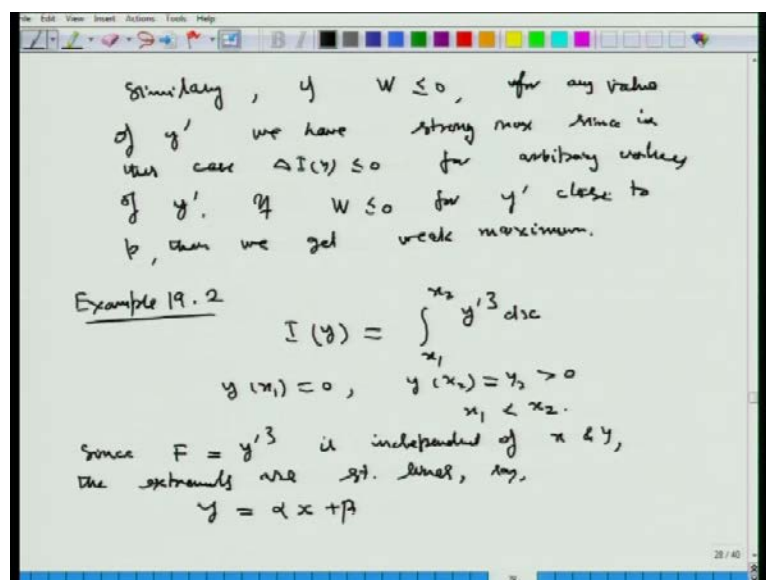

And so, we can therefore, we have seen that this delta I (y) which is the difference in gamma F x, y, p sorry y prime dx minus gamma 0 F x, y, p dx and that using this previous result here, we get this as gamma F x, y, y dash dx minus. Now, we can write from here this is same thing as on gamma. So, on gamma 0 F x, y, p is same thing as this. So, let us call this as 19.1. And so, using that 19.1 this integral, second integral can be written as gamma, integration over gamma F x, y, p minus p F x, y, p dx, here F minus p F p dx F minus p F p dx plus F p x, y, p dy . And so, this we would write as F x, y, y dash taking dx out, and on gamma here dy by dx is y prime. So, we get this F x, y, p minus this y prime minus, minus will make it plus, so minus of this F p x, y, p dx. So, this is what is our, Weierstrass Function x, y, y prime, p d x.

So, we see that this delta I (y), we know that W here, this W is 0 on y (x, c 0), because on this y prime is p. So, you get y prime equal to p and here also y prime is p. So, both the terms will be 0. And delta I (y) will be greater than equal to 0, if W is greater than equal to 0, and so, we will have I I (y). So, that is implies... So, it means that I is delta I (y, c 0) is 0. And in the neighborhood of this there are other extremals or any curve y, admissible curve y, which joins the points A and B, we see that delta I (y) is greater than 0, if W is greater than equal to 0.

And so, we have minimum or let us write it, if W is greater than 0 for any value of y prime, then we get strong minimum, because here, since y this is does not depend on y

prime. So, we have zero order proximity, and if if this delta, if delta $I(y)$ will... If W is greater than 0 for y prime close to p then we get weak minimum.

(Refer Slide Time: 21:12)

Similarly, (no audio from 21:10 to 21:17) If W is less than equal to 0 for any value of y prime, we have strong maximum, since in this case delta $I(y)$ will be negative for arbitrary values of y prime. If W is less than equal to 0 for y prime close to p , then

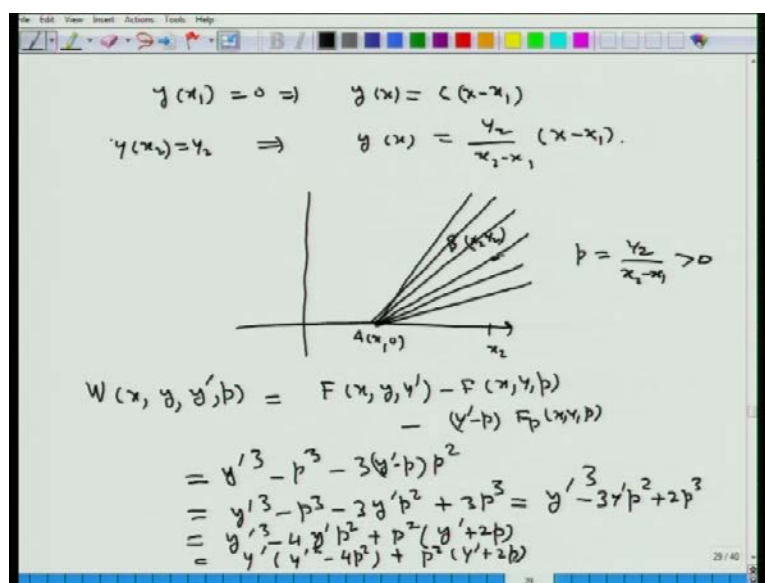

(No audio from 22:16 to 22:28)

Then we get weak maximum. So, that is what we had considered last time through various examples. And so here, we have to just check, whether this W is positive or negative in the neighborhood of our extremal, which we want to test. So, will consider some examples here.

(No audio from 22:56 to 23:05)

So, let us call this 19.2, $I(y)$ equal to x_1 to x_2 y prime cube dx here, y of x_1 equal to 0, $y(x_2)$ equal to y_2 . We assume that this y_2 is greater than 0, and this x_1 is less than x_2 . So, here since this F , which is y prime cube is independent of x and y , the extremals are straight lines, say, y equal to αx plus β .

(Refer Slide Time: 24:17)

Now, y at x_1 equal 0 implies that $y(x)$ equal to some constant times x minus x_1 , and y at x_2 equal to y_2 , which is positive. So, this will imply that c must be equal to y_2 over x_2 minus x_1 ; and so, we get these extremals like this. So, these are depicted here. So, this is a point A , which is $(x_1, 0)$ and these are the straight lines. So, this extremal here this is x_2 here, and this is x_2 to y_2 , and the slope of this p here, which is y' on this. So, this is B here, this is B like this.

So, p is y_2 over x_2 minus x_1 , which is positive by our assumption that y_2 is positive and x_2 is greater than x_1 . So, there are other extremals going like this in the neighborhood of this.

(No audio from 25:42 to 25:49)

And so, we check that $W(x, y, y', p)$ which is $F(x, y, y') - F(x, y, p) - (y' - p) F_p(x, y, p)$. So, this in this case will be y'^3 minus, now y' we have to substitute p here on the extremal.

So, p^3 minus this y' minus p into F_p means $3p^2$. So, this is equal to y'^3 minus p^3 minus $3y'p^2$ plus $3p^3$. So, that is equal to y'^3 minus $3y'p^2$ plus $2p^3$ here, we can see that, we can write it as y'^3 minus $4y'p^2$ plus $p^2(y' + 2p)$ taking common in this. So, you get $y' + 2p$.

And then, here we take, this as y' , here we taking y' common. So, you get y' equal to y' minus y'^2 minus $4p$ square plus p square into y' plus $2p$.

(Refer Slide Time: 27:58)

$$\begin{aligned}
 &= y'(y'+2p)(y'-2p) - p^2(y'+2p) \\
 &= (y'+2p)(y'^2 - 2py' + p^2) \\
 &= (y'+2p)(y'-p)^2.
 \end{aligned}$$

Since $p > 0$ and y' is close to p , then we have $y' > 0$.

If we take $y' \in (\frac{p}{2}, \frac{3p}{2})$, $y' > 0$.

So $W > 0$. Hence we have weak minimum.

And so, factorizing the second factor y' plus y' plus $2p$ into y' minus $2p$ minus p square y' plus $2p$. So, this finally, gives us y' plus $2p$ into y' minus y' square minus $2p y'$ y' square minus $2p y'$ plus p square, that is y' plus $2p$ into y' minus p square. So, we can see that since this is nonnegative.

And so, since p is positive here, and if y' is close to p , then we have y' positive, such like this you have 0 here, and p is here and supposing we take this small level around this. So, that y' lies in this. So, than y' will be positive here.

So, we can see that, that is, if we take, if we take y' lying in the interval p by 2 to $3p$ by 2 . So, then we see that than y' will be positive. So, if y' is close to p like this. So, that it does not this neighborhood does not take this 0 inside, we see that y' will be positive. And so, this W will be positive here, hence we have weak minimum.

Since, here the sign of W depends on y' . So, it is actually in the first order proximity, because y' will have to be close to p that means, derivatives will have to

be... Derivatives of these nearby functions should be close enough. So, that is the first order proximity, which was defined earlier.

(Refer Slide Time: 30:55)

Example 19.3

$$I(y) = \int_{x_1}^{x_2} [6y'^2 - y'^4 + yy'] dx,$$

$$y(x_1) = 0, \quad y(x_2) = y_2 > 0, \quad x_1 < x_2.$$

$$F = 6y'^2 - y'^4 + yy'$$

Euler's Eqn

$$F_y - \frac{d}{dx} F_{y'} = 0 \Rightarrow y' - \frac{d}{dx} [12y' - 4y'^3 + y] = 0$$

$$\Rightarrow y'' - 12y'' + 12y'^2y'' - y'' = 0$$

$$-12y''(1 - y'^2) = 0$$

$$\Rightarrow y'' = 0 \quad \text{or} \quad y' = \pm 1.$$

$$\Rightarrow y = \alpha x + \beta \quad \text{or} \quad y = \pm x + \gamma.$$

Now, the next example.

(No audio from 30:52 to 31:01)

This is 19.3 will write. So, here $I(y)$ is integral x_1 to x_2 $6y'$ prime square minus y' prime to the power 4 plus $y y'$ prime dx . And the conditions are y of x_1 equal to 0, and y of x_2 to equal to y_2 again we assumed that this is positive and this x_2 is greater than x_1 , so, x_1 less than x_2 . And so here F is $6y'$ prime square minus y' prime power 4 plus $y y'$ prime.

And the extremals are solutions of this F_y minus d by dx of $F_{y'}$ prime equal to 0 implies that is Euler's equation.

(No audio from 32:14 to 32:21)

So, it gives us, F_y gives us y' prime here and minus d by dx of $F_{y'}$ prime means $12y'$ prime minus $4y'$ prime cube plus y equal to 0.

So, we get y' prime minus $12y'$ double prime plus $12y'$ prime square y' double prime minus y' prime equal to 0. So, we get this cancels here, and so, minus. So, it is should have been F_y minus $6y'$ prime and this... So, we take minus $12y'$ out, y' double prime out. So, we get this minus $12y'$ double prime into 1 minus y' prime square equal to 0. So,

this implies that either $y'' = 0$ or $y' = \pm 1$, and integrating it again, we get $y = \alpha x + \beta$ or $y = \pm x + \gamma$. So, we get straight lines as extremals.

(Refer slide Time: 34:15)

$$\begin{aligned}
 y(x_1) = 0 &\Rightarrow y(x) = C(x - x_1) \\
 y(x_2) = y_2 &\Rightarrow y(x) = \frac{y_2}{x_2 - x_1}(x - x_1) \\
 p &= \frac{y_2}{x_2 - x_1} > 0.
 \end{aligned}$$

$$\begin{aligned}
 W(x, y, y', p) &= F(x, y, y') - F(x, y, p) - (y' - p) F_p(x, y, p) \\
 &= 6y'^2 - y'^4 + yy' - (6p^2 - p^4 + yp) - (y' - p)(12p - 4p^3 + yp) \\
 &= -(y' - p)^2 [y'^2 + 2py' - (6 - 3p^2)] \\
 E(y', p) &= y'^2 + 2py' - (6 - 3p^2)
 \end{aligned}$$

$W > 0$	y	$E < 0$
$W < 0$	y	$E > 0$

And y at x_1 equal to 0 would imply that y of x must be some C constant times x minus x_1 , and y at x_2 equal to y_2 this implies that $y(x)$ equal to y_2 over x_2 minus x_1 to x minus x_1 as we have got earlier. And so here so on this extremal p is y_2 over x_2 minus x_1 , which is positive. Now, we look at this sign of this x, y, y', p that is the Weierstrass Function, which is defined as F of x, y, y' minus F of x, y, p minus y' minus p times F_p of x, y, p .

And so, in this case, we get equal to $6y'^2$ minus y'^4 plus yy' , that is F here $F(x, y, y')$, and then same thing at y' replaced by p . So, we get minus $6p^2$ minus p^4 plus yp , and then minus y' minus p and F differentiated partially with respect to p , here when y' is replaced by p . So, we get $12p$ minus $4p^3$ plus yp .

So, this can be simplified finally, as minus y' minus p whole square times y' square plus $2p$ y' minus 6 minus $3p^2$. So, if we denote this expression in the bracket as E , which is function of y' p only, and so that is y' square plus $2p$ y' minus 6 minus $3p^2$.

And so, we have to check this, so, if W will be positive, if E is negative and W will be negative, if E is positive. So, we have to see that if E is negative, then W is positive in this case, we will have either strong minimum or weak minimum in the first case. And in the second case, we will have strong maximum or weak maximum depending upon, whether it is dependent on y prime or not.

(Refer Slide Time: 37:33)

Handwritten notes on a digital whiteboard:

$$E = 0 \Rightarrow y'^2 + 2py' - (6-3p^2) = 0$$

$$\Rightarrow y' = -p \pm \sqrt{p^2 + (6-3p^2)}$$

$$= -p \pm \sqrt{6-2p^2}$$

If $6-2p^2 < 0$ then we get complex roots. Hence E will not vanish for any real value of y' .

$E > 0$ for large y' . Hence if $6-2p^2 < 0$ (i.e., $p > \sqrt{3}$) $E > 0$ for all y' .

$\Rightarrow W < 0$ for all values of y' so we get strong maximum for $p > \sqrt{3}$.

When $p=1$ and $y'=1$ we see that

$$E = 1 + 2 - (6-3) = 0$$

And for $p > 1$ and y' close to p .

So, we just check the sign of E . So, E equal to 0 implies that this y prime square plus $2p$ y prime minus 6 minus $3p$ square equal to 0. So, the roots of this equation are y prime equal to minus p plus minus square root p square plus 6 minus $3p$ square, that is minus p plus minus root 6 minus $2p$ square.

So, we check the various cases, when 6 minus $2p$ square is positive, when it is 0 and when it is negative. So, first case when if 6 minus $2p$ square is less than 0, then we get complex roots.

Hence, E will not vanish on this line. So, here we have like this p and this is E here. So, on the p axis, here E will not vanish on the... So, there is no point here on p axis, where E will be 0, will not vanish for any real p . So, we can remove this thing. So, here and this E is positive for large y prime.

(No audio from 39:50 to 39:57)

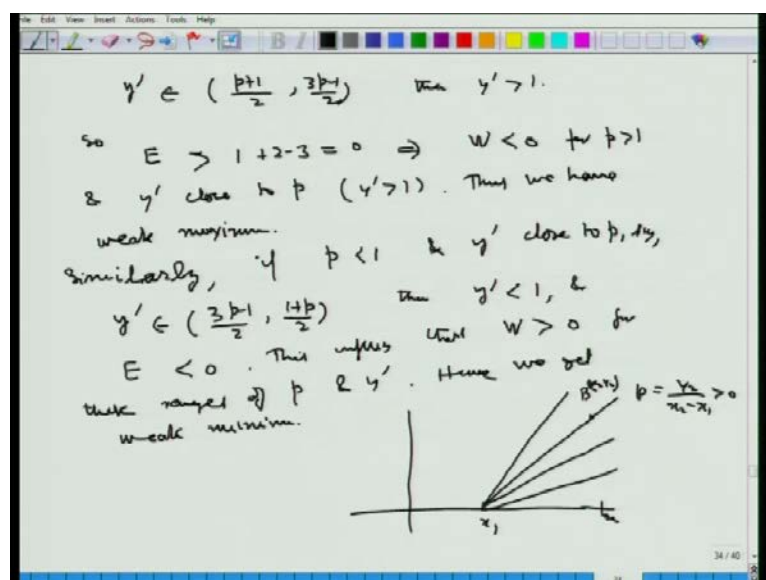

Any real value of **any for real value of** y' , for large y' is **is** positive, because you can see that y' is the dominating term here. And so, if y' is **...** y' square is the dominating term here, and if y' is large, y' square will decide the sign of E .

And so, for large values of y' E will be positive. Hence, if p is that means, $6 - 2p^2$ negative that is p greater than $\sqrt{3}$ here, p will be positive, for all y' . And so, this will imply that W is negative for all **y' prime** values of y' . So, we get strong maximum for p greater than $\sqrt{3}$. So, that is the first case, and when **...**

(No audio from 41:33 to 41:41)

So, here we see that, if p is **and p is** 1 and y' is also 1, we see that E equal to 1 plus 2. So, we substitute p and y' equal to 1 minus 6 minus 3. So that is 0, so and for p greater than 1 and y' close to p .

(Refer Slide Time: 42:33).

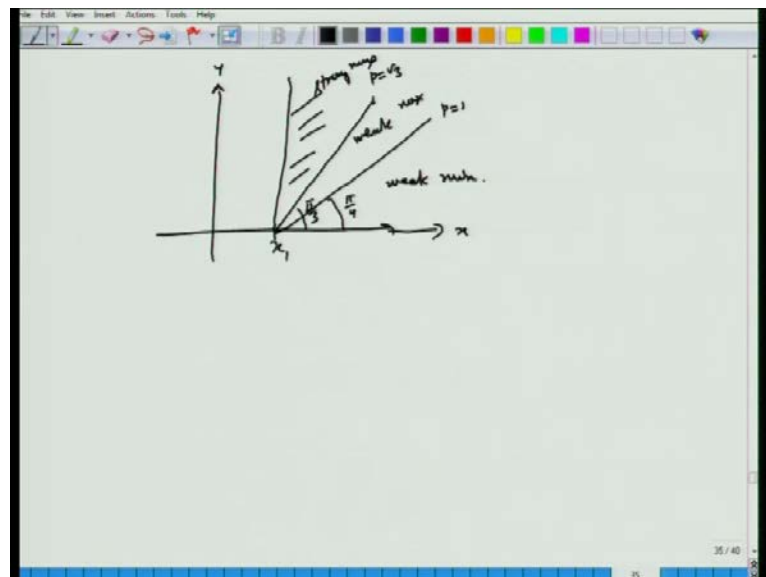

We take this intervals that y' is in $p + 1/2$ to $3p - 1/2$, then y' will be greater than 1. And so, E will be greater than **E will be greater than** 1 plus 2 minus 3 and that is equal to 0. And this will imply that W is less than 0 for p greater than 1, and y' close to p that means, y' **y' prime** also greater than 1. Thus, we have weak maximum here.

Similarly, **similarly**, if p is less than 1 and y' close to p , say, y' lying in the interval $3p - 1$ by 2 to $1 + p$ by 2 , then y' will be less than 1, and then E will be negative. And this implies that W is positive for these ranges of p and y' (**((**)). Hence, we get weak minimum.

So, here we have the following picture that we have here x_1 , and then here we have x_2 , and these are the extremals going here. And let say, this is the point here lying on this extremal p , which is (x_2, y_2) having p equal to y_2 over $x_2 - x_1$ positive, and here we see that if in this range, if p is greater than 1.

(Refer Slide Time: 45:29)

So, that is we have this situation that p is by 3, and then we have p is by 4. So, this corresponds to p equal to root 3, this corresponds p equal to 1, and so here and p is greater than, the slope is greater than root 3. So, here **here** we get strong maximum, here we get weak maximum, and here we get weak minimum in this range. So, that is x and y axis here and this is the point x_1 . So, in this case, we have seen that the depending upon, what are the slope p , and in the neighborhood of this if y' has **close value** close to p then we can decide that the functional, whether it will have strong maximum or weak maximum or weak minimum, within those ranges of p and y' .

Next, in the next lecture, we will be considering various cases of these functional and we will see, we will get other condition, which is known as Lysander condition, which is similar to check. Here, finding that W is positive or negative is a difficult, if we straight

away apply the definition of W , you see that we will $(())$ use the Taylor series expansion of W . And we will be able to get a nice condition, easy to verify, which is known as Lysander condition that we will consider in next lecture. Thank you very much.
