Lecture No. # 20

Welcome viewers to the NPTEL lecture series on the Calculus of variations, this is the last lecture 20 th lecture of the series. Recall that in the last lecture, we discuss sufficient conditions, Jacobi's condition, and Lysander, and Weierstrass function, where we showed that if Jacobi's condition is satisfied, and if Weierstrass function has a positive sign or negative sign throughout in a certain interval, then we get a minimum strong minimum or weak minimum depending upon, whether y prime is arbitrary or y prime is to be assumed to close to p.

(Refer Slide Time: 01:10)

The image shows a digital whiteboard with handwritten mathematical notes. At the top, the functional is given as $I(y) = \int_{x_1}^{x_2} F(x, y, y') dx$. Below this, it states that $A(x_1, y_1)$ and $B(x_2, y_2)$ are given fixed points, with $y_1 = y(x_1)$ and $y_2 = y(x_2)$. The notes then discuss Jacobi's condition, stating that the function u of the equation $(F_{yy} - \frac{d}{dx} F_{yy'}) u - \frac{d}{dx} (F_{yy'} u') = 0$ vanishes only at $A(x_1, y_1)$ on the interval $[x_1, x_2]$ and thus we have the existence of a conjugate field at $A(x_1, y_1)$ containing the point $B(x_2, y_2)$.

$$I(y) = \int_{x_1}^{x_2} F(x, y, y') dx$$

$A(x_1, y_1)$ & $B(x_2, y_2)$ are given fixed points, $y_1 = y(x_1)$ & $y_2 = y(x_2)$.

Jacobi's condition: The function u of the equation

$$(F_{yy} - \frac{d}{dx} F_{yy'}) u - \frac{d}{dx} (F_{yy'} u') = 0$$

vanishes only at $A(x_1, y_1)$ on the interval $[x_1, x_2]$ and thus we have the existence of a conjugate field at $A(x_1, y_1)$ containing the point $B(x_2, y_2)$.

So, recall that we had the functional. So, recall that we have the functional $I(y)$ equal to integral x_1 to x_2 F of (x, y, y') dx , where the boundary points are given $A(x_1, y_1)$ and $B(x_2, y_2)$ are given fixed points, here y_1 equal to y at x_1 , and y_2 equal to y at x_2 .

So, the Jacobi condition, that is the function u of the **function u of the** equation $(F_y y' - y' F_{y'} - F_p) u' = 0$ vanishes only at A that is (x_1, y_1) on the interval x_1, x_2 ; and this we have the existence of a central field at $A(x_1, y_1)$ containing the point $B(x_2, y_2)$. So, that is the Jacobi condition

(Refer Slide Time: 03:51)

then we need to check the sign of the Weierstrass function

$$W(x, y, y', p) = F(x, y, y') - F(x, y, p) - (y' - p) F_p(x, y, p)$$

here $y' = p$ on the extremal $y = y(x, c_0)$ passing through the points $A(x_1, y_1)$ and $B(x_2, y_2)$. Here $y = y(x, c)$ forms the central field of extremals at the center $A(x_1, y_1)$.

$$\Delta I(y) = \int_{x_1}^{x_2} W(x, y, y', p) dx.$$

Hence $\Delta I(y) \geq 0$ if $W \geq 0$, $\Delta I(y) \leq 0$ if $W \leq 0$, and $W = 0$ on $y = y(x, c_0)$.

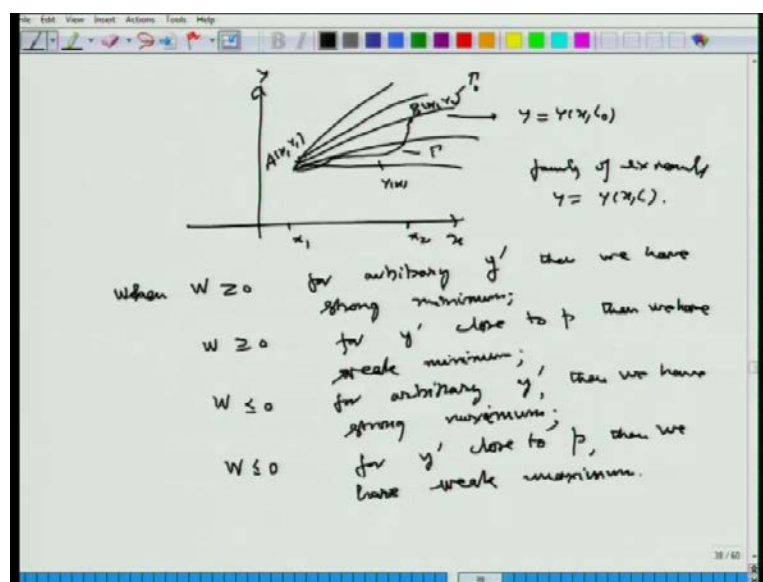

And then **then** we need to check the sign of the Weierstrass function; that is W , which is function of (x, y, y', p) equal to $F(x, y, y') - F(x, y, p) - (y' - p) F_p(x, y, p)$; here $y' = p$ on the extremal $y = y(x, c_0)$ passing through the points $A(x_1, y_1)$ that the central centre of the central field and $B(x_2, y_2)$.

So, here we have the extremal $y = y(x, c_0)$ which is a fixed, c_0 is fixed value of the parameters c , here $y(x, c)$ forms the family, here $y = y(x, c)$ forms the central field of extremals at the centre and for this $c = c_0$, we are on this extremal, which passes through the given points $A(x_1, y_1)$ and $B(x_2, y_2)$. So, we want to check whether this extremal, which is $y(x, c_0)$ minimizes or maximizes the given functional I .

So, here we need to check that since, here we have seen that this $\Delta I(y)$ as $\Delta I(y)$ is integral $\int_{x_1}^{x_2} W(x, y, y', p) dx$. So, we see that; this $\Delta I(y)$ will be greater than equal to 0; if W is greater than equal to 0. And similarly $\Delta I(y)$ be less than equal to 0; if W is less than equal to 0; and $W = 0$ on $y = y(x, c_0)$, because here this $y' = p$. So these two terms are canceled,

and y' equal to p here, this factor will be 0. So, W equal to 0, so $\delta I(y)$ equal to 0. If we are taking y equal to this is general y here, then any here this y is any curve joining these two points.

(Refer Slide Time: 07:59)

So, here situation is like this. We have central field here at A like this. So, this is A (x_1 , y_1) and B is there on this (x_2 , y_2). So, this is the curve is the extremal y equal to $y(x, c_0)$ and this is the family of extremals given by $y(x, c)$. So, a family of extremals y equal to $y(x, c)$.

So, here c equal to c_0 , we have this extremal, which passes through these given points. So, we want to see, whether this extremal is minimizing or maximizing at the given functional I ; and this any y here is, this is general $y(x)$, which this we had denoted as γ_0 , and this we had denoted as general γ . And so that is what we have here this on Lysander γ , joining these two points A and B.

So, this is x_1 here and this point is x_2 here. So, we had seen that in various examples; that we calculated W and we see that, when W is **when W is** greater than equal to 0 for arbitrary y' , then we have strong minimum. And if W is greater than equal to 0 for y' close to p , then we have weak minimum; and if W is less than equal to 0 for arbitrary y' , and we have strong maximum, and if W is less than equal to 0 for y' close to p , then we have weak maximum.

Since, if we have to consider y' close to p ; that means, we are considering that this in the first order proximity, if y' is arbitrary, then we are considering the 0 order proximity. So, as defined earlier, we get in case y' is arbitrary, we get a strong minimum or maximum depending upon the sign of W . And in case when y' is **is** to be assumed to be close to p , then we get a weak minimum or maximum depending upon the sign of W .

And here checking the sign of in various examples, we had considered here like in this case, we saw that this W expression comes out to be quite complicated, and checking the sign of this is not that easy. So, we look for a simple condition, which would guarantee as the same thing, but has been concluded earlier like this.

(Refer Slide Time: 12:13)

By Taylor's Theorem,

$$W = F(x, y, y') - F(x, y, p) - (y' - p) F_p(x, y, p)$$

$$= F_{yy'}(x, y, \tilde{p}) \frac{(y' - p)^2}{2!},$$

where $\tilde{p} = p + \theta(y' - p)$, $0 < \theta < 1$,

$$\text{sgn}(W) = \text{sgn}(F_{yy'}(x, y, \tilde{p})).$$

Hence, if $F_{yy'} > 0$ for arbitrary y' , then $W > 0$ for arbitrary y' , hence we get strong minimum.

q) $F_{yy'} > 0$ for y' close to p then $W > 0$ for y' close to p hence we get weak minimum.

So, we just see that; if we use Taylor expansion here. So, W is $F(x, y, y')$ minus $F(x, y, p)$ minus $(y' - p) F_p(x, y, p)$; if we expand assuming that y' is close to p , then by Taylor theorem. **By Taylor theorem** Taylor's theorem, this can be expanded like this. So, you will have F here, this $F_{yy'}$ double prime **prime** into $(y' - p)$, because here we expand this in the neighborhood of p .

So, this term will cancel; and that first derivative term will cancel here like this; and so, we will be having thus y' double prime, **double prime** this is to be evaluated at some intermediate point like this is (x, y, \tilde{p}) into $(y' - p)$ whole square upon

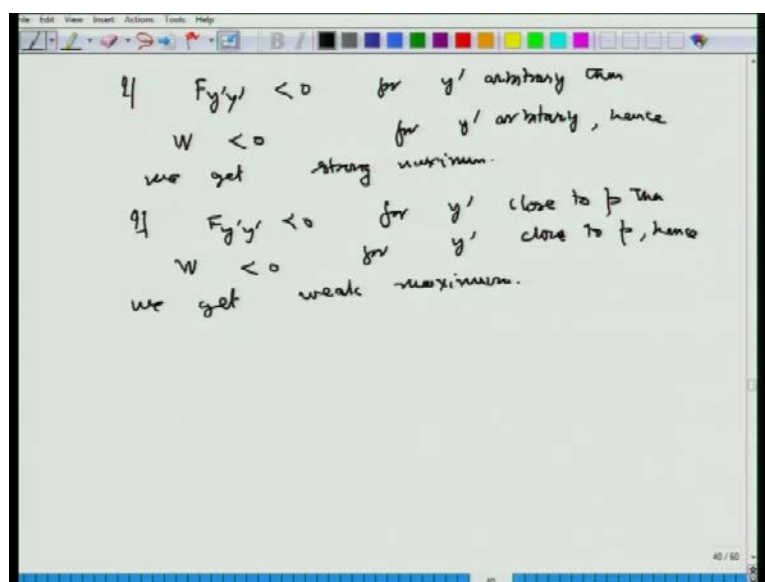

factor two, where p tilde is p plus some θ times y' minus p , where $0 < \theta < 1$.

So, we see that the sign of W will then, if y' is close to that p ; and we see that the sign of this can be determined by the sign of $y' - p$. So, here this is since, this $(y' - p)^2$ on factor 2 is positive. So, this sign of W , then is sign of $F(y', p)$ here.

So, we see that in the neighborhood of this p y' will be close to p , in case this factor is small. Here, we see that the sign of W , if it can be seen that if sign of W is sign of a prime y' for arbitrary y' , then again we get here that is same thing to be determined by whether the this sign of that this is plus 1 or minus 1.

So, like that we will see that; hence $F(y', p)$ positive for arbitrary y' , then this W is greater than 0 for arbitrary y' , hence we get strong minimum. If here if this... So, if $F(y', p)$ greater than 0 for y' close to p , then W is greater than 0 for y' close to p , hence we get weak minimum.

(Refer Slide Time: 16:37)

And if $F(y', p)$ is negative for y' arbitrary, then W will be less than 0 for y' arbitrary, hence we get strong maximum. And if this $F(y', p)$ is negative for y' close to p , then W is negative for y' close to p , hence we get

weak maximum. So, that is what we have to check here; that F_y prime y prime is whether positive or negative, which is easier to check compared to the sign of W .

(Refer Slide Time: 18:08)

Example 20.1

$$I(y) = \int_{x_1}^{x_2} (y'^2 - y^2) dx$$

$$y(x_1) = 0, \quad y(x_2) = 0, \quad x_1 < x_2.$$

$$F = y'^2 - y^2$$

Euler's equation $F_y - \frac{d}{dx} F_{y'} = 0 \Rightarrow$

$$-2y - \frac{d}{dx} (2y') = 0$$

$$\Rightarrow y'' + y = 0$$

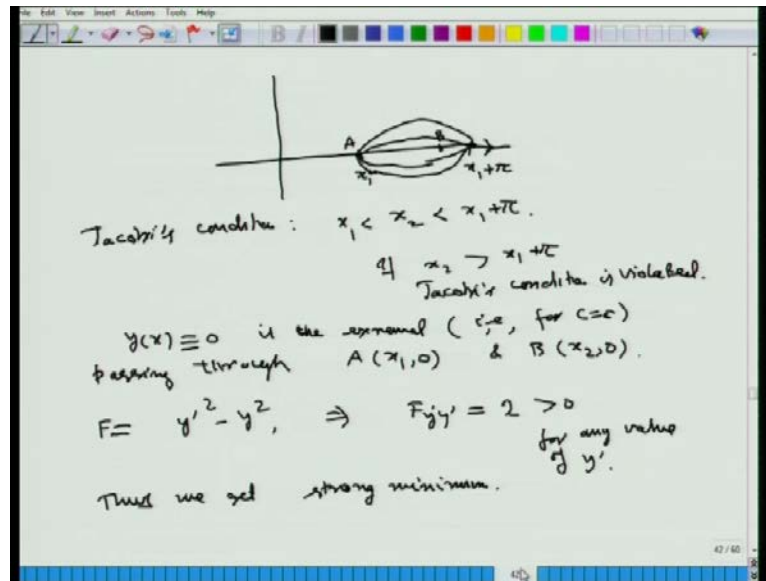

$$\Rightarrow y(x) = \alpha \cos x + \beta \sin x$$

$$y(x_1) = 0 \Rightarrow y(x) = C \sin(x - x_1).$$

So that is, what we will do in this example. So, let us say, this is 20.1. Here, we have $I(y)$ equal to integral x_1 to x_2 (y prime square minus y square) dx and y at x_1 equal to 0 and y at x_2 equal to 0.

Here, we have this x_1 less than x_2 ; obviously, and so, here F is y prime square minus y square; and Euler's equation F_y minus d by dx $F_{y'}$ equal to 0 implies that minus $2y$ minus d by dx of $2y'$ equal to 0, this implies that y double prime plus y equal to 0; and so, solving this, we get $y(x)$ equal to $\alpha \cos x$ plus $\beta \sin x$; and y condition y at x_1 equal to 0 implies that $y(x)$ equal to some constant $c \sin x$ minus x_1 , this has already been done. So, that is what we get here.

(Refer Slide Time: 20:05)

So, we have this x_1 is somewhere here and we have $x_1 + \pi$. So, we get these curves here like this. And we know that the Jacobi condition is that this x_2 must be... So, Jacobi condition **Jacobi's condition** would be fulfilled, if this x_2 which is greater than x_1 , it should be less than $x_1 + \pi$, if x_2 is greater than **if x_2 is greater than** $x_1 + \pi$, Jacobi's condition is violated.

So, we need to have this x_2 here, this point and clearly this $y(x)$ identically 0 is the extremal that is, for c equal to 0, we have this extremal y identically 0; passing through A that is $(x_1, 0)$ and B that is $(x_2, 0)$. So, this is the extremal here, y identically 0 to this x axis part of this axis, which is passing through these two points is A ; and this point is B here, on the x axis.

Now, we need to check whether on this extremal, we have maximum value of I or minimum value of I . So, for that we had checked it earlier, by the sign of W . Now, we check, we have to calculate this F , here F is y' prime square minus y square. So, this implies that $F_{y'} = 2$, which is positive for any value of y' . Thus, we get strong minimum in this case.

So, this $I(y)$ here will be having minimum value, strong minimum value on the extremal y identically 0, which h is actually 0 here.

(Refer Slide Time: 23:33)

Example 20.2 (Brachistochrone)

$$I(y) = \int_{x_1}^{x_2} \frac{\sqrt{1+y'^2}}{\sqrt{y}} dx$$

$$y(x_1) = 0, \quad y(x_2) = y_2 > 0.$$

Extremals are cycloids:

$$\left. \begin{aligned} x &= \alpha(t - \sin t) + \beta \\ y &= \alpha(1 - \cos t) \end{aligned} \right\}$$

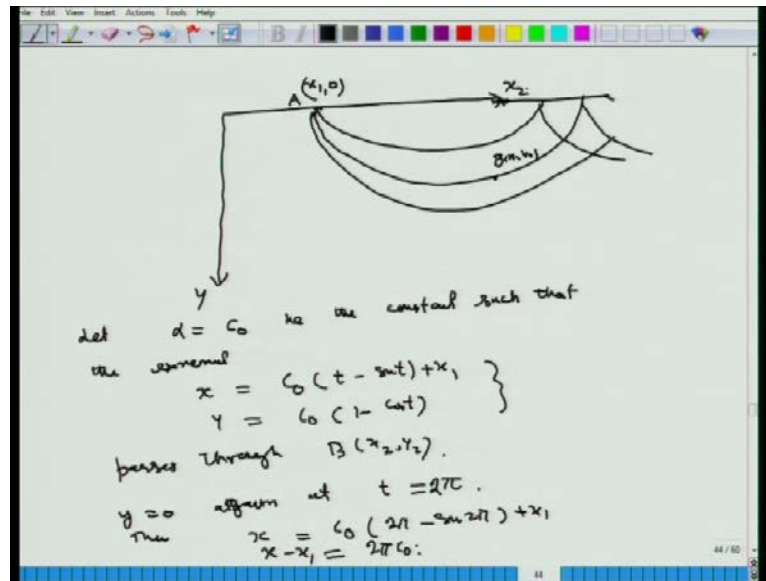

$t=0$, we are at $A(x_1, y_1) = (x_1, 0)$.

$$\left. \begin{aligned} x &= \alpha(t - \sin t) + x_1 \\ y &= \alpha(1 - \cos t) \end{aligned} \right\} \begin{array}{l} \text{one parameter} \\ \text{family of} \\ \text{extremals} \\ \text{forming a central} \\ \text{field at } A \end{array}$$

And so, now, next we will consider the example of Brachistochrone that is 20.2. So, this is Brachistochrone, which is come in our discussions at several points, here $I(y)$ is x_1 to x_2 $\frac{\sqrt{1+y'^2}}{\sqrt{y}} dx$; and we take y at x_1 equal to 0, and y at x_2 equal to y_2 , this is strictly positive here. And we know that; the extremals are cycloids given by x equal to $\alpha(t - \sin t) + \beta$; and y equal to $\alpha(1 - \cos t)$; and here this at t equal to 0. So, t equal to 0, we have y at x_1 .

So, we are at **at** t equal to 0; we are at **we are at** A that is (x_1, y_1) which is actually equal to $(x_1, 0)$; and so, it is plus that x must be equal to $\alpha(t - \sin t) + x_1$ and y equal to $\alpha(1 - \cos t)$. So, this is the one parameter family of extremals, one parameter family of extremals forming central field at A , which is $(x_1, 0)$.

(Refer Slide Time: 26:07)

So, that is the picture here we have. So positive y will take like this and this is positive x and this is the point x_1 here, and we have the cycloids going like this, and here they then go like this, and so, here we need to see that. So, this is the family of this is the central field at this is the point A , and we need to see that B is somewhere here. So, this is x_2 here. So, B is (x_2, y_2) , A is $(x_1, 0)$ like this.

So, we see that here, let us say, let this α equal to c_0 be constant, such that the extremal here, x equal to c_0 to $(t - \sin t)$ plus x_1 and y equal to $c_0(1 - \cos t)$ passes through the point B which is (x_2, y_2) . So, we see that this c_0 should be such that it is not going to be this that extremal, where I mean, this is B point should be before where these extremals start intersecting each other.

So that means, we see that this y will be 0. So, y will be 0, y equal to 0 again at t equal to π ; and so, we see that, because here we substitute t equal to 2π , then this becomes 0. And so, y equal to 0 and t equal to of course, when t equal to 0 here we are at A , so there y equal to 0. So, y will be 0 again at t equal to 2π and so, then x will be equal to so, at 2π this so, c_0 ; t equal to $(2\pi - \sin 2\pi)$ plus x_1 . So, this is will be... So, $x - x_1$ must be equal to $2\pi c_0$.

(Refer Slide Time: 29:20)

For $x = 2\pi c_0 + x_1$, we get $y = 0$ again.
Hence $x_1 < x_2 < x_1 + 2\pi c_0$.
Then the Jacobi condition will be satisfied.
 $F_{y'y'} = \frac{1}{\sqrt{y} (1+y'^2)^{3/2}} > 0$ for any y' .
Hence we get strong minimum.
Example 20.3 $I(y) = \int_{x_1}^{x_2} y^3 dx$
 $y(x_1) = 0$, $y(x_2) = y_2 > 0$, $x_1 < x_2$.
 $y = \frac{y_2}{x_2 - x_1} (x - x_1)$, $p = \frac{y_2}{x_2 - x_1} > 0$.
 $F_{y'y'} = 6y' > 0$ if y' is close to p , i.e. $y' > 0$.
Weak minimum.

So that means, here x equal to, so x_2 must be. So, we have this x minus... So, x equal to $2\pi c_0 + x_1$; that is where we will get the value of y . So, for this, we get y equal to 0 again; hence, this x_2 must be less than. So, this x_1 less than x_2 must be less than $x_1 + 2\pi c_0$. So, this is the Jacobi condition. Then the Jacobi condition will be satisfied. Thus we see that here, in this case, we have x_2 must be like this that $x_1 + 2\pi c_0$.

Now, we check in this case $F_{y'y'}$ $F_{y'y'}$ actually comes out to be in this case $\frac{1}{\sqrt{y} (1+y'^2)^{3/2}}$, which is always greater than 0 for any y' , hence we get strong minimum in this case. In the last example here, which we have several times visited earlier, x_1 to x_2 y prime cube dx and we see that here y at x_1 equal to 0, and y at x_2 equal to y_2 , which is positive here x_1 is less than x_2 .

And we see that here, this extremals are y_2 over x_2 minus x_1 times x minus x_1 . So, here we see that; p is y_2 over x_2 minus x_1 , which is positive. And here, $F_{y'y'}$ comes out to be $6y'$, which will be positive, if y' is close to p ; that is y' is positive; and so, we get weak minimum in this case. And we cannot conclude more than this thing here, we **we** had earlier by directly seeing the sign of W we could say something more than this of course.

(Refer Slide Time: 32:41)

The image shows a handwritten derivation on a digital whiteboard. The equations are as follows:

$$\Delta I(y) = \int_{x_1}^{x_2} F(x, y + \delta y, y' + \delta y') dx - \int_{x_1}^{x_2} F(x, y, y') dx$$

$$= \int_{x_1}^{x_2} (F_y \delta y + F_{y'} \delta y') dx + \int_{x_1}^{x_2} [F_{yy} \delta y^2 + 2F_{yy'} \delta y \delta y' + F_{y'y'} \delta y'^2] dx + R$$

Below the second equation, there is a note: "R involves all higher powers of δy & $\delta y'$ more than two."

$$\Delta I(y) = \delta I(y) + \delta^2 I(y) + R$$

Below this, it says: "Necessary condition that $\delta I(y) = 0 \Rightarrow$ "

$$\Delta I(y) = \delta^2 I(y) + R$$

Now, let us see that; how we actually get these conditions in some other way, here let say that this delta I (y) this is x_1 to x_2 integral F of x, y, y' d x y is change to y plus delta y , and y' plus delta y' minus x_1 to x_2 F (x, y, y') d x .

And here this can be written at this x_1 to x_2 expanding it by Taylor series, we get $F_y \delta y$ plus $F_{y'} \delta y'$ d x plus we get x_1 to x_2 $F_{yy} \delta y^2$ plus $2 F_{yy'} \delta y \delta y'$ plus $F_{y'y'} \delta y'^2$ plus R. Which involves, R involves only higher powers of delta y and delta y' more than 2.

So here, so that therefore, this $\delta I(y)$ is delta the first variation here, and plus this delta is square $I(y)$ plus R. So, this the first variation, and this the second variation, which is the second term here plus R, and the necessary condition **condition** that delta $I(y)$ must be 0 and implies that delta I delta $I(y)$ then finally, is equal to delta square $I(y)$ plus R.

(Refer Slide Time: 35:07)

Sign of $\Delta I(y)$ is decided by $\Delta^2 I(y)$ for small variations δy & $\delta y'$.

We note that

$$\int_{x_1}^{x_2} d(w(x) \delta y^2) = \int_{x_1}^{x_2} [w'(x) \delta y^2 + 2w(x) \delta y \delta y'] dx$$

$$= w(x) \delta y^2 \Big|_{x_1}^{x_2} = 0 \quad \delta y(x_1) = \delta y(x_2) = 0$$

$$\Delta I(y) = \int_{x_1}^{x_2} \left[(F_{yy} + w') \delta y^2 + 2(F_{yy'} + w) \delta y \delta y' + F_{y'y'} \delta y'^2 \right] dx$$

$$= \int_{x_1}^{x_2} F_{y'y'} \left[\left(\frac{F_{yy} + w'}{F_{y'y'}} \right) \delta y^2 + 2 \left(\frac{F_{yy'} + w}{F_{y'y'}} \right) \delta y \delta y' + \delta y'^2 \right] dx$$

So, this sign of the sign of delta I (y) is decided by delta square I (y) for small variations delta y and delta y prime. So, we see that we need to check only this sign of this. So, what we do here, we check we note that this, integral x 1 to x 2 this d of some function let say, w (x) of into delta y square is actually, x 1 to x 2 w prime (x) delta y square plus 2 w (x) delta y **delta y** prime delta y dx, but on the other side this thing is w (x) delta y square evaluated at x 1 to x 2 and this is 0, because delta y is delta y at x 1 as well as delta y at x 2 is 0.

And so, this term, we can add to this. So, we have delta I (y) equal to integral x 1 to x 2, we add these things here, we get here F w prime x. So, F y the second variation here, we will add in this, we get F y y plus W prime delta y square plus 2 (F y y prime w) delta y prime delta y plus F y prime y prime delta y prime square d x. And we take this x 1 to x 2, this F y prime y prime we take out; and we see that here, we get F y y plus w prime over F y prime y prime delta y square plus 2 F y y prime plus W over F y prime y prime delta y prime delta y plus delta y prime square dx.

So, we want to make this perfect square. So, we select this gabbling, such a way that this is perfect square, so that means the square of this must be this into this. So, there is one here.

(Refer Slide Time: 38:29)

$$\left(\frac{F_{yy'} + w}{F_{y'y'}} \right)^2 = \frac{F_{yy} + w'}{F_{y'y'}}.$$

$$\frac{F_{yy'} + w}{F_{y'y'}} = - \frac{u'}{u}$$

$$w = - F_{yy'} - F_{y'y'} \frac{u'}{u}.$$

$$w' = - \frac{d}{dx}(F_{yy'}) - \frac{d}{dx}(F_{y'y'}) \frac{u'}{u} - F_{y'y'} \left(\frac{u'' - u'^2}{u^2} \right)$$

$$F_{yy} + w' = F_{yy} - \frac{d}{dx}(F_{yy'}) - \frac{d}{dx}(F_{y'y'}) \frac{u'}{u} - F_{y'y'} \left(\frac{u'' - u'^2}{u^2} \right)$$

$$= - F_{y'y'} \frac{u'}{u}.$$

$$(F_{yy} - \frac{d}{dx} F_{yy'}) u - \frac{d}{dx} (F_{y'y'} u') = 0 \quad \text{Jacobi eqn.}$$

So that means, we have $(F_{yy} + w) / (F_{y'y'})$, this must be square of this must be equal to $(F_{yy} + w') / (F_{y'y'})$. So, that is, how we have to check, we have to select this w , in such a way so; that means, we take this substitutions $y = F_{yy} + w$ over $F_{y'y'}$ equal to minus u' over u , we substitute it like this, and so, here w must be selected like this that it should be minus F_{yy} minus $F_{y'y'} u' / u$.

And so, from here, we see that w' must be equal to minus $(F_{yy} + w)'$, prime is here d by dx . So, we will write it as d by dx . So, there are other variables also minus d by dx of $(F_{y'y'}) u' / u$ minus $F_{y'y'}$, here $(u'' - u'^2 / u)$ and substituting here, we see that; we get so this adding these two F_{yy} . So we will have a $F_{yy} + w'$ will be this F_{yy} minus d by dx of $(F_{yy} + w)$ minus d by dx of $(F_{y'y'}) u' / u$ minus $F_{y'y'} (u'' - u'^2 / u)$ minus $F_{y'y'}$ u' / u double prime minus u' square over u square u' square.

And so here we see that this is nothing but over this, this is actually equal to $F_{y'y'}$ this is from here, this is equal to minus $F_{y'y'} u' / u$. So, we see that the last term here will cancel with this and simplifying this, we get the Jacobi equation. That is $(F_{yy} - d/dx F_{yy'}) u - d/dx (F_{y'y'} u') = 0$; Jacobi is equation. So, which we had already got; so, if they solution

of the Jacobi satisfies that only at A it vanishes and not before B, then we get that condition satisfied.

(Refer Slide Time: 41:56)

$$\Delta I(y) = \int_{x_1}^{x_2} F_{y'y'} \left[\frac{F_{y'y'} + W}{F_{y'y'}} dy + \delta y' \right]^2 dx$$

$$F_{y'y'} > 0 \quad \Delta I(y) > 0$$

$$F_{y'y'} < 0 \quad \Delta I(y) < 0$$

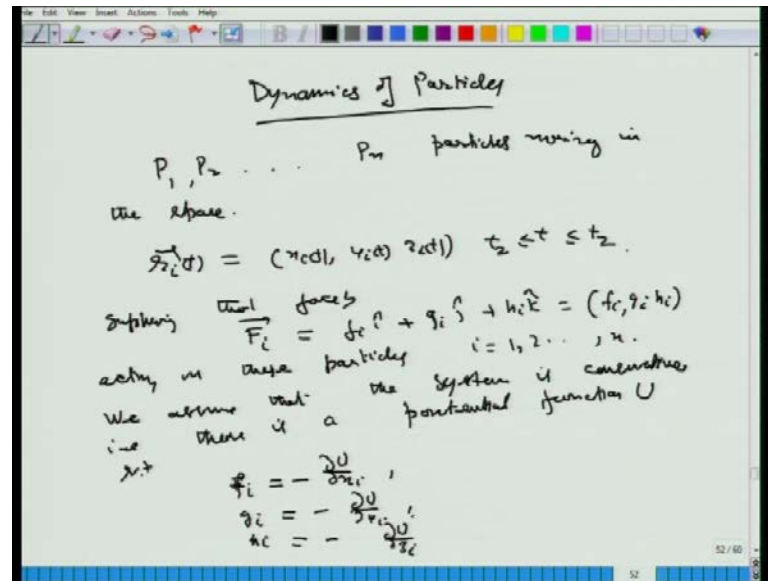

Landsender condition.

And so, next we see that here. So, using that we finally, get this delta I (y) comes out to be x_1 to x_2 $F_{y'y'}$, which we had taken out and this becomes perfect square here $F_{y'y'} + W$ over $F_{y'y'}$ plus times delta y and plus delta y prime whole is square dx.

So, clearly the sign of ... So, if $F_{y'y'}$ is positive, we get delta I (y) positive, if $F_{y'y'}$ is negative and delta I (y) negative; and so this condition is this $F_{y'y'}$ positive, this call actually Landsender condition, these conditions are called Landsender condition; is an conditions.

So, we have the Jacobi condition and Landsender conditions are satisfied, you see that we get the required results that are in the case that $F_{y'y'}$ is positive, we get strong or weak a minimum provided in the case, whether y prime is closed p to be assumed or not. Similarly, $F_{y'y'}$ negative it imply the strong or weak maximum depending upon the arbitrariness of y prime or whether it is assumed to be close to p.

(Refer Slide Time: 43:45)

So, now we have one more application that is in the mechanics, this dynamics of particles. So, here let say, there are n points p_1, p_2, p_n particles moving in this space and let say, their position vectors are $\vec{r}_i(t)$, which is $(x_i(t), y_i(t), z_i(t))$ line between t_1 to t_2 .

And so here we say consider, supposing that **that** \vec{F}_i , **\vec{F}_i** which is F_{i1} plus g_{i2} plus h_{i3} or in compact form (f_i, g_i, h_i) acting on these particles, here i equal to $1, 2$ to n . And we assume that the system is conservative that is, there is a potential function U , such that this f_i equal to minus $\frac{\partial U}{\partial x_i}$; and g_i equal to minus $\frac{\partial U}{\partial y_i}$; and h_i to minus $\frac{\partial U}{\partial z_i}$.

Handwritten notes on a digital whiteboard:

$$H(x_1, y_1, z_1, \dots, x_n, y_n, z_n) = \int_{t_1}^{t_2} (T - U) dt$$

$$T = \frac{1}{2} \sum m_i \dot{x}_i^2$$

$$U = U(x_1, y_1, z_1, \dots, x_n, y_n, z_n)$$

Hamiltonian principle says that the motion takes place along the curves where the action is least.

The system of EEs:

$$\frac{\partial}{\partial x_i} (T - U) - \frac{d}{dt} \left[\frac{\partial}{\partial \dot{x}_i} (T - U) \right] = 0$$

$$\frac{\partial}{\partial y_i} (T - U) - \frac{d}{dt} \left[\frac{\partial}{\partial \dot{y}_i} (T - U) \right] = 0$$

So, here we consider the functional H , which is function of now $x_1, x_2, x_1, y_1, z_1, x_2, y_2, z_2$ and so on x_n, y_n and z_n , these are functions of t ; and we have this t_1 to t_2 , we take $(T \text{ minus } U) dt$, where t is the kinetic energy, T is the kinetic energy given by half summation $m_i \dot{x}_i^2$; and U is the function of x_1, y_1, z_1 , and so on x_n, y_n, z_n here.

So, the Hamilton principle says that; the Hamiltonian says that the motion takes place **place** along the curves, where that the action is least is called principle of least action. So, we will established this thing, we have using the techniques of the calculus of variation. So, we need to see that here, we need to find the minimum of H . So that means, the Euler equation for this will be the system of Euler's equation of $\frac{\partial}{\partial x_i} (T \text{ minus } U) \text{ minus } \frac{d}{dt} \left[\frac{\partial}{\partial \dot{x}_i} (T \text{ minus } U) \right] = 0$. So, similarly you will have $\frac{\partial}{\partial y_i} (T \text{ minus } U) \text{ minus } \frac{d}{dt} \left[\frac{\partial}{\partial \dot{y}_i} (T \text{ minus } U) \right] = 0$.

(Refer Slide Time: 48:44)

The image shows a digital whiteboard with the following handwritten content:

$$\frac{\partial}{\partial x_i} (T-U) - \frac{d}{dt} \left[(T-U) \dot{x}_i \right] = 0$$

$$- \frac{\partial U}{\partial x_i} - m_i \ddot{x}_i = 0$$

$$\Rightarrow m_i \ddot{x}_i = F_i$$

Similarly,

$$\left. \begin{aligned} m_i \ddot{y}_i &= G_i \\ m_i \ddot{z}_i &= H_i \end{aligned} \right\} \text{Newton's laws of motion.}$$

And the last one that; del by del x_i of $(T \text{ minus } U)$ minus d by d t of $(T \text{ minus } U) \dot{x}_i$ dot partially like this. So, we get here, T is involving only here dots. So, you will have minus del U over del x_i dot del x_i minus here T is only involving the dots. So, you get minus $m_i \ddot{x}_i$ equal to 0. So, we get here this minus **minus** sign. So, here this implies that $m_i \ddot{x}_i$ equal to F_i .

Similarly, **similarly** we get $m_i \ddot{y}_i$ equal to G_i ; and $m_i \ddot{z}_i$ equal to H_i . So, these are the Newton's law, Newton's laws of motion. So, we see that which is so, this necessary condition here the Newton's laws, which are always holding and therefore, the action will be taking along those curves, where the action is least.

So, like that we have the applications of the calculus of variation in several fields' mechanics, and optics, and dynamics, and various other problems can be tackled using the calculus of techniques. So, thank you very much for viewing all this lectures, I hope that this will be very useful. Thank you very much.
