

Calculus of Variations and Integral Equation

Prof. Dharendra Bahuguna

Prof. Malay Banerjee

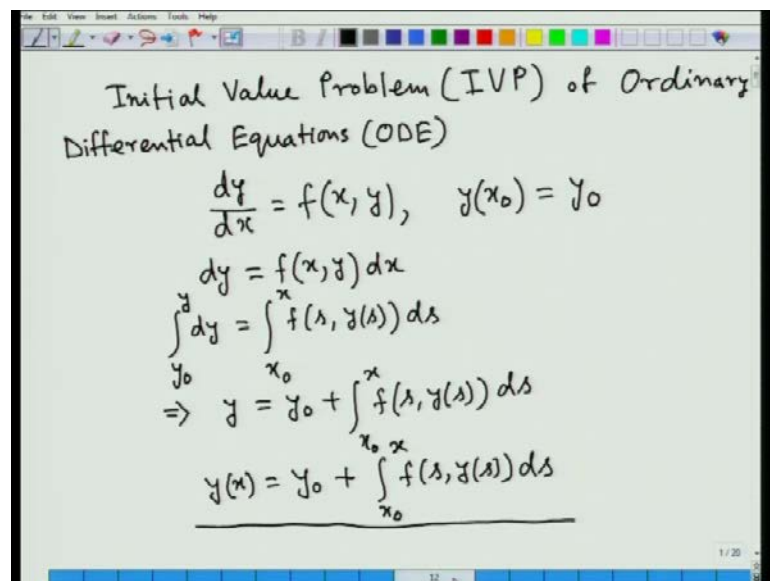

Department of Mathematics and Statics

Indian Institute of Technology, Kanpur

Lecture No. # 21

Welcome viewers to NPTEL lectures on Integral Equations. This is going to be the first lecture on Integral equation. Now, Integral Equation is a very useful tool in mathematics from your mathematical point of view as well as from applied mathematical point of view. And there are different areas where these types of Integral equations are used in a wide sense.

(Refer Slide Time: 00:58)

The image shows a handwritten derivation on a whiteboard. At the top, it reads "Initial Value Problem (IVP) of Ordinary Differential Equations (ODE)". Below this, the differential equation is given as $\frac{dy}{dx} = f(x, y)$, with the initial condition $y(x_0) = y_0$. The next step is to separate variables and integrate: $dy = f(x, y) dx$ leads to $\int_{y_0}^y dy = \int_{x_0}^x f(s, y(s)) ds$. This is then rearranged to $y = y_0 + \int_{x_0}^x f(s, y(s)) ds$. Finally, the solution is written as $y(x) = y_0 + \int_{x_0}^x f(s, y(s)) ds$.

Now, first we start with a our known formulation that is ordinary differential equation from where you can see how Integral Equation comes into the picture. For these purpose we consider, initial value problem **initial value problem**, which is usually denoted by I V P of Ordinary Differential Equations, this is in general denoted by ODE. And throughout this Lecture series I will use these I V P and ODE for Initial value problem, and ordinary differential equations.

So, first of all we consider a general first order differential equations equal to $f(x) y$ subject to the Initial condition $y(x) = y_0$. This is equal to y_0 . For these kind of equations we know how to solve this problem. Now, our intention is to convert this Initial value problem to an Integral equation. So, in order to solve it, we can write dy this is equal to $f(x) y dx$. Now, if we integrate between y equal to y_0 to y and x equal to x_0 to x then you can find y to y_0 , this is equal to $\int_{x_0}^x f(s, y(s)) ds$ from where we find y , this is equal to y_0 plus $\int_{x_0}^x f(s, y(s)) ds$.

Now, this $y(x)$ equal to y_0 plus $\int_{x_0}^x f(s, y(s)) ds$, this is actually our Integral Equation because the unknown function y here appeared under the Integral sign. Now, if y equal to $y(x)$ is a solution of this equation that is the Initial value problem then second function $y(x)$ will be a solution of this Integral equation. Now, if we just look at this equation. So, in this case we have to find out $y(x)$ such that $y(x)$ satisfies these equation.

(Refer Slide Time: 04:21)

Ex. $\frac{dy}{dx} = 2xy, y(0) = 1.$
 $y(x) = e^{x^2}$
 $y(x) = 1 + \int_0^x 2s y(s) ds$
 R.H.S. $= 1 + \int_0^x 2s e^{s^2} ds = 1 + [e^{s^2}]_0^x$
 $= e^{x^2}$

Next we will consider a particular example to verify either a solution of the Initial values problem is going to satisfy the corresponding integral equation or not. For these purpose we choose the equation $dy dx$ is equal to $2 x y$, subject it to the Initial condition y_0 this is equal to 1.

So, this is our given o d and of the season Initial problem and you can easily verify solution to this problem is given by y equal to e to the power x square. If we recall the last equation what we have constructed, once $dy dx$ equal to $f(x) y$ subject to $y(x) = y_0$

equal to $y(0)$, so, this is our Integral equation. So, corresponding to these given differential equation our integral equation will be $y(x)$ this is equal to $y(0)$ plus Integral 0 to x , $2s y(s) ds$.

Now, here we intended to verify if whether this $y(x)$ equal to e to the power x square satisfy this or not. So, for these purpose, we start with right hand side. So, this is equal to 1 plus Integral 0 to x , $2s$ now $y(s)$ is e to the power s square ds , and if we integrate it then we find 1 plus e to the power s square, Integral from limit from 0 to x . So, this is coming out to be e to the power x square which is equal to left hand side. So, that means, the solution of this Initial value problem is also a solution to the corresponding Integral equation. Now, **it is a first** it was a first order equation.

Next we consider a second order ordinary differential equation, again this is the second order Initial value problem.

(Refer Slide Time: 06:50)

The image shows a handwritten derivation on a whiteboard background. At the top, the differential equation is written as $\frac{d^2y}{dx^2} + 2\frac{dy}{dx} + y = x^2$, with initial conditions $y(0) = 1$ and $y'(0) = 0$. The derivation proceeds as follows:

- Step (i): $\frac{d^2y}{dx^2} = \phi(x)$
- Step (ii): $\frac{dy}{dx} - 0 = \int_0^x \phi(s) ds \Rightarrow \frac{dy}{dx} = \int_0^x \phi(s) ds$
- Step (iii): $y(x) - y(0) = \int_0^x \int_0^t \phi(s) ds dt$
- Final result: $y(x) = 1 + \int_0^x \int_0^t \phi(s) ds dt = 1 + \int_0^x (x-s) \phi(s) ds$

To the right of the equations is a diagram of a right-angled triangle in the s - t plane. The horizontal axis is labeled s and the vertical axis is labeled t . The hypotenuse is the line $t = x - s$. The region bounded by the axes and the line is shaded with diagonal lines.

We consider this equation $d^2y/dx^2 + 2 dy/dx + y = x^2$ with given Initial condition $y(0) = 1$ and $y'(0) = 0$, this is equal to 0. Now, at a later stage of this Lecture series I will show you directly from here after integration, how can I find out the Integral equation. Now, as it is a starting point here we just consider second derivative of y with respect to x we define it as a new function, $\phi(x)$ such that after integrating this expression twice, that means you are going to evaluate dy/dx and y in

terms of ϕ and its Integral such that the entire equation can be converted into an Integral equation.

So, this equation we can rewrite as $\frac{d}{dx} y$ this is equal to $\phi(x)$. Now, where Initial condition is given at $x = 0$, so if we integrate from 0 to x . So, then you can find $y(x) - y(0)$, this 0 is coming due to the given condition $y(0) = 0$ this is equal to $\int_0^x \phi(s) ds$. So, this actually implies $\frac{d}{dx} y$ is coming out to be $\int_0^x \phi(s) ds$, call it 2.

Again if we integrate this result after transferring dx onto the right and again from the limit 0 to x , then you can find $y(x) - y(0)$. This is equal to $\int_0^x \int_0^t \phi(s) ds dt$. Now here the range of integration is going to be x . So, we change this limit to t and we get $\int_0^x \int_0^t \phi(s) ds dt$ and these $y(0)$ is equal to 1 So, this implies $y(x)$ this is equal to 1 plus $\int_0^x \int_0^t \phi(s) ds dt$.

Now, if you look at the range of the integration in this direction we can take s in a practical direction we can take t the first limit was on ds and s is ranging from 0 to t . So, that means, we have a straight line whose equation is $s = t$. So, ds had is from 0 to t and then this limit t hiding from 0 up to the line that is $t = x$.

So, these area is actually our domain over which we are performing our integration now if we interchange the order of the Integral, then after interchanging the order of Integral we can find this is going to be 1 plus $\int_0^x (x - s) \phi(s) ds$. So, interchanging the variable of integration we will be getting this equal to y .

So, we have assume $\frac{d^2 y}{dx^2} = \phi(x)$ then from there we have derived using the given Initial condition $y(0) = 0$ $\frac{dy}{dx} = 1$ and finally, using $y(0) = 1$ we have obtained $y(x)$ equal to these 1.

(Refer Slide Time: 11:54)

The whiteboard shows the following steps:

$$1 + \int_0^x (x-s)\phi(s)ds + 2 \int_0^x \phi(s)ds + \phi(x) = x^2$$

$$\Rightarrow \phi(x) = x^2 - 1 - \int_0^x (2+x-s)\phi(s)ds$$

Boundary Value Problem (BVP)

$$\frac{d^2 y}{dx^2} + \omega^2 y = 0, \quad y(0) = 0, \quad y(\alpha) = 0$$

$$\frac{d}{dx} \left(\frac{dy}{dx} \right) = -\omega^2 y(x)$$

$$\frac{dy}{dx} - y'(0) = -\omega^2 \int_0^x y(s)ds$$

$$\Rightarrow \frac{dy}{dx} = y'(0) - \omega^2 \int_0^x y(s)ds$$

Now, if we substitute all these expressions into the given equation then you will be **will be** having 1 plus Integral 0 to x, x minus s phi s ds this is actually coming out for y then plus 2 Integral 0 to x phi s ds plus phi x, this is equal to x square and from here we can write that phi x, this is equal to x square minus 1 minus Integral 0 to x 2 plus x minus s multiplied with phi s ds.

So, in this case you can see phi is our unknown and these phi x comes under Integral sign. So, this is an integral equation corresponding to the given second order Initial value problem. Now, if y(x) is a solution to the given second order Initial value problem then second derivative of y, that is y double dot x equal to phi x will be the solution of these Integral equation. Now, so far we have considered to Initial value problem and in both the cases resulting equation comes out to be an Integral involving 0 to x within this range.

Next we consider a boundary value problem. This boundary value problem is denoted by BVP consider the second order differential equation $d^2 y / dx^2 + \omega^2 y$, this is equal to 0 subject to the given boundary conditions $y(0) = 0$, and $y(\alpha) = 0$. So, that means, we are considering this problem over the interval 0 alpha that is x ranging from 0 to alpha.

Now, in the previous example, in order to convert this type of second order differential equation to an Integral equation we have chosen $d^2 y / dx^2 = \phi(x)$. Now here

without introducing that type of function directly we can make an attempt to convert this equation to an integral equation. At a later stage of this Lecture series I will describe in which cases we have to consider what type of technique to convert the differential equation into Integral equation, but that is not a very serious question, because most of the time will be considering solution of the Integral equation.

Now, this equation can be rewritten as the $d^2 x$ of dy/dx this is well known strategy is equal to minus omega square $y(x)$. Now, if we integrate this equation from 0 to x then you can find dy/dx minus these derivative of y evaluated at y equal to 0, that is $y'(0)$ this is equal to minus omega square $\int_0^x y(s) ds$

Now, in this boundary value problem the values of y on the left hand and on the right hand are given we do not have any information for $y'(0)$. But at a later stage using this boundary condition we can find out $y'(0)$ in terms of y . So, from here we can write dy/dx this is equal to $y'(0)$ minus omega square $\int_0^x y(s) ds$.

(Refer Slide Time: 17:25)

The image shows a whiteboard with handwritten mathematical derivations. The equations are as follows:

$$y(x) - y(0) = y'(0)x - \omega^2 \int_0^x \int_0^t y(s) ds dt$$

$$\Rightarrow y(x) = y'(0)x - \omega^2 \int_0^x (x-s) y(s) ds$$

$$\frac{x=\alpha}{0 = y(\alpha)} = y'(0)\alpha - \omega^2 \int_0^\alpha (\alpha-s) y(s) ds$$

$$\Rightarrow y'(0) = \frac{\omega^2}{\alpha} \int_0^\alpha (\alpha-s) y(s) ds$$

$$y(x) = \omega^2 \frac{x}{\alpha} \int_0^\alpha (\alpha-s) y(s) ds - \omega^2 \int_0^x (x-s) y(s) ds$$

$$x-s = \frac{x}{\alpha} (\alpha-s) - \frac{s}{\alpha} (\alpha-x)$$

If we again integrate the previous expression then we can find $y(x)$ minus $y(0)$, this will be equal to $y'(0)$ multiplied by x minus omega square $\int_0^x \int_0^t y(s) ds dt$. Now, we can recall that given condition for a $y(0)$ was 0. So, from here we can write $y(x)$ is equal to $y'(0)x$ minus omega square, and again if we apply the same technique as we have adopted earlier, from here you can find $\int_0^x (x-s) y(s) ds$ still this $y'(0)$ is appeared in here.

Now, we can make an attempt to find out this $y'(0)$, if we substitute x equal to α from this result there you can find 0 this is equal to $y(\alpha)$ actually substituting x equal to α you will be having $y(\alpha)$ here and $y(\alpha)$ is given to be 0 . So, 0 equal to $y'(0)$ α minus ω^2 , $\int_0^\alpha (\alpha - s) y(s) ds$. So, from here we find $y'(0)$ that is equal to ω^2 , divided by α , $\int_0^\alpha (\alpha - s) y(s) ds$. So, if we substitute this expression here then we find $y(x)$, this is equal to ω^2 times x by α , $\int_0^\alpha (\alpha - s) y(s) ds$, this part coming for $y'(0)$ then minus ω^2 $\int_0^x (x - s) y(s) ds$.

Now, we have to proceed further in order to put this integral equation into more compact form. In order to put into more compact form we can use these identity $x - s$ this is equal to x by α times $\alpha - s$ minus s by α times $\alpha - x$, this is an identity and we are going to replace these $x - s$ with the help of this result.

(Refer Slide Time: 21:32)

The image shows a whiteboard with handwritten mathematical derivations. The top line is the original equation:
$$y(x) = \omega^2 \int_0^\alpha \frac{x}{\alpha} (\alpha - s) y(s) ds - \omega^2 \int_0^x \frac{x}{\alpha} (\alpha - s) y(s) ds + \omega^2 \int_0^x \frac{s}{\alpha} (\alpha - x) y(s) ds$$
 The second line shows the first two terms combined:
$$= \omega^2 \int_0^\alpha \frac{x}{\alpha} (\alpha - s) y(s) ds + \omega^2 \int_0^x \frac{s}{\alpha} (\alpha - x) y(s) ds$$
 The third line shows the two integrals separated by a bracket:
$$= \omega^2 \left[\int_0^x \frac{s}{\alpha} (\alpha - x) y(s) ds + \int_0^\alpha \frac{x}{\alpha} (\alpha - s) y(s) ds \right]$$
 The fourth line shows the kernel function $K(x, s)$ and the final integral form:
$$= \omega^2 \int_0^\alpha K(x, s) y(s) ds$$
 The kernel function is defined as:
$$K(x, s) = \begin{cases} \frac{s}{\alpha} (\alpha - x), & s < x \\ \frac{x}{\alpha} (\alpha - s), & x < s \end{cases}$$

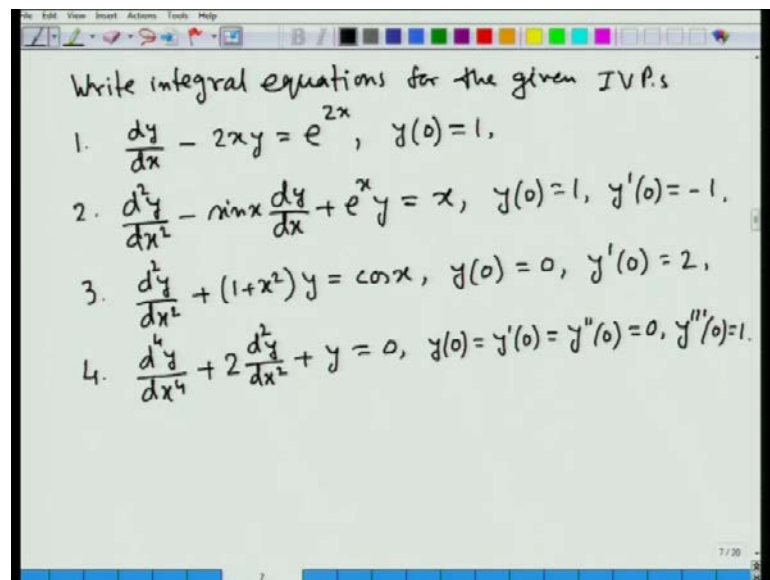

So, if we replace this $x - s$ by this identity then we find $y(s)$ equal to ω^2 times $\int_0^\alpha x$ by α **alpha** minus s ds minus ω^2 $\int_0^x x$ by α times $\alpha - s$ $y(s) ds$ plus ω^2 , $\int_0^x s$ by α times $\alpha - x$ $y(s) ds$ here I forgot to write y s , this will be $y s ds$.

Now, here range of integration is 0 to α . So, we can be derive this range of integration 0 to α by introducing a point here that is 0 to x and x to α . So, if we derive these into 0 to x and x to α then 0 to x Integral will cancel with this $e 1$, and

then we are left with this is equal to $\omega^2 \int_0^\alpha x^\alpha y^\alpha ds$ plus $\omega^2 \int_0^\alpha x^\alpha y^\alpha ds$.

So, this is equal to $\omega^2 \int_0^\alpha x^\alpha y^\alpha ds$ plus $\int_0^\alpha x^\alpha y^\alpha ds$ and this can be written into a compact form $\omega^2 \int_0^\alpha K(x, s) y(s) ds$ where this $K(x, s)$ is defined in this way. This is x^α whenever $s < x$ and this is equal to $x^\alpha y^\alpha$ for $x < s$. So, that means, $y(x)$ equal to $\omega^2 \int_0^\alpha K(x, s) y ds$; this is the integral equation corresponding to the given second order boundary value problem.

(Refer Slide Time: 25:51)

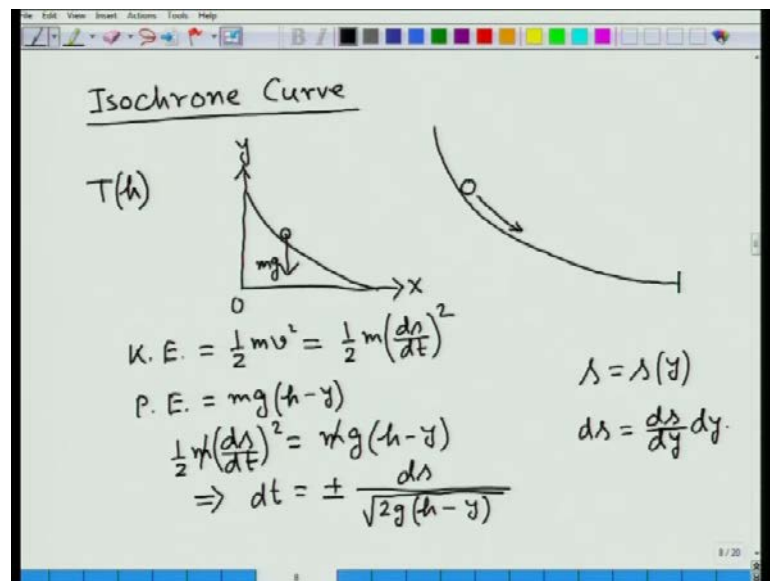

Now here I give just some exercises that you can try to convert this problem to Integral equations. So, the problem is write Integral equations for the given Initial value problems number 1 $dy/dx - 2xy = e^{2x}$ with given Initial condition $y(0) = 1$ for number 2 $d^2y/dx^2 - \sin x dy/dx + e^x y = x$ with Initial condition $y(0) = 1$, and $y'(0) = -1$. Problem number 3 $d^2y/dx^2 + (1+x^2)y = \cos x$ with given Initial condition $y(0) = 0$ $y'(0) = 2$. And problem number 4 $d^4y/dx^4 + 2 d^2y/dx^2 + y = 0$ with the given Initial conditions $y(0) = y'(0) = y''(0) = 0, y'''(0) = 1$.

equal to $y \dot{0}$ equal to $y \ddot{0}$ equal to 0, this is equal to 0, and $y \ddot{\ddot{0}}$ this is equal to 1.

So, this was all examples based upon the ordinary differential equation such that ordinary differential equations can be converted into Integral equations. Now, I give a physical example regarding the origin of Integral equation.

(Refer Slide Time: 28:49)

This integral equation is actually known as Abel's Integral Equation and this problem is related with Isochrone curve. This Isochrone curve problem is something like that you have a curve like this, a particle starts from this point it is coming down along the curve under gravitational force only, and this wire is a frictionless wire and suppose this is the point up to which this particle can come down.

So, the problem is that this Isochrone curve is the curve for which the time taken by an object sliding without friction under uniform gravity to its lowest point, this point is the lowest point is independent of its starting point. So, main problem is we have to find out the shape of the curve such that if we start from either at this position or at this position or at this position all the particles will arrive at the fixed point at the same time.

Now, let us denote capital T is the time taken by a particle coming to the lowest point from a particle height h . So, this is the h stands for a particle height through which the particle came down along this particular curve. Now, there is no friction if we look at the

geometry and relation with the coordinates you can see, this is the x axis origin, this is y axis, curve is something like this 1 and this is the position of the particle at any time T weight $m g$ acting vertically downwards. So, this height from the lowest point can be measured as the y coordinate of this particular position.

Suppose it started from a height h somewhere here, then at this point kinetic energy this is nothing but half of $m v$ square, and since the particle is coming according along a smooth curve. So, this is equal to half $m, ds dt$ whole square ds is the arc length of this particular curve at this position and potential energy, this is equal to $m g$ multiplied by the height. So, it distance and as it is a smooth curve there is no friction; therefore, kinetic energy will be equal to potential energy as per the conservation of energy is concern.

So, from there we can write half $m, ds dt$ this whole square is equal to $m g$ times h minus y , this m cancels from both side and from here we can write dt this is equal to plus minus ds divided by root over, $2 g$ times h minus y . Now, we need 1 assumption regarding the equation of this curve without any loss of genet we can assume we can find out this arc length in terms of y coordinate of the point. And then using the chain rule we can write ds equal to $ds dy$ times dy .

(Refer Slide Time: 33:48)

$$dt = \pm \frac{ds/dy}{\sqrt{2g(h-y)}} dy$$

$$dt = - \frac{ds/dy}{\sqrt{2g(h-y)}} dy$$

$$T(h) = \frac{1}{\sqrt{2g}} \int_0^h \frac{ds}{dy} \frac{dy}{\sqrt{h-y}}$$

Abel's Integral Equation

So, if we use this result here then we will be having dt this is equal to plus minus ds by dy divided by, root over $2 g$ times h minus y , dy . Now, if we just go back to the previous

picture then you can see the remaining distances this actually height decreases with the increase of time this height y remaining height this is the decreasing function with the increase in t . And therefore, we take negative sign to get this result dt equal to minus ds by dy divided by root over $2g$ into h minus y dy , and then the time required for coming to the lowest point from a height h ; that is T_h is given by 1 by root over $2g$ integral 0 to h ds dy divided by root over h minus y dy . This equation is actually called Abel's Integral Equation. This is called Abel's Integral Equation.

So, the problem is that h t is given and we are interested to find out ds dy for which the equation of the curve can be obtained, such that a particle starts from any height it will reach at the lowest point that will be independent of the height from where it has been started. So, this is 1 physical example behind the formation of Integral equation.

(Refer Slide Time: 36:32)

The image shows a digital whiteboard with handwritten mathematical definitions. At the top, it is titled "Integral Equation" and shows the general form: $y(x) = f(x) + \lambda \int_a^b k(x,s)y(s)ds$, with the condition $a \leq x, s \leq b$. Below this, three terms are defined: $f(x)$ is the given function, $k(x,s)$ is the kernel of the integral equation, and λ is the parameter. The next section is titled "Linear Integral Equation" and shows the operator form $L[y(x)] = f(x)$ and the linearity property $L[c_1 y_1(x) + c_2 y_2(x)] = c_1 L[y_1(x)] + c_2 L[y_2(x)]$. The whiteboard interface includes a toolbar at the top and a status bar at the bottom showing "10 / 20".

Now, we are in a position to give the general definition of an integral equation. In general integral equation is given by this particular format $y(x)$ is equal to $f(x)$ plus lambda times Integral a to b , $K(x, s) y(s) ds$, where a less than equal to x , s less than equal to b .

So, the problem is we had to find out $y(x)$ such that this equation is satisfied and the unknown function y is under the Integral sign, and that is why this equation is called an integral equation, and here $f(x)$ this is a given function $K(x, s)$ this is actually called

Kernel of the integral equation. This is Kernel of the integral equation and lambda, this is a parameter.

Now, in some of the problem this upper limit b maybe variable x and in some cases either lower limit or upper limit or both of them will be infinite quantities, and depending upon whether both the limits are finite real numbers or upper limit is a variable x or the limits are infinite based upon this we can classify this integral equation into different classes.

Now, before going to that I want to attract your attention towards the most important point that Linear Integral equation. The integral equation what I have written here that is actually a Linear Integral Equation, because y appeared in this equation having the first power in general, we can define the linearity property in this way entire equation can be written in the form as a operator L y(x) this is equal to f x.

If we denote this y(x) minus lambda times Integral a to b K (x, s) y s ds as L of y(x), then we can easily check for this equation it is satisfies the condition L of c 1, y 1 x plus c 2 y 2 x this is equal to c 1 L of y 1 x plus c 2 L of y 2 x, this is the linearity condition where c 1 and c 2 are 2 constants. So, this is actually the standard form of Linear Integral Equation; of course, we will be curious to know what will be the format of the non-linear Integral Equation.

(Refer Slide Time: 40:38)

$$y(x) = \int_a^x k(x,s)[y(s)]^3 ds$$

$$y(x) = f(x) + 2 \int_0^1 k(x,s)e^{y(s)} ds$$

Nonlinear
Integral
Equations.

Fredholm Linear Integral Equations

$$\psi(x) y(x) = f(x) + \lambda \int_a^b k(x,s) y(s) ds, \quad a \leq x, s \leq b$$

For $\psi(x) = 0$

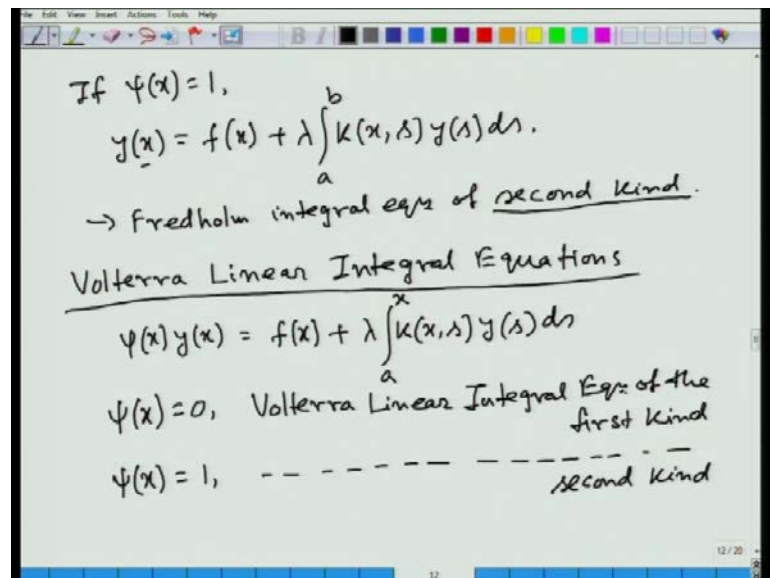

$$f(x) + \lambda \int_a^b k(x,s) y(s) ds = 0$$

→ Fredholm Lin. Integral Eqns of the first kind

I am just giving you some examples that is $y(x)$ is equal to $\int_a^x K(x, s) y(s) ds$, here the unknown function y appeared as y cube which is a non-linear function of y . And hence this is a non-linear Integral equation, another example $y(x)$, this is equal to $f(x) + 2 \int_0^1 K(x, s) y(s) ds$ this is again another example of non-linear Integral Equation s ; these are actually non-linear Integral equations.

Now, we come to the classification of different Linear Integral Equation, first we consider Fredholm **Fredholm** Linear Integral equations. (No audio from: 42:08 to 42:18) This Fredholm Linear Integral equations are written as $\psi(x) y(x) = f(x) + \lambda \int_a^b K(x, s) y(s) ds$, where $a \leq x, s \leq b$. This ψ is actually introduced here in order to classify further, this integral equation into 2 types that is Fredholm Linear Integral Equation of first kind and Fredholm Linear Integral Equation of the second kind for $\psi(x) = 0$ then will be having this integral equation of the form $f(x) + \lambda \int_a^b K(x, s) y(s) ds = 0$. This is actually Fredholm Linear Integral Equation of the first kind, this is important Fredholm Integral Equation of the first kind.

(Refer Slide Time: 44:03)

And If we take $\psi(x)$ equal to 1 then equation is $y(x)$ equal to $f(x) + \lambda \int_a^b K(x, s) y(s) ds$, this is actually Fredholm Integral Equation of second kind.

Next we consider Volterra Linear Integral Equations, these Volterra Linear Integral equations. In this case 1 limit is coming out to be a variable limit general format is $\psi(x)$, $y(x)$ is equal to $f(x)$ plus λ times Integral a to x , $K(x, s)$, $y(s)$ ds . So, this x comes out here appears here instead of earlier b . So, these type of equations are actually known as a Volterra Linear Integral equations I am not repeating the same thing, and just for your note that if $\psi(x)$, this is equal to 0. Then we will be having Volterra Linear Integral equations of the first kind, and similarly as above if $\psi(x)$ equal to 1 then we will be having Volterra Integral Equation of the second kind. So, these two things are related only with the fact that whether $y(x)$ appearing outside the Integral signs also or not. So, based upon this we can classify them into Volterra Integral Equation of first kind or second kind and Fredholm Integral Equation of the first kind or second kind.

Now, we just look at some particular features in case of Fredholm Linear Integral Equation range of integration is finite, and we have to find out this unknown function $y(x)$ in case of Volterra Integral Equation the range of integration is variable 1 upper limit is variable lower limit is fixed constant a in some problem this may be the reversed one thus lower one is a variable x upper one is some constant b .

(Refer Slide Time: 47:51)

Homogeneous Integral Equations

$$f(x) = 0$$

$$y(x) = \lambda \int_0^x (x-s)y(s) ds$$

$$y(x) = 2 \int_0^x k(x,s)y(s) ds$$

Singular Integral Equation

$$y(x) = \cos x + \int_0^{\infty} \sin(x-s)y(s) ds$$

$$y(x) = f(x) + \lambda \int_{-a}^0 e^{-(x-s)} y(s) ds, \quad y(x) = \int_0^x \frac{y(s) ds}{(x-s)^\alpha}, \quad 0 < \alpha < 1$$

Next we comes to the Homogeneous Integral equations, this Homogeneous Integral equations these are related with the appearance of $f(x)$, if $f(x)$ is identically equal to 0, then we can find Homogeneous Integral equations. So, Homogeneous Integral Equation

of Fredholm type we consider just one example that $\lambda = 0$ to 1 $x \int_0^x y(s) ds$ this is an Fredholm Homogeneous Integral Equation and $y(x)$ is equal to $2 \int_0^x K(x, s) y(s) ds$ this is an example of Volterra Integral Equation which is Homogeneous.

Next we considered another classification that is known as singular integral equation in case of singular integral equation either lower limit or upper limit or both the lower and upper limits are infinite quantities or integrand may have 1 or more singularities within the range of integration. If this happens then Integral equations are known as singular Integral equations we just consider few examples of singular Integral equations, $y(x)$ is equal to $\cos x$ plus, $\int_0^\infty \sin(x-s) y(s) ds$ this is an example of singular integral equation.

Another one is $y(x)$ equal to $f(x)$ plus $\lambda \int_{-\infty}^{\infty} \frac{y(s)}{\sqrt{x-s}} ds$ this is another singular integral equation in the first one upper limit is infinite in the second one lower limit, and upper limit both of them are infinite and another integral equation $y(x)$ is equal to $\int_0^x \frac{y(s) ds}{x-s} x^\alpha$ where $0 < \alpha < 1$. So, at a $s = x$ this integrand is infinite. So, $x = s$ is a singular point of this integrand and therefore, this is a singular Integral equation.

Solution of an integral equation

$$f(x) = \frac{1}{\pi\sqrt{x}} \text{ is a solution of } \int_0^x \frac{y(s)}{\sqrt{x-s}} ds = 1.$$

$$\int_0^x \frac{y(s)}{\sqrt{x-s}} ds = \frac{1}{\pi} \int_0^x \frac{ds}{\sqrt{x^2-s^2}}$$

$$= \frac{1}{\pi} \int_0^x \frac{ds}{\sqrt{\frac{x^2}{4} - (s-\frac{x}{2})^2}} = \frac{1}{\pi} \left[\sin^{-1} \frac{s-\frac{x}{2}}{\frac{x}{2}} \right]_0^x$$

$$= \frac{1}{\pi} [\sin^{-1}(1) - \sin^{-1}(-1)] = \frac{1}{\pi} \left[\frac{\pi}{2} - \left(-\frac{\pi}{2}\right) \right]$$

$$= 1$$

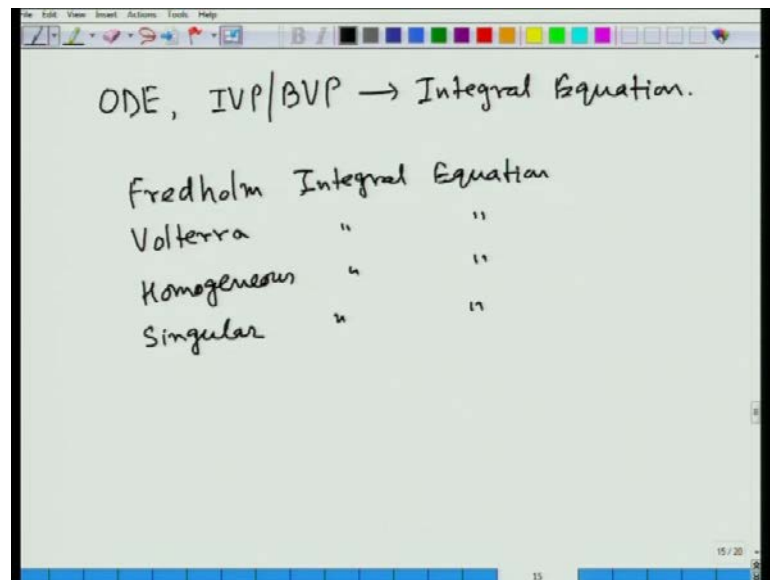

Finally for today we just consider one problem, that is solution of an integral equation. We are not going to solve any integral equation rather we can verify that a given function

satisfies an Integral equation. Here we are going to verify that $f(x)$ equal to $\frac{1}{\sqrt{x}}$ is a solution of the integral equation given by $\int_0^x \frac{y(s)}{\sqrt{x-s}} ds$ this is equal to 1.

So, in order to verify this we start from here. $\int_0^x \frac{y(s)}{\sqrt{x-s}} ds$. So, substituting for $y(s)$ equal to $\frac{1}{\sqrt{s}}$ we can find this is equal to $\int_0^x \frac{1}{\sqrt{s}\sqrt{x-s}} ds$ divided by \sqrt{x} this is equal to $\frac{1}{\sqrt{x}} \int_0^x \frac{1}{\sqrt{s}\sqrt{x-s}} ds$ divided by \sqrt{x} square by $4 - s - x$ by 2 this whole square this is equal to $\frac{1}{\sqrt{x}} \sin^{-1} \frac{s-x}{2}$ whole divided by x by 2 and limit 0 to x . So, this is equal to $\frac{1}{\sqrt{x}}$ after substituting the limit will be having $\sin^{-1} \frac{1-x}{2}$ minus $\sin^{-1} \frac{-1-x}{2}$. Considering principle values of this inverse function, we find this is equal to $\frac{1}{\sqrt{x}} \left(\frac{\pi}{2} - \left(-\frac{\pi}{2} \right) \right)$.

So, this is equal to 1, so that means, the function $f(x)$ equal to $\frac{1}{\sqrt{x}}$ satisfies this integral equation, where y was the unknown, and this $\frac{1}{\sqrt{x}}$ this is the solution of this Integral equation.

(Refer Slide Time: 55:07)

So, just in order to sum up first of all today we have seen that how ordinary differential equations, they are either Initial value problem or boundary value problems that can be converted into Integral equations. Then we have considered a physical problem behind the formation of the integral equation, and after that we have classified different types of Integral equations.

We are considered Fredholm Integral equations, these are of 2 types it is first kind and second kind, then Volterra Integral equations **Volterra Integral equations** and then we have had a look at Homogeneous Integral equations, and finally we had a look at the Singular Integral questions. Now, in rest of the lectures most of the time we will be considering Linear Integral equations only, and at the end I just give one Lecture on the solution of non-linear Integral equations.
