Lecture No. # 23

Welcome viewers to the third lecture, for the lecture series on Integral Equation under NPTEL. In the second lecture, we have discussed the Leibnitz rule, that is let us use to convert the integral equation to ordinary differential equation. And we solved the ordinary differential equations, and verified that obtained solutions also satisfies the given integral equation. Next, we have considered the detailed proof of generalized replacement lemma.

(Refer Slide Time: 01:11)

Generalized Replacement Lemma

$$\int_a^x \int_a^{s_1} \int_a^{s_2} \dots \int_a^{s_{n-1}} g(s) ds_1 ds_2 \dots ds_{n-1} = \frac{1}{(n-1)!} \int_a^x (x-s)^{n-1} g(s) ds$$
$$\frac{d^2 y}{dx^2} + p(x) \frac{dy}{dx} + q(x) y = r(x), \quad y(a) = \alpha, \quad y'(a) = \beta$$

$p(x), q(x), r(x)$ are defined and continuous over $a \leq x \leq b$

$$\frac{d}{dx} \left[y'(x) \right] = -p(x) y'(x) - q(x) y(x) + r(x)$$
$$\Rightarrow y'(s) \Big|_a^x = - \int_a^x p(s) y'(s) ds - \int_a^x q(s) y(s) ds + \int_a^x r(s) ds$$

This generalized replacement lemma, we today again try to recall. Generalized replacement lemma, in terms of mathematical notations, this is integral from a to x, a to s n minus 1, integral a to s n minus 2, a to s 2, integral a to s 1, g s d s 1 d s 2 up to d s n minus 1. This multiple integral is equal to 1 by factorial n minus 1 integral a 2 x x minus s whole to the power n minus 1 g s d s. This was the generalized replacement lemma.

Now, we use this generalized replacement lemma in order to convert second and higher order ordinary differential equations into Volterra integral equation of the second kind. At the first two lectures, we have seen some examples that how second or higher order linear ordinary differential equations can be converted into an integral equation. Now, in this lecture we start with a general second order linear ordinary differential equation which is an initial value problem.

So, first we consider the ordinary differential equation that is given by $\frac{d^2 y}{dx^2} + p(x) \frac{dy}{dx} + q(x)y = r(x)$. This is the given differential equation subjected to the initial condition $y(a) = \alpha$, $y'(a) = \beta$. Now, in this equation $p(x)$, $q(x)$ and $r(x)$ these 3 functions are known functions. These 3 functions $p(x)$, $q(x)$, $r(x)$, they are actually defined and continuous over, $a \leq x$ and $x \leq b$.

Now, our target is to convert this ordinary differential equation into an integral equation and in the process of construction of these equivalent integral equation from these ordinary differential equation, you can see that these two given initial conditions will be absorbed into the different steps of the formation of the integral equation. So, first of all we can rewrite these given ordinary differential equation into the form, that is $\frac{d}{dx} \left(\frac{dy}{dx} \right) + p(x) \frac{dy}{dx} + q(x)y = r(x)$ as per the given conditions on p, q, r this right hand side is an integral function.

So, we are actually intended to integrate both sides from the limit a to x and seems x is already involved into the equation and of course, x is the independent variable and we are going to integrate from a to x . So, what we can do we can rewrite these expressions where x is replaced by s . So, these dx will come out to be ds , and then we integrate from the range $s = a$ to $2s = x$. So, after integration it will come into this particular form that $y'(x) - y'(a) = \int_a^x [-p(s)y'(s) - q(s)y(s) + r(s)] ds$.

Now on the left hand side it will be $y'(x) - y'(a)$ and $y'(a)$ is already given this is β . So, left hand side will be $y'(x) - \beta$, and we can shift these β onto the right hand side in order to get the result that $\frac{dy}{dx}$, which stands for $y'(x)$, this is

equal to beta, minus integral a to x p s y dot s d s minus integral a to x q s y s d s plus integral a to x r s d s.

(Refer Slide Time: 07:37)

The image shows a whiteboard with handwritten mathematical derivations. The equations are as follows:

$$\frac{dy}{dx} = \beta - \int_a^x p(s)y'(s) ds - \int_a^x q(s)y(s) ds + \int_a^x r(s) ds$$

$$= \beta - \left[p(s)y(s) \right]_a^x + \int_a^x p'(s)y(s) ds - \int_a^x q(s)y(s) ds + \int_a^x r(s) ds$$

$$= \beta + \alpha p(a) - p(x)y(x) + \int_a^x [p'(s) - q(s)]y(s) ds + \int_a^x r(s) ds$$

$$y(x) = \alpha + [\beta + \alpha p(a)](x-a) - \int_a^x p(s)y(s) ds + \int_a^x \int_a^{s_1} [p'(s) - q(s)]y(s) ds ds_1 + \int_a^x \int_a^{s_1} r(s) ds ds_1$$

$$= \alpha + [\beta + \alpha p(a)](x-a) - \int_a^x p(s)y(s) ds + \int_a^x (x-s) [p'(s) - q(s)]y(s) ds + \int_a^x (x-s) r(s) ds$$

Now, we are just going to integrate these integral using the formula for integration by parts. If we integrate these integral using the formula for integration by parts, then will be having beta, minus p s y s. Actually we were considering these y dot s, as p and p as u. Limit from a to x, then it will be plus integral a to x p dashed s y s d s plus integral **sorry** this will be minus a to x q s y s d s plus integral a to x r s d s. And once you substitutes this lower limit this is a constant and you can recall y at s equal to a, it is given p s is a known function. So, after substituting s equal to a, this will also be a known quantity. So, will be having this constant time that is beta plus alpha p a, this quantity minus p x y x plus integral a to x p dashed s, minus q s, this multiplied by y s d s, plus integral a to x r s d s. So, this is actually expression for d y d x equal to these one.

So, now, before proceeding further, I just want to draw your attention. If you look at this mathematical expression and this is also an equation. Equation in terms of the unknown y, now in this equation derivative of y is involved here on the left hand side, again the unknown function y appears under the integral sign. So, the question is what type of equation is it. It is actually known as integral differential equation, where in the equation derivative of y is involved again integral of y is also involved. After few lectures, we will

be discussing little bit about this into differential equations, this is just for your information at this moment.

Now, again if we integrate this result that is dy/dx equal to given by this one, then after integration from a to x within this range will find $y(x) - y(a)$, $y(a) = \alpha$, we can transfer this α to the right hand side to get $\alpha + \beta + \alpha p a$, it is multiplied with $x - a$, minus integral a to x $p(s)y(s)ds$ plus integral a to x , **sorry** this will be a to x , **a to x** a to s $p(s) \cdot s - q(s)y(s)ds + 1$, this plus integral a to x integral a to s $1 r(s)ds + 1$.

Now, in last two integrals, we have to apply the generalized replacement formula. After applying generalized replacement formula, we will be having this $\alpha + \beta + \alpha p a$ into $x - a$, this will remains unaltered integral a to x $p(s)y(s)ds$, this will be plus integral a to x $x - s$ $p(s) \cdot s - q(s)y(s)ds$ plus last integral will be integral a to x $x - s$ $r(s)ds$.

Now, you can see first two terms, that is $\alpha + \beta + \alpha p a$ into $x - a$, this is known quantity, $r(s)$ is a given function. So, you can find out a to x $x - s$ $r(s)ds$, and third and fourth term involving y , these actually involves the unknown quantity y .

(Refer Slide Time: 14:45)

The image shows a whiteboard with handwritten mathematical derivations. The equations are as follows:

$$y(x) = f(x) + \int_a^x k(x,s)y(s)ds$$

$$f(x) = \alpha + [\beta + \alpha p(a)](x-a) + \int_a^x (x-s)r(s)ds$$

$$k(x,s) = (x-s)(p'(s) - q(s)) - p(s)$$

Ex. $\frac{d^2y}{dx^2} - \sin x \frac{dy}{dx} + e^x y = x, \quad y(0) = 1, \quad y'(0) = -1$

$$f(x) = 1 + [-1]x + \int_0^x (x-s)s ds = 1 - x + \frac{x^3}{6}$$

$$k(x,s) = (x-s)[- \cos s - e^s] + \sin s = \sin s - (x-s)(\cos s + e^s)$$

So therefore, we can write this expression into the form $y(x) = f(x) + \int_a^x k(x,s)y(s) ds$, where this $f(x)$ is equal to this expression that is $\alpha + \beta + \alpha \int_a^x r(s) ds$. And from the previous light, you can see that this entire expression $p \dot{s} - q s$ multiplied by $x - s$, and minus $p s$ these actually give you the targeted kernel of the integral equation that is $k(x,s)$. And hence the kernel of the integral equation $k(x,s)$, that is given by $(x-s)$ multiplied with $p \dot{s} - q s - p s$.

So, this is our target integral equation that we have obtained starting from the given general form of second order ordinary differential equation which is an initial value problem.

We can just have a look at one example; that means, we had to construct the integral equation corresponding to this differential equation $y'' - x y' + e^x y = x$, where $y(0) = -1$. So, if we compared with our general format for the second order ordinary differential equation then you can see $p(x)$ is $-x$ known function, $q(x)$ equal to e^x , α is equal to 1 , and β this is equal to -1 .

So, quickly if we substitute this expression into this formula, then we can find $f(x)$, this is equal to $1 + \beta$ is -1 ; now, $p(x)$ is $-x$, a is 0 , so that means, $\int_a^x p(x) dx$ is 0 . So, no contribution is coming from $\alpha \int_a^x r(s) ds$ only, because a is 0 plus $\int_a^x r(s) ds$ here a is 0 . So, lower limit will be 0 to x , $r(x)$ is x . So, $\int_a^x r(s) ds$ will be $\int_0^x s ds$. And after evaluating this integral, you can find $\frac{1}{2} x^2$, first term $\int_a^x k(x,s) ds$, after integration will give you, $\frac{1}{6} x^3 - \frac{1}{2} s^2$ from 0 to x , will give you $\frac{1}{6} x^3 - \frac{1}{6} x^3$.

So, after simplification this will be equal to $\frac{1}{6} x^3$ and similarly, if you calculate the kernel of this integral equation. So, this will be $(x-s)$, multiplied with $p \dot{s} - q s - p s$ is $-x - s$, so, that means, it will be $-x - s$, then q is to the power s , so, that means, $e^s - x - s$. So, it will be $e^s - x - s$. So, this is equal to $(x-s)(e^s - x - s)$, multiplied the $\cos s$, plus e^s .

Now, here I substitute these expressions into this easily available formula written here, but in terms of the practical problem and you have to attend, then you have proceed step

by step but the way out will be these 1. Of course, this strategy can be applied to higher order ordinary differential equations also, and here I just consider another example on higher order linear differential equation, ordinary differential equation where initial condition is given. But you to keep in mind that formulation of a general result that what will be the resulting voltera integral equation from a given n th order ordinary differential equation with a little bit difficult problem.

And we can attack that problem using the strategy what we have adopted earlier, if recall from the first lecture that equations integral equations was constructed from the differential equation, where given equation was of the order second order differential equation, we have started with $d^2 y / dx^2 = \phi(x)$. And from there we have calculated dy/dx and y in terms of ϕ and substituted into the original equation in order to get the resulting integral equation. That point I will come later after this example.

(Refer Slide Time: 21:34)

The image shows a whiteboard with handwritten mathematical work. At the top, it says "Ex" followed by the differential equation $\frac{d^3 y}{dx^3} - \frac{d^2 y}{dx^2} + \frac{dy}{dx} - y = x$, with initial conditions $y(0) = y'(0) = 0, y''(0) = 1$. The derivation proceeds as follows:

$$\frac{d}{dx} \left(\frac{d^2 y}{dx^2} \right) = \frac{d^2 y}{dx^2} - \frac{dy}{dx} + y + x$$

$$\frac{d^2 y}{dx^2} = 1 + \frac{x^2}{2} + y'(x) - y(x) + \int_0^x y(s) ds$$

$$\frac{dy}{dx} = x + \frac{x^3}{6} + y(x) - \int_0^x y(s) ds + \int_0^x \int_0^{s_1} y(s_2) ds_2 ds_1$$

$$y(x) = \frac{x^2}{2} + \frac{x^4}{24} + \int_0^x y(s) ds - \int_0^x \int_0^{s_1} y(s_2) ds_2 ds_1 + \int_0^x \int_0^{s_2} \int_0^{s_3} y(s_4) ds_4 ds_3 ds_2$$

$$= \frac{x^2}{2} + \frac{x^4}{24} + \int_0^x [1 - (x-s) + \frac{1}{2}(x-s)^2] y(s) ds$$

Now, here and in the example is $d^3 y / dx^3$ minus $d^2 y / dx^2$ plus dy / dx , minus y , this is equal to x , where given initial conditions are, $y(0) = y'(0) = 0$, this is a equal to 0, and $y''(0)$ is equal to 1. So, if we proceed a similar manner, that first of all from the give any question we can write $d^2 y / dx^2$, that is equal to integral **sorry** it will be equal to $d^2 y / dx^2$, minus dy / dx , plus y , plus x .

Now, we have to integrate these from 0 to x . So, after integration you can find $d^2 y / dx^2$ minus dy / dx at x equal to 0 this is 1. So, you can transferred this 1 on the right

hand side, and after that we can write integral of these term that is x from the range 0 to x . So, it will be, x square by 2 , plus integral of this expression that is $d^2 dx^2$. So, it will results in $y \cdot x$, minus 0 , because $y \cdot 0$ is equal to 0 , then minus $y \cdot x$ plus 0 , because $y \cdot 0$ is given here exactly equal to 0 , plus integral 0 to x , $y \cdot s \cdot ds$.

Again you can write the left hand side in terms of dt of dx and again after integration you can find from here $dy \cdot dx$, this is equal to no constant term will be adjusted either on the left or right, because $dy \cdot dx$ at x equal to 0 . So, this is equal to x plus, x cube by 6 , plus integral of $y \cdot dx$, that is equal to $y \cdot x$ minus 0 , minus integral 0 to x , $y \cdot s \cdot ds$ and this will be change to 0 to x 0 to s 1 $y \cdot s \cdot ds$ ds 1 . Again integrating from 0 to x , you can find $y \cdot x$, this is equal to x square by 2 plus x to the power 4 by 24 plus integral 0 to x $y \cdot s \cdot ds$ minus integral 0 to x integral 0 to s 1 $y \cdot s \cdot ds$ ds 1 plus integral 0 to x integral 0 to s 2 integral 0 to s 1 $y \cdot s \cdot ds$ ds 1 ds 2 .

Now, in these 2 last integrals, we had to apply generalized replacement formula. So, after applying that formula we can find this will be equal to x square by 2 plus x to the power 4 by 24 plus integral 0 to x $y \cdot s \cdot ds$ minus integral 0 to x x minus s $y \cdot s \cdot ds$ plus integral 0 to x x minus s whole square by factorial 2 $y \cdot s \cdot ds$.

So, ultimately this is equal to the integral equation x square by 2 , plus x to the power 4 by 24 , plus integral 0 to x 1 minus x minus s plus half of x minus s whole square these multiplied with $y \cdot s \cdot ds$. So, this is actually our resulting integral equation. So, this part x square by 2 plus x to the power 4 by 24 , this is equal to your $f(x)$ and 1 minus x minus s plus half of s minus 2 whole square, this is actually the kernel of the integral equation.

(Refer Slide Time: 27:33)

$$\frac{d^n y}{dx^n} + p_1(x) \frac{d^{n-1} y}{dx^{n-1}} + p_2(x) \frac{d^{n-2} y}{dx^{n-2}} + \dots + p_{n-1}(x) \frac{dy}{dx} + p_n(x) y = q(x),$$

$$y(a) = \alpha_0, y'(a) = \alpha_1, y''(a) = \alpha_2, \dots, y^{(n-1)}(a) = \alpha_{n-1}$$

$$p_r(x), 1 \leq r \leq n, q(x) \quad x \in [a, a_1]$$

$$\frac{d^n y}{dx^n} = u(x) \quad \dots \quad (i)$$

$$\frac{d^{n-1} y}{dx^{n-1}} - \alpha_{n-1} = \int_a^x u(s) ds$$

$$\frac{d^{n-1} y}{dx^{n-1}} = \int_a^x u(s) ds + \alpha_{n-1} \quad \dots \quad (ii)$$

Next, we consider the formulation of integral equation starting from a given n th order ordinary differential equation with n initial conditions those are also prescribed. Now, we consider this equation that $d^n y/dx^n + p_1(x) d^{n-1} y/dx^{n-1} + p_2(x) d^{n-2} y/dx^{n-2} + \dots + p_{n-1}(x) dy/dx + p_n(x) y = q(x)$. And given initial conditions are $y(a) = \alpha_0, y'(a) = \alpha_1, y''(a) = \alpha_2, \dots, y^{(n-1)}(a) = \alpha_{n-1}$.

And all these functions that is $p_r(x)$ where $1 \leq r \leq n$ and $q(x)$, they are defined and continuous over some closed interval of x , starting from the left at a and on the right, ending let say a_1 . Now, our target is convert these general linear n th order ordinary differential equation, where in initial conditions are prescribed, convert it to a volterra integral equation, and during the process of this transformation you have to be careful about the notation at every steps.

Let us start with the assumption in this case, we have to assume $d^n y/dx^n = u(x)$. Now, this equation possesses a solution. That means, they exist at y which is continuously n times differentiable, satisfies this equation which is a solution of this equation and therefore, n th derivative of y with respect to s is equal to $u(x)$, that is also continuous. So, we can integrate it from the limit a to x in order to get the result $d^{n-1} y/dx^{n-1} = \int_a^x u(s) ds + \alpha_{n-1}$.

minus 1 y, d x n minus 1, minus these derivatives evaluated at a, that means, y n minus 1 a, this is equal to alpha n minus 1, and this is equal to integral a to x, u s, d s, this 1.

Next we can transfer this quantity onto the right hand side to get the result d n minus 1 y, d x n minus 1, that is equal to integral a to x u s d s plus alpha n minus 1, we call this expression as 1 this as 2. Now, we are going to integrate this second result, that is d n y by d x n minus 1 equal to this expression from a to x.

(Refer Slide Time: 31:49)

The image shows three lines of handwritten mathematical work on a whiteboard. The first line shows the derivative of y with respect to x raised to the power n-2, equated to a double integral of u(s) from a to x and a to s1, plus terms alpha_{n-1}(x-a) and alpha_{n-2}. The second line shows the derivative of y with respect to x raised to the power n-3, equated to a triple integral of u(s) from a to x, a to s2, and a to s1, plus terms alpha_{n-1}((x-a)^2/2), alpha_{n-2}(x-a), and alpha_{n-3}. The third line shows the derivative of y with respect to x raised to the power n-k, equated to a k-fold integral of u(s) from a to x, a to s_{k-1}, ..., a to s1, plus terms alpha_{n-1}((x-a)^{k-1}/(k-1)!), alpha_{n-2}((x-a)^{k-2}/(k-2)!), ..., alpha_{n-k}.

Once we integrate then we can find d n minus 2 y, d x n minus 2, equal to the constant evaluated at x equal to 0, that is alpha n minus 2, can be transformed onto the right hand side and then we will be having integral a to x, integral a to s 1, u s d s d s 1, plus alpha n minus 1, x minus a, plus alpha n minus 2. Remember this alpha n minus 2, coming from the left hand side and applying the formula, we can find, this is equal to integral a to x, x minus s, u s, d s, plus, alpha n minus 1, x minus a, plus, alpha n minus 2, call it 2, **sorry** it will be 3, because last question was 2.

Now, we integrate not the exactly expression d n minus 2 y, d x n minus 2, equal to this 1, rather we are integrating the first expression that is d n minus 2 y by d x n minus 2 equal to double integral this 1, such that after introducing the integral sign we can apply the general replacement formula. So, using that technique we can find d n minus 3 y, d x n minus 3, this will be equal to, integral from a to x, integral a to s 2, integral a to s 1, u s d s d s 1 d s 2.

Now, this term that is $\alpha^{n-1} (x-a)$, after integration from a to x , will produce, $(x-a)^2$, by factorial 2, here we will find $\alpha^{n-2} (x-a)$, plus, α^{n-3} , that actually come from the left hand side. So, ultimately this is equal to, $\frac{1}{2!} \int_a^x (x-s)^2 ds$, plus, $\alpha^{n-1} (x-a)^2$, plus $\alpha^{n-2} (x-a)$, plus α^{n-3} , call it 4.

Now, you just have a look at the analogy of this order of the derivative and suffixes appearing here. In case of $n-2$, when order of the derivative is $n-2$, so, constant is going up to $n-2$, $\alpha^{n-1} \alpha^{n-2}$. When it is $n-3$ th order derivative is involved then $\alpha^{n-1} \alpha^{n-2}$, up to α^{n-3} , and in this case, $(x-s)$ whole to the power 1; in this case $(x-s)^2$, so that means, at the k th step, we can find this result that, $\frac{d^{n-k} y}{dx^{n-k}}$, that will be equal to...

Now just try to understand when 3 is here that is $n-3$. So, we have $\frac{1}{2!} (x-s)^2$ and $(x-s)^2$, when this is $n-2$, so 2 is here. So, this is only $\frac{1}{1!}$ factorial, we can assume this expression is $\frac{1}{1!} (x-s)$ whole to the power 1. So, in case $n-k$, we will be having $\frac{1}{(k-1)!} \int_a^x (x-s)^{k-1} ds$.

And then we will be having $\alpha^{n-1} (x-a)^{k-1}$, here it will be $\frac{1}{(k-1)!} \alpha^{n-2} (x-a)^{k-2}$, by factorial $(k-2)$, plus dot. Last but one term will be plus, $\alpha^{n-k+1} (x-a)$ and last one will be α^{n-k} .

So, here it was α^{n-3} , when we have the $n-3$ th order derivative of y on the left hand side, here it was α^{n-2} , last constant term, where left hand side we have the derivative of $n-2$ th order. So, in case of $n-k$, last constant will be α^{n-k} , we call this expression as 5.

So, proceeding in this way we can arrive at the second order, first order as well as only y , from here by taking k equal to $n-2$, k equal $n-1$, and finally, k equal to n , but here I am writing the result only for $\frac{dy}{dx}$ and y only.

(Refer Slide Time: 38:45)

The image shows a whiteboard with handwritten mathematical derivations. At the top, a linear differential equation is written: $\frac{d^n y}{dx^n} + p_1(x) \frac{d^{n-1} y}{dx^{n-1}} + p_2(x) \frac{d^{n-2} y}{dx^{n-2}} + \dots + p_{n-1}(x) \frac{dy}{dx} + p_n(x)y = q(x)$. Below this, initial conditions are given: $y(a) = \alpha_0, y'(a) = \alpha_1, y''(a) = \alpha_2, \dots, y^{(n-1)}(a) = \alpha_{n-1}$. The domain is specified as $x \in [a, a_1]$. The derivation then shows the reduction of the equation to a first-order form: $\frac{d^n y}{dx^n} = u(x)$ (i). This is integrated to get $\frac{d^{n-1} y}{dx^{n-1}} - \alpha_{n-1} = \int_a^x u(s) ds$. A second integration yields $\frac{d^{n-1} y}{dx^{n-1}} = \int_a^x u(s) ds + \alpha_{n-1}$ (ii).

So, $\frac{d y}{d x}$, this will be equal to, $\frac{1}{(n-2)!} \int_a^x (x-s)^{n-2} u(s) ds + \frac{\alpha_{n-1}}{(n-2)!} (x-a)^{n-2}$, plus $\frac{\alpha_{n-2}}{(n-3)!} (x-a)^{n-3}$, plus dot dot.

Proceeding in this way, last but one term will be, $\frac{\alpha_2}{2!} (x-a)^2 + \frac{\alpha_1}{1!} (x-a) + \alpha_0$. Again integrating this expression you can find $y(x)$ is equal to, $\frac{1}{(n-1)!} \int_a^x (x-s)^{n-1} u(s) ds + \frac{\alpha_{n-1}}{(n-1)!} (x-a)^{n-1} + \frac{\alpha_{n-2}}{(n-2)!} (x-a)^{n-2} + \dots + \frac{\alpha_2}{2!} (x-a)^2 + \frac{\alpha_1}{1!} (x-a) + \alpha_0$. This α_0 is coming from the left hand side because $y(x) - y(a)$, $y(a)$ is given to be α_0 . So, this α_0 will come to the right hand side.

So, last equation we numbered it as 5. So, this will be 6 and this is 7. So, we have all the expressions starting from $\frac{d y}{d x}$, $\frac{d^2 y}{d x^2}$, up to $\frac{d^n y}{d x^n}$, in terms of u . So, now, we are going to substitute all these expressions into the original given ordinary differential equation this one and after transferring $(n-1)$ th derivative of y up to y term onto the right hand side.

(Refer Slide Time: 41:37)

$$\frac{dy}{dx} = \frac{1}{n-2} \int_a^x (x-s)^{n-2} u(s) ds + \alpha_{n-1} \frac{(x-a)^{n-2}}{n-2} + \alpha_{n-2} \frac{(x-a)^{n-3}}{n-3} + \dots$$

$$+ \dots + \alpha_2 (x-a) + \alpha_1 \dots \text{---(vi)}$$

$$y(x) = \frac{1}{n-1} \int_a^x (x-s)^{n-1} u(s) ds + \alpha_{n-1} \frac{(x-a)^{n-1}}{n-1} + \alpha_{n-2} \frac{(x-a)^{n-2}}{n-2}$$

$$+ \dots + \alpha_2 \frac{(x-a)^2}{2} + \alpha_1 (x-a) + \alpha_0 \dots \text{---(vii)}$$

$$\frac{d^n y}{dx^n} = -p_1(x) \frac{d^{n-1} y}{dx^{n-1}} - p_2(x) \frac{d^{n-2} y}{dx^{n-2}} - \dots - p_{n-1}(x) \frac{dy}{dx} - p_n(x) y + q(x)$$

$$u(x) = f(x) + \int_a^x k(x,s) u(s) ds$$

So, that means, we are rewriting the equation into this form. $\frac{d^n y}{dx^n}$, this is equal to $-p_1(x) \frac{d^{n-1} y}{dx^{n-1}} - p_2(x) \frac{d^{n-2} y}{dx^{n-2}} - \dots - p_{n-1}(x) \frac{dy}{dx} - p_n(x) y + q(x)$, in this way ultimately $\frac{d^n y}{dx^n}$, this is equal to $u(x)$ state for what. Now first of all we try to collect the terms which does not involve integral of use.

So, try to understand this point. First of all you will be having this term $q(x)$, then this entire expression in 7, that is $\alpha_{n-1} (x-a)^{n-1} / (n-1) + \alpha_{n-2} (x-a)^{n-2} / (n-2) + \dots + \alpha_2 (x-a)^2 / 2 + \alpha_1 (x-a) + \alpha_0$, this will be multiplied by $p_n(x)$, then in expression 6, except the integral, entire expression will be multiplied with $p_n(x)$, proceeding in this way, finally, this $\alpha_{n-1} (x-a)^{n-1} / (n-1)$, it will be multiplied with $p_n(x)$.

So, what we can do, we can just claim that after collecting this term, we will be having an expression $f(x) + \int_a^x k(x,s) u(s) ds$. Now the task is we have to write what is $f(x)$ and what is $k(x,s)$. Now, just recall from here, first of all this $\alpha_{n-1} (x-a)^{n-1} / (n-1)$, **this $\alpha_{n-1} (x-a)^{n-1} / (n-1)$** it will be multiplied with $p_n(x)$. So, which gives u ultimately,

(Refer Slide Time: 44:28)

$$\begin{aligned}
 f(x) &= q(x) - \alpha_0 p_n(x) - \alpha_1 [(x-a)p_n(x) + p_{n-1}(x)] \\
 &\quad - \alpha_2 [-] - \dots - \alpha_{n-1} [p_1(x) + (x-a)p_2(x) \\
 &\quad + \frac{(x-a)^2}{2} p_3(x) + \dots + \frac{(x-a)^{n-1}}{(n-1)} p_n(x)] \\
 k(x,s) &= -p_1(x) - p_2(x)(x-s) - p_3(x) \frac{(x-s)^2}{2} - \dots \\
 &\quad - p_{n-1}(x) \frac{(x-s)^{n-2}}{(n-2)} - p_n(x) \frac{(x-s)^{n-1}}{(n-1)} \\
 &= - \sum_{r=1}^n \frac{(x-s)^{r-1}}{(r-1)} p_r(x)
 \end{aligned}$$

This $f(x)$ equal to, $q(x)$ minus just see α_0 will appear only with $y(x)$. So, first of all we can write the coefficient of α_0 now α_0 will be multiplied the $p_n(x)$. So, therefore, it will be minus $\alpha_0 p_n(x)$. Then α_1 will come from only expression of $y(x)$ and dy/dx . So, α_1 , this $x - a$, it will be multiplied with p_n and α_1 will be multiplied with $p_n - 1$. So, therefore it will be minus α_1 , then $x - a$, multiplied with $p_n(x)$, plus $p_{n-1}(x)$.

Then you can write the coefficient of α_2 , it will be 1 expression, proceeding in this way last term will be α_{n-1} and now just see what is the expressions will be involved from, the first 1, this α_{n-1} , will be multiplied with $p_1(x)$. Then from the second 1 α_{n-1} this $x - a$ will be multiplied with $p_2(x)$, then $x - a$ whole square by factorial 2 this will be multiplied with $p_3(x)$.

So, proceeding in this way we will be having this $p_1(x)$, plus $x - a$, plus $x - a$ whole square by factorial 2, $p_3(x)$, plus dot, last term will be, $x - a$ whole to the power $n - 1$, by factorial $n - 1$, $p_n(x)$. This is actually expression for $f(x)$. And just recall $q(x)$, $p_n(x)$, $p_{n-1}(x)$, up to $p_1(x)$, all these quantities are known quantities, as well as the given quantities to this is completely a known function.

Now, what will be the structure the kernel, $k(x, s)$, is actually collection of the integrand involved with $y(s)$. So, from the first 1 you'll be having just minus $p_1(s)$. Then from the second 1, $p_2(s)$ multiplied with $x - s$, then $p_3(s)$ multiplied with

this one. So, proceeding in this way ultimately we will be having this expression that is $(x-s)^{p-1} x$, $(x-s)^{p-2} x$, it will be multiplied with $(x-s)$, $(x-s)^{p-3} x$, $(x-s)$ a whole square, by factorial 2, \dots , last but one term will be, $(x-s)^{p-n-1} x$, $(x-s)$ whole to the power $n-2$, by factorial $n-2$, $(x-s)^{p-n} x$, multiplied with $(x-s)$ whole to the power $n-1$, by factorial $n-1$.

And we can write this entire expression into a compact form, using the summation notation, that is $\sum_{r=1}^n (x-s)^{r-1} x$, divided by, factorial $r-1$, multiplied with $p^r x$. So, if we start substituting r equal to 1, 2, 3, up to n . So, you will be having this entire expression. So that means, a general n th order linear differential equation can be converted into volterra integral equation of second kind by this method.

Now, the most crucial question is that, in one method, we have obtained the differential equation, in terms of the unknown function y , that is the first approach, and in the second approach we obtained the integral equation, in terms of the unknown function u , where u is the n th derivative of y . So, what is the relation between these 3, that is the given ordinary differential equation, integral equation in terms of the unknown variable involved with the ordinary differential equation and integral equation in terms of the unknown function, which we are introducing in terms of the formula $\frac{d^n y}{dx^n} = u(x)$.

Answer to this question is that, if $\phi(x)$ is a solution of the given ordinary differential equation, then u can verify, $\phi(x)$ will be solution of the integral equation what we have written in terms of y and n th derivative of this $\phi(x)$, will be solution of the integral equation what we have written in terms of u .

(Refer Slide Time: 51:03)

Ex. $\frac{d^2y}{dx^2} - y = x, \quad y(0) = 2, \quad y'(0) = 1$

$\frac{dy}{dx} = 1 + \int_0^x y(s) ds + \frac{x^2}{2}$

$y(x) = 2 + x + \frac{x^2}{6} + \int_0^x (x-s)y(s) ds \dots (i)$

$\frac{d^2y}{dx^2} = u(x) \Rightarrow \frac{dy}{dx} = 1 + \int_0^x u(s) ds$

$y = 2 + x + \int_0^x (x-s)u(s) ds$

$u(x) = 2 + 2x + \int_0^x (x-s)u(s) ds \dots (ii)$

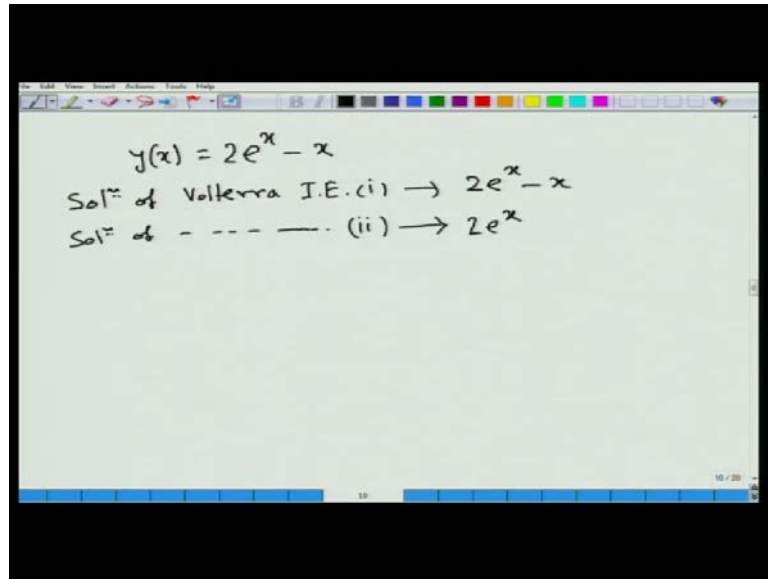

So, just have a quick look at this example, then you can clearly understand this idea. Consider this equation $\frac{d^2y}{dx^2} - y = x$, this is equal to x with the given conditions $y(0) = 2$ and $y'(0) = 1$.

So, using the first approach integrating this equation, you can write, $\frac{dy}{dx} = 1 + \int_0^x y(s) ds + \frac{x^2}{2}$, this 1 is coming from $y'(0) = 1$ and further integrating, you can find $y(x)$, this is equal to $2 + x + \frac{x^2}{6} + \int_0^x (x-s)y(s) ds$ and after using the replacement formula you'll be having $\int_0^x (x-s)y(s) ds$.

So, this is integral equation in terms of unknown function y . But if you use this notation $\frac{d^2y}{dx^2} = u(x)$, then from here, integrating from 0 to x , we can find $\frac{dy}{dx} = 1 + \int_0^x u(s) ds$ and again by integrating this expression, we can find $y = 2 + x + \int_0^x (x-s)u(s) ds$.

So, $\frac{d^2y}{dx^2} = u(x)$ is this 1. So, clearly from the given equation you can understand the required integral equation is $u(x) = y + x$. So that means, $2 + 2x + \int_0^x (x-s)u(s) ds$. So, call it as 1 and call it as 2. So, this is the integral equation in terms of the unknown function y and this is the integral equation in terms of the $u(x)$ where u is the second derivative of y .

(Refer Slide Time: 54:17)

$y(x) = 2e^x - x$
Soln of Volterra I.E. (i) $\rightarrow 2e^x - x$
Soln of - - - - (ii) $\rightarrow 2e^x$

And for the given ordinary differential equation, if you solve it then you can find, solution will be $y(x)$ equal to, $2e^x - x$. And therefore, solution of Volterra integral equation, in short we can write this I.E. 1 is $2e^x - x$ and solution of the Volterra integral equation 2, that is in terms of u what we have written that will be the second derivative of this function, that is $2e^x$. You can verify these are the solutions of these 2 problems.

So, this lecture we can stop at here. Just for a quick recapitulation that we have started with a second order ordinary differential equation, initial value problem where $p(x)$, $q(x)$, $r(x)$ is given, then using the generalized replacement formula and integrating the given equation both side twice, we obtained the general format for the integral equation in terms of y . This is a Volterra integral equation of second kind where $f(x)$ given by this formula and kernel is given by this one.

Then we have considered one example where $p(x)$ is $-\sin x$, $q(x)$ is e^x and right hand side function is x , and this technique can be adopted for third or fourth order equation, but of course, it is not possible to extend this idea, that, it will be little bit difficult to arrange these terms appearing after integration to write down the Volterra integral equation in terms of for the n th order ordinary differential equation. For those case we have to assume $\frac{d^n y}{dx^n} = u(x)$, and then using the successive steps you can find $n-1$ th derivative of y in terms of u , $n-2$ th derivative of y in terms

of u and in general n minus k derivative of y in terms of u ; finally, you will be arriving at this integral equation.

And then I have explained here the relation between the 2 methods; that means, solution of the original differential equation will be solution of the integral equation, if it is written in terms of the unknown function involved with the differential equation, and it is n th derivative, in this case we are considering second order differential equation. So, second order derivative of solution of the given equation will be solution of the volterra integral equation, written in terms of u . So, I stop for this lecture, at this point. Thank you.
