

Calculus of Variations and Integral Equation

Prof. Malay Banerjee

Department of Mathematics and Statistics

Indian Institute of Technology, Kanpur

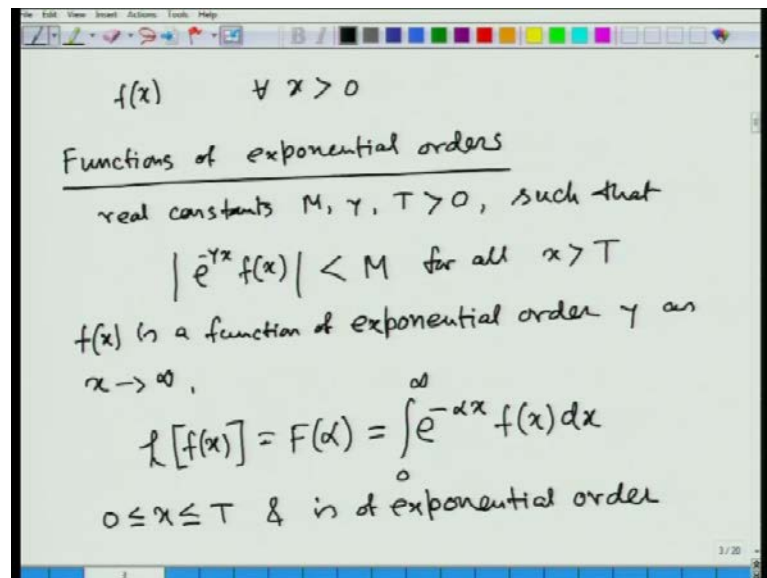

Module No. # 01

Lecture No. # 25

Welcome viewers to the 5th lecture of series of NPTEL lectures on Integral Equations. In the last lecture, we have discussed about the successive approximation method for solving, volterra integral equation of second kind.

Now, in today's lecture, we are going to discuss about two different techniques of solving volterra integral equation of first kind; and one method is Laplace transform method and second one is the series solution method. So, just for a quick recapitulation I start with the definition of Laplace transform, because we have to be specific about the notations we are going to use to solve the volterra integral equation of the first kind.

(Refer Slide Time: 01:14)

So, suppose $f(x)$ is a function, which is defined for all x greater than 0 and this function is of exponential order.

Now, before going to the definition of Laplace transform we try to understand, what is the meaning of functions of exponential order? This function $f(x)$ which is defined for all x greater than 0, now if there exist; real constants capital M , γ and T ; these are all greater than 0 such that, the function $f(x)$ when multiplied with e to the power minus γx , then its modulus is less than M for all x greater than capital T ; $f(x)$ is a function, which is defined for all x greater than 0, there exist three positive constants; one is M , second is γ , third is capital T ; such that, e to the power minus γx $f(x)$ is modulus is less than M for all x greater than equal to T .

If this happens then, we can say $f(x)$ is a function of exponential order **is a function of exponential order** and order of this given by γ as x tends to infinity or briefly we can say, this function is of exponential order. Actually, if a real valued function $f(x)$ for x greater than 0, if satisfies the exponential order criteria, then only its Laplace transform exist. And Laplace transform of this function $f(x)$ is denoted by L of $f(x)$. And oftenly, we denote these by $F(\alpha)$ and is defined by integral 0 to infinity e to the power minus αx $f(x) dx$, where α is a positive real constant.

Now, convergence of these integral depends upon the exponential order of the function. And actually, if this function $f(x)$ is sectionally continuous over the interval 0 less than equal to x less than equal to T and is of exponential order **and is of exponential order** then, this Laplace transform exist.

Now, once we use this Laplace transform to convert $f(x)$ to $F(\alpha)$; that means, we are relating this function of x to a real variable function that is constant of parameter α then of course, using the inverse Laplace transform we can get back this function $f(x)$ from, where we have obtained this $F(\alpha)$.

Now, most of the time we use the **(())** of Laplace transform table that is $F(\alpha)$ and $f(x)$ capital $F(\alpha)$ and $f(x)$ such that, when we considered the inverse Laplace transform of $F(\alpha)$ will be get back the function, $f(x)$.

(Refer Slide Time: 05:32)

$\mathcal{L}^{-1}[F(\alpha)] = f(x) \iff \mathcal{L}[f(x)] = F(\alpha)$
Convolution of two functions
 $f_1(x), f_2(x) \quad \mathcal{L}[f_1(x)] = F_1(\alpha)$
 $\mathcal{L}[f_2(x)] = F_2(\alpha)$
 $f_1 * f_2 = \int_0^x f_1(x-s) f_2(s) ds$
 $\mathcal{L}[f_1 * f_2] = \mathcal{L}[f_1(x)] \mathcal{L}[f_2(x)] = F_1(\alpha) F_2(\alpha)$
 $\mathcal{L}^{-1}[F_1(\alpha) F_2(\alpha)] = f_1 * f_2 = \int_0^x f_1(x-s) f_2(s) ds$

And according to the notation we use $\mathcal{L}^{-1} F(\alpha)$ that is equal to $f(x)$. So, this actually implies an implied by, if $\mathcal{L}[f(x)] = F(\alpha)$ then, $\mathcal{L}^{-1} F(\alpha)$ this is equal to $f(x)$. Now, we are going to use this particular Laplace transform in order to solve, Volterra integral equation of some special type and before going to that, I just like to recall another idea that is convolution of two functions **convolution of two functions**.

Let, $f_1(x)$ and $f_2(x)$; these are two real valued functions, defined for all x greater than 0 and both of them satisfies the criteria for exponential order. And the Laplace transforms are denoted by $\mathcal{L}[f_1(x)]$ this is equal to say, $F_1(\alpha)$ and $\mathcal{L}[f_2(x)]$ this is equal to $F_2(\alpha)$, these are the Laplace transform of $f_1(x)$ and $f_2(x)$.

Now, convolution of these two functions is denoted by $f_1 * f_2$ and defined by integral 0 to x $f_1(x-s) f_2(s) ds$, this is actually called convolution of two functions; $f_1(x)$ and $f_2(x)$, which is denoted by $f_1 * f_2$. You have to keep in mind, this convolution properties actually commodity, we can easily prove $f_1 * f_2$ is equal to $f_2 * f_1$ just by changing the variable, if we substitute $x-s$ equal to u , you can easily prove, this is equal to 0 to x integral $f_2(x-s) f_1(s) ds$.

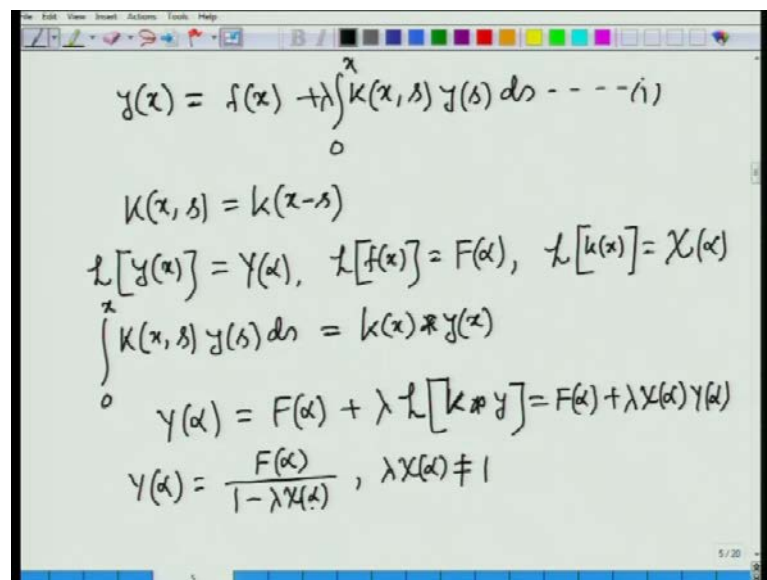

Now, interesting point is that, if we consider the Laplace transform of the convolution of these two functions; $f_1 * f_2$ then, it will give us the product of the Laplace transform of the functions, $\mathcal{L}[f_1(x)]$ multiplied by $\mathcal{L}[f_2(x)]$.

So, that means this is going to be $F_1(\alpha)$ multiplied by $F_2(\alpha)$. And most important part is that, if we have a function of α ; which can be expressed as product of two functions of α like $F_1(\alpha)$ and $F_2(\alpha)$ such that, from the table we know what are the functions for which $F_1(\alpha)$ and $F_2(\alpha)$ are the Laplace transform then, inverse Laplace transform of $F_1(\alpha)$ and $F_2(\alpha)$ will be the convolution of two functions; f_1 and f_2 .

So, that means $L^{-1} F_1(\alpha) \text{ multiplied by } F_2(\alpha)$, this is equal to $f_1 \star f_2$, so that is equal to $\int_0^x f_1(x-s) f_2(s) ds$, this is actually formula related with convolution of two functions and the Laplace transform.

Now, we are going to use these Laplace transform method in order to solve Volterra equation of second kind, but of course, for those Volterra equation of second kind, if lower limit is starting from 0; that means, instead of a ; if we have 0 and the kernel of the function is actually a function of difference of two variables that is $x-s$, then only we can apply this Laplace transform method.

(Refer Slide Time: 10:04)

The image shows a handwritten derivation on a digital whiteboard. The equations are as follows:

$$y(x) = f(x) + \lambda \int_0^x K(x,s) y(s) ds \quad \dots (1)$$

$$K(x,s) = k(x-s)$$

$$\mathcal{L}[y(x)] = Y(\alpha), \quad \mathcal{L}[f(x)] = F(\alpha), \quad \mathcal{L}[k(x)] = X(\alpha)$$

$$\int_0^x K(x,s) y(s) ds = k(x) \star y(x)$$

$$Y(\alpha) = F(\alpha) + \lambda \mathcal{L}[k \star y] = F(\alpha) + \lambda X(\alpha) Y(\alpha)$$

$$Y(\alpha) = \frac{F(\alpha)}{1 - \lambda X(\alpha)}, \quad \lambda X(\alpha) \neq 1$$

So, to be specific in terms of mathematical notations this is your given integral equation, $y(x)$ equal to $f(x)$ plus λ integral 0 to x $K(x,s) y(s) ds$. So, first criteria is lower limits should be equal to 0. Now, if capital $K(x)$ this is actually a function of small k of $x-s$, if this condition is satisfied by the kernel of the function, then only we can apply the Laplace transform method.

So, in this case you have to keep in mind, the applicability of this technique to find out the solution of the integral equation depends upon the lower limit whether it is 0 or not number 1. And secondly, kernel is of actually particular type k of x minus s and if this condition is satisfied then, first I described here how to proceed to find out the solution of the problem.

Suppose, Laplace transform of $y(x)$ this will be denoted by a capital Y of α as usual Laplace transform of $f(x)$ is denoted by capital F of α and Laplace transform of small $k(x)$ this will be denoted by χ of α , this is the notations. And actually you can try to understand that, whenever $K(x, s)$ is a function of the form $k(x - s)$ then, $\int_0^x K(x, s) y(s) ds$ this is nothing but, the convolution of the function small $k(x)$ and the unknown function; $y(s)$. So that means, specifically we can write if $K(x, s)$ satisfies this criteria then, $\int_0^x K(x, s) y(s) ds$, this is actually called to convolution of $k(x) \star y(x)$.

So, then we can take Laplace transform of the given integral equation. So, taking Laplace transform of this equation, call it 1; we can get $Y(\alpha)$ is equal to $F(\alpha)$ plus λ times Laplace transform of convolution of $k \star y$, this is small k keep in mind not capital K and this is equal to actually $F(\alpha)$ plus λ times $\chi(\alpha)$ multiplied by $Y(\alpha)$. So, solving for $Y(\alpha)$ we can find $Y(\alpha)$ this is equal to $F(\alpha)$ divided by $1 - \lambda \chi(\alpha)$ with the hypothesis that, $\lambda \chi(\alpha)$ this is not equal to 1.

So, once we have this result that is $Y(\alpha)$ is equal to $F(\alpha)$ by $1 - \lambda \chi(\alpha)$ then, we can solve it by using **inverse transform** inverse Laplace transformation method to get.

(Refer Slide Time: 14:04)

The image shows a digital whiteboard with handwritten mathematical derivations. At the top, the general formula is given: $y(x) = \mathcal{L}^{-1}[\mathcal{Y}(\alpha)] = \mathcal{L}^{-1}\left[\frac{F(\alpha)}{1 - \lambda \chi(\alpha)}\right]$. Below this, an example is worked out. The integral equation is $y(x) = x - \int_0^x (x-s)y(s)ds$. The kernel is identified as $k(x,s) = (x-s)$ and $k(x) = x$. The Laplace transform of x is $\frac{1}{\alpha^2}$. The transformed equation is $\mathcal{Y}(\alpha) = \frac{1}{\alpha^2} - \frac{1}{\alpha^2} \mathcal{Y}(\alpha)$, which simplifies to $\mathcal{Y}(\alpha) = \frac{1}{1+\alpha^2}$. Finally, the inverse Laplace transform is taken to find $y(x) = \sin x$. To the right of the main derivation, two known Laplace transform pairs are listed: $\mathcal{L}[x] = \frac{1}{\alpha^2}$ and $\mathcal{L}[\sin x] = \frac{1}{1+\alpha^2}$, with the corresponding inverse transform $\mathcal{L}^{-1}\left[\frac{1}{1+\alpha^2}\right] = \sin x$.

$y(x)$ is equal to \mathcal{L}^{-1} of $\mathcal{Y}(\alpha)$ and that is equal to inverse Laplace transform of $F(\alpha)$ divided by $1 - \lambda \chi(\alpha)$. So, once we are able to find out inverse Laplace transform of this algebraic expression in terms of α then, actually we can find the solution of the given problem as $y(x)$.

Now, we look at some illustrative example to understand this method. You can recall that, these problem we have solved earlier by using other technique, that is $y(x)$ is equal to x minus integral 0 to x of $x - s$ $y(s) ds$.

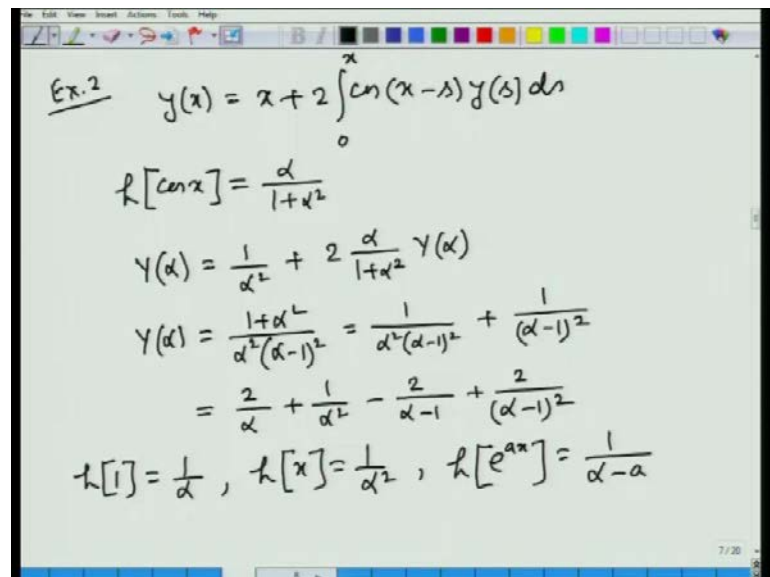

So, clearly you can understand that $K(x, s)$ is actually $x - s$. So, if we write in terms of small $k(x)$, so then small $k(x)$ is nothing but, x . And here, from the structure of the equation $f(x)$ is equal to x , $k(x)$ equal to x . So, we need only the knowledge about the Laplace transform of x and that is nothing but, $1/\alpha^2$.

So, using these result Laplace transform of x equal to $1/\alpha^2$, if we take the Laplace transform the given integral equation then, we can find $\mathcal{Y}(\alpha)$; this is equal to $1/\alpha^2$ minus $1/\alpha^2$ multiplied with $\mathcal{Y}(\alpha)$, this is the result. Actually this is coming from the concept that Laplace transform of integral 0 to x of $x - s$ $y(s) ds$ means; we are taking the Laplace transform of convolution of two functions; x and $y(x)$.

Now, Laplace transform of x is $1/\alpha^2$, Laplace transform of $y(x)$ we assumed to denote it by $Y(\alpha)$ then, Laplace transform the integral 0 to x $x \cos(x-s)y(s) ds$, these expression results in $1/\alpha^2 Y(\alpha)$.

So, solving for $Y(\alpha)$ we can find $Y(\alpha)$, this is equal to $1/\alpha^2$ and from the table we can find L of $\sin x$; that is Laplace transform of $\sin x$ is equal to $1/(1+\alpha^2)$ and hence, $L^{-1} 1/(1+\alpha^2)$ that is equal to $\sin x$. And hence, taking inverse Laplace transform of $Y(\alpha)$ we can find, $y(x)$ this is equal to $\sin x$. This is actually solution of the given integral equation that is first example.

(Refer Slide Time: 17:26)

The image shows a digital whiteboard with handwritten mathematical work. At the top, the integral equation is written: $y(x) = x + 2 \int_0^x \cos(x-s)y(s) ds$. Below this, the Laplace transform of $\cos x$ is given as $\frac{\alpha}{1+\alpha^2}$. Then, the Laplace transform of the equation is derived: $Y(\alpha) = \frac{1}{\alpha^2} + 2 \frac{\alpha}{1+\alpha^2} Y(\alpha)$. This is rearranged to $Y(\alpha) = \frac{1+\alpha^2}{\alpha^2(\alpha-1)^2} = \frac{1}{\alpha^2(\alpha-1)^2} + \frac{1}{(\alpha-1)^2}$. Further partial fraction decomposition is shown: $= \frac{2}{\alpha} + \frac{1}{\alpha^2} - \frac{2}{\alpha-1} + \frac{2}{(\alpha-1)^2}$. Finally, the inverse Laplace transforms are listed: $L^{-1}[1/\alpha] = 1$, $L^{-1}[1/\alpha^2] = x$, and $L^{-1}[1/(\alpha-a)] = e^{ax}$.

Now, we consider one more example, example 2 I am going to consider this example for the reason, that here in order to apply inverse Laplace transform; we have to utilize the first shifting property of inverse Laplace transform. So the first of all, we write the problem; problem is $y(x)$ equal to x plus 2 integral 0 to x cosine of x minus s $y(s) ds$.

Now, already I have mentioned that Laplace transforms of x is $1/\alpha^2$. And here, I can mention Laplace transform of cosine x , this is equal to $\alpha/(1+\alpha^2)$, this is the Laplace transform of cosine x ; this is needed because, here 0 to x cosine x minus s $y(s) ds$ is again convolution of two functions, that is cosine x and $y(x)$.

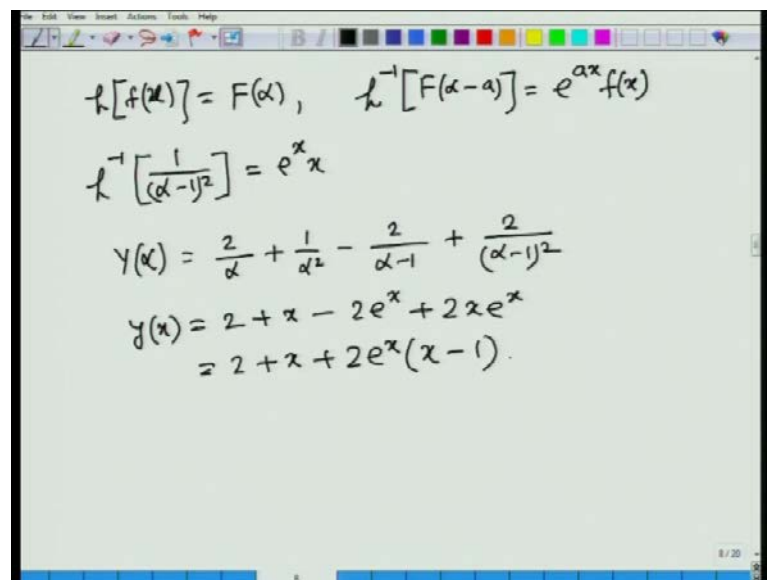

So, taking Laplace transform of the given integral equation, we can write $Y(\alpha)$ that is equal to $1/\alpha^2$ plus $2 \alpha/(1+\alpha^2)$ this multiplied with Y

alpha. And transferring this particular term on to the left and after rearranging, we can find $Y(\alpha)$ this is equal to $1 + \alpha^2$ divided by $\alpha^2(\alpha - 1)^2$, and we can rearrange this term first into the form that is 1 by α^2 times $\alpha - 1$ whole square plus 1 by $\alpha - 1$ whole square.

And using the method of partial fractions, we can write this is equal to after some algebraic calculation, this will be equal to $\frac{2}{\alpha} + \frac{1}{\alpha^2} - \frac{2}{\alpha - 1} + \frac{2}{(\alpha - 1)^2}$; so, this will be the expressions.

Now, we need this results that is L of 1 equal to 1 by α . Actually, inverse Laplace transform of 1 by α will be then 1 . Already we know the result that is Laplace transform of x that is equal to 1 by α^2 . So, inverse Laplace transform of 1 by α^2 will be x . And thirdly, Laplace transform of e to the power $a x$ this is equal to 1 by $\alpha - a$; so, that means inverse Laplace transform of 1 by $\alpha - 1$ is going to be e to the power x . And now, we have to be careful for the inverse Laplace transform for 1 by $\alpha - 1$ whole square.

(Refer Slide Time: 21:00)

The image shows a digital whiteboard with handwritten mathematical derivations. At the top, there is a toolbar with various drawing and editing tools. The main content consists of several lines of handwritten text and equations:

$$L[f(x)] = F(\alpha), \quad L^{-1}[F(\alpha - a)] = e^{ax} f(x)$$

$$L^{-1}\left[\frac{1}{(\alpha - 1)^2}\right] = e^x x$$

$$Y(\alpha) = \frac{2}{\alpha} + \frac{1}{\alpha^2} - \frac{2}{\alpha - 1} + \frac{2}{(\alpha - 1)^2}$$

$$y(x) = 2 + x - 2e^x + 2xe^x$$

$$= 2 + x + 2e^x(x - 1)$$

At the bottom right corner of the whiteboard, there is a small status bar showing "8 / 20".

And here actually we need to apply the first shifting property of inverse Laplace transform; it states that, if L of $f(x)$ is equal to $F(\alpha)$, then inverse Laplace transform of $F(\alpha - a)$, this is equal to e to the power $a x$ multiplied by $f(x)$. So, actually we apply this result in order to find out this inverse Laplace transform of 1 by $\alpha - 1$ whole square.

So, if we consider, if α equal to 1 by α square, then 1 by α minus 1 whole square is coming out to be f of α minus 1. So, with α equal to 1 and then, using this first shifting property; we can write this is equal to e to the power x into x , because this e to the power x coming from the part e to the power αx and this x is stands for a $f x$ because, this 1 by α square is actually Laplace transform of x . So, L^{-1} 1 by α minus 1 whole square is equal to $x e$ to the power x .

So, therefore, from $Y(\alpha)$ is equal to 2 by α plus 1 by α square minus 2 by α minus 1 plus 2 by α minus 1 whole square. If we take the inverse Laplace transform, then we will be having $y(x)$ this is equal to 2 inverse Laplace transform 1 by α is 1 plus x here minus $2 e$ to the power x plus $2 x e$ to the power x . So, answer will be required answer is 2 plus x plus $2 e$ to the power x into x minus 1 . So, this is the solution for the given volterra integral equation of the first kind.

Next, we considered one more example; this is little bit interesting only for the reason that, when we solve this equation then, you can find that solution of the given equation is completely related with the non homogeneous part of the integral equation involved with the given problem.

(Refer Slide Time: 23:32)

Ex-3

$$y(x) = f(x) + 3 \int_0^x e^{x-s} y(s) ds$$

$$Y(\alpha) = F(\alpha) + \frac{3}{\alpha-1} Y(\alpha)$$

$$Y(\alpha) = F(\alpha) \frac{\alpha-1}{\alpha-4} = F(\alpha) + 3 F(\alpha) \frac{1}{\alpha-4}$$

$$y(x) = \mathcal{L}^{-1} \left[F(\alpha) + 3 F(\alpha) \frac{1}{\alpha-4} \right]$$

$$= f(x) + 3 e^{4x} * f(x)$$

$$= f(x) + 3 \int_0^x e^{4(x-s)} f(s) ds$$

This example 3; it states that, $y(x)$ is equal to $f(x)$ plus 3 integral 0 to x e to the power x minus s $y(s) ds$. So, here e to the power x minus s is $(())$, so that means first function $f(x)$ is e to the power x and second function is $y(s)$. And already we have noticed that,

Laplace transform of e^{ax} is equal to $\frac{1}{s-a}$ (Refer Slide Time: 24:10). So, therefore, Laplace transform of e^{ax} is going to be $\frac{1}{s-a}$.

So here, if we take the Laplace transform of both the sides, this is actually convolution of e^{4x} and $y(x)$. So, taking Laplace transform we can find $Y(s)$, this is equal to $F(s) + 3$ divided by $s-4$ this multiplied with $Y(s)$ this one.

Now, if we simplify it, then we can find $Y(s)$; this is equal to $F(s)$ times $s-4$ plus 3 divided by $s-4$ and writing the numerator into the form $s-4$ plus 3 we can find from here, that is $F(s)$ plus 3 multiplied with $\frac{1}{s-4}$. So now, $F(s)$ comes into this part.

And from here, if we take the inverse Laplace transform of the both sides, then $y(x)$ is equal to inverse Laplace transform of $F(s) + 3$ multiplied with $\frac{1}{s-4}$. So, this is equal to $f(x)$ because, we have denoted the Laplace transform of $f(x)$ by capital $F(s)$. So, inverse Laplace transform of capital $F(s)$ will be, $f(x)$ plus 3 convolution of e^{4x} with $f(x)$, this is actually the convolution of this two functions.

So, writing the formula for convolution of two functions; we can find, this is equal to $f(x)$ plus $3 \int_0^x e^{4(x-s)} f(s) ds$. So, this problem is little bit interesting only **from that** for the reason that, given integral equation is $y(x)$ equal to this one.

Now, once this $f(x)$ is known **this $f(x)$ is known**, so result of the integral equation is completely depends upon this integral. So, once $f(x)$ is known, so substituting $f(x)$ here we can evaluate this integral and then, this will gives as the desired result for the given problem **we can evaluate this integral and then this will gives us the desired result for the given problem.**

(Refer Slide Time: 27:09)

Series solution method.

$$y(x) = f(x) + \lambda \int_0^x K(x,s) y(s) ds$$

$$y(x) = \sum_{n=0}^{\infty} C_n x^n$$

$$\sum_{n=0}^{\infty} C_n x^n = f(x) + \lambda \int_0^x K(x,s) \left(\sum_{n=0}^{\infty} C_n s^n \right) ds$$

$$\Rightarrow C_0 + C_1 x + C_2 x^2 + \dots = f(x) + \lambda C_0 \int_0^x K(x,s) ds + \lambda C_1 \int_0^x K(x,s) s ds + \lambda C_2 \int_0^x K(x,s) s^2 ds + \dots$$

Next, we consider the series solution method (No audio from 27:10 to 27:19); series solution method for volterra integral equation of the second kind. Again in this case, we restrict ourselves problems of the type $y(x)$ equal to $f(x)$ plus λ times integral 0 to x $K(x,s) y(s) ds$.

So, here only lower limit 0, this is required and there is no restriction for $y(x)$; that means, no particular format for this kernel is required as we have seen that, in case of applying Laplace transform is need to be $K(x,s)$ is a function of $x - s$. But, at a later stage I will make some remark that in which cases we can think about solution of the integral equation **into the** with the help of series solution method. So, the point is that, we are assuming that solution of this equation can be expressed as a power series around x equal to 0.

So, we are assuming solution in the form, $y(x)$ is equal to $\sum_{n=0}^{\infty} C_n x^n$, this is our targeted form of the solution, so that means if we are going to solve this equation by series solution method then, we have to substitute this expression into the given equation then, we can integrate these $K(x,s)$ multiplied by the series it will be actually converted into term by term integration and then, using the Taylor series expansion of effects we have to solve for C_0, C_1, C_2 and so on.

And actually we have to derive some recurrence formula from where once we know the values of some initial C_0, C_1, C_2 ; using the recurrence formula will be able to

calculate all C_n 's. Now, the method is, if you substitute the series into this given problem. So, it is equal to n running from 0 to infinity $C_n x$ to the power n , this is equal to $f(x)$ plus λ times integral 0 to x $K(x, s)$ $\sum_{n=0}^{\infty} C_n s$ to the power n , this is expression for $y(s)$.

And this actually implies will be having C_0 plus $C_1 x$ plus $C_2 x^2$ plus dot dot, this is equal to $f(x)$ plus λ times C_0 integral 0 to x $K(x, s) ds$ plus λ times C_1 integral 0 to x $K(x, s) s ds$ plus λ times C_2 integral 0 to x $K(x, s) s^2 ds$ plus dot dot dot.

Now, using the continuity of this kernel $K(x, s)$ over the square domain 0 to say some β cross 0 to β we can find that, the summation and integral sign can be interchanged. And then, after expanding will be having this type of infinite series consist of summation of these integrals.

And after expressing effects in terms of a Taylor series, we can get this expression which is valid for all x then, **been** collecting the coefficients of equal power suffix; we can find a system of equation. And solving the system of the equation once you find out C_0 , C_1 , and C_2 and so on, then we can have the solution for the given integral equation. So, in order to understand this method we consider two examples.

(Refer Slide Time: 31:53)

Ex.1 $y(x) = x - \int_0^x (x-s)y(s) ds$

$y(x) = \sum_{n=0}^{\infty} C_n x^n$

$C_0 + C_1 x + C_2 x^2 + \dots = x - C_0 \int_0^x (x-s) ds - C_1 \int_0^x (x-s)s ds - \dots - C_n \int_0^x (x-s)s^n ds - \dots$

$= x - C_0 \left(x \cdot x - \frac{x^2}{2} \right) - C_1 \left(x \frac{x^2}{2} - \frac{x^3}{3} \right) - \dots - C_n \left(x \frac{x^{n+1}}{n+1} - \frac{x^{n+2}}{n+2} \right) - \dots$

$= x - C_0 \frac{x^2}{2} - C_1 \frac{x^3}{2 \cdot 3} - \dots - C_n \frac{x^{n+2}}{(n+1)(n+2)} - \dots$

First example is $y'' = x$, this is equal to x minus integral 0 to x of x minus $s y' ds$. So, of course, **the** this equation we just solve with help of Laplace transform method and just to verify that, whether we are getting same solution or not; we going to apply here the series solution method.

Now, you can see that, if we use series solution method here, so substituting the series that is $\sum_{n=0}^{\infty} C_n s^n$ to the power n ; we have to integrate the integrals of the form 0 to x of x minus $s ds$ then, 0 to x of x minus s multiplied by $s ds$. So, in general, that means 0 to x of x minus s multiplied by s to the power **$((n))$** .

So, for each n ranging from 0 to infinity will be integrating the integrand that is x into s to the power n minus s to the power $n+1$, it is very easy to integrate. So, this gives us some sort of indication that, although we can apply the Laplace transforms method to solve this equation. And then, we can going to apply this series solution method whenever this integrand is easy to handle or it will be easy to integrate this integrand coming out after substituting $\sum C_n s^n$ to the power n .

So, here substituting this series $y'' = x$ is equal to $\sum_{n=0}^{\infty} C_n x$ to the power n , we can find on the left hand side; C_0 plus $C_1 x$ plus $C_2 x^2$ plus dot dot, these are the terms. And here we do not need to think about further, because $f(x)$ is simply x and then, minus C_0 integral 0 to x of x minus $s ds$ minus C_1 integral 0 to x of x minus s **$s ds$** minus dot dot, general term is C_n integral 0 to x of x minus s multiplied with s to the power $n ds$ minus dot dot, here this should not be plus whether it will be minus here (Refer Slide Time: 34:42).

After integration we can find this is equal to x minus $C_0 x$ into x minus x^2 by 2 minus C_1 this is x into s , so that means x into x^2 by 2 minus **$((n))$** , so that is x^3 by 3 minus dot dot; in this way general term will be, minus $C_n x$ into x to the power n plus 1 by factorial $n+1$ minus x to the power $n+2$ divided by $n+2$ minus dot dot. So, this is actually the general term, what will be getting after integration.

So, this is actually equal to x minus $C_0 x^2$ by 2 minus $C_1 x^3$ by 2 into 3; and here as a general term will be having minus $C_n x$ to the power $n+2$ divided by $n+2$ multiplied with $n+2$ **I am sorry** here it will be $n+2$ (Refer Slide Time: 36:15).

So, term after C_1 it is clearly it will be minus $C_2 x$ to the power 4 divided by 3 into 4 and so on minus dot dot. So, if we equate first few terms on the left hand side; we have C_0 , there is no constant term on the right hand side.

(Refer Slide Time: 36:42)

The image shows a digital whiteboard with handwritten mathematical work. On the left side, the coefficients are calculated as follows:

$$C_0 = 0$$

$$C_1 = 1$$

$$C_2 = -\frac{C_0}{2} \Rightarrow C_2 = 0$$

$$C_3 = -\frac{C_1}{2 \cdot 3} = -\frac{1}{2 \cdot 3}$$

$$C_{n+2} = -\frac{C_n}{(n+1)(n+2)}$$

$$C_4 = C_6 = C_8 = \dots = 0$$

$$C_5 = -\frac{C_3}{4 \cdot 5} = \frac{1}{15}$$

$$C_7 = -\frac{C_5}{6 \cdot 7} = -\frac{1}{17}$$

On the right side, the function $y(x)$ is expressed as a series:

$$y(x) = x - \frac{x^3}{13} + \frac{x^5}{15} - \frac{x^7}{17} + \dots$$

$$= \sin x$$

So, therefore, C_0 this is equal to 0. So, this result we are getting by equating constant term from both the sides. Next, if you look at the coefficient of x on the left hand side, coefficient of x is C_1 and on the right hand side coefficient of x is 1. So, therefore, equating the coefficient of x ; we can find C_1 this is equal to 1. Next, square term $C_2 x^2$ square this is equal to minus $C_0 x^2$ square by 2 (Refer Slide Time: 37:24). So, that means C_2 , this is equal to minus C_0 by 2 this implies, C_2 equal to 0, because C_0 equal to 0.

Similarly, if we equate the coefficient of cubic term here we have $C_3 x^3$ and on the right minus $C_1 x^3$ by 2 into 3 e. So, therefore, C_3 is equal to minus C_1 by 2 into 3. So, this is equal to minus 1 by 2 into 3. And recurrence formula can be obtain in this way; on the left hand side, coefficient of x to power n plus 2 is actually C_{n+2} . And here we have already observed that, coefficient of x to the power n plus 2 on the right hand side, is minus C_n divided by n plus 1 multiplied by n plus 2.

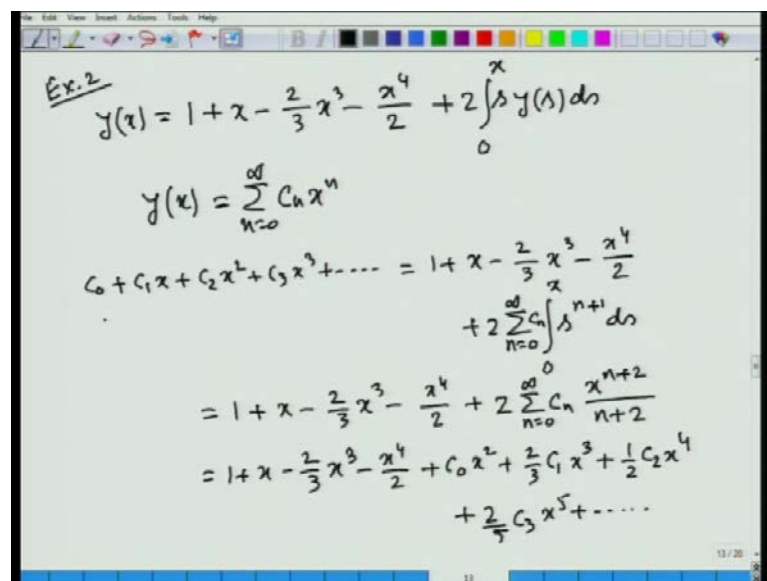

So, therefore, equating the coefficient of x to power n plus 2 from both sides, will be having minus C_n divided by n plus 1 into n plus 2. So, using this recurrence formula and the results; C_0 equal to 0, C_2 equal to 0, we can find C_4 equal to C_6 equal to C_8 , all these coefficients exactly equal to 0.

We have already obtained C_3 then, C_5 , this is going to be minus C_3 divided by 4 into 5. So, after substituting this expression minus 1 by 2 into 3 we can write, this is equal to 1 by factorial 5 then, C_7 will be minus C_5 divided by 6 into 7. So, this is equal to minus 1 by factorial 7 and so on.

So, if we substitute these expressions into the series that, we have assume, then we can find $y(x)$; this is equal to x minus x cube by factorial 3 plus x to the power 5 by factorial 5 minus x to the power 7 by factorial 7 plus dot dot. So, that means we are getting the MacLaurin's infinite series expansion for $\sin x$. So, therefore, by using the method of series solution; we are getting the solution $y(x)$ is equal to $\sin x$, for the given problem.

Last example that I am going to consider here, that is little bit interesting only for the reason that, although we are assuming a infinite series solution for the given problem, but after solving the problem; you can see that, the solution is actually a polynomial.

(Refer Slide Time: 40:42)

The image shows a digital whiteboard with handwritten mathematical work. At the top left, it is labeled 'Ex. 2'. The main equation is $y(x) = 1 + x - \frac{2}{3}x^3 - \frac{x^4}{2} + 2 \int_0^x y(s) ds$. Below this, the series form $y(x) = \sum_{n=0}^{\infty} C_n x^n$ is written. The next line shows the series expansion: $C_0 + C_1 x + C_2 x^2 + C_3 x^3 + \dots = 1 + x - \frac{2}{3}x^3 - \frac{x^4}{2} + 2 \sum_{n=0}^{\infty} C_n \int_0^x s^{n+1} ds$. This is then simplified to $= 1 + x - \frac{2}{3}x^3 - \frac{x^4}{2} + 2 \sum_{n=0}^{\infty} C_n \frac{x^{n+2}}{n+2}$. The final line shows the result of equating coefficients: $= 1 + x - \frac{2}{3}x^3 - \frac{x^4}{2} + C_0 x^2 + \frac{2}{3}C_1 x^3 + \frac{1}{2}C_2 x^4 + \frac{2}{5}C_3 x^5 + \dots$. The whiteboard interface includes a toolbar at the top and a status bar at the bottom showing '13 / 20'.

And the problem is, $y(x)$ this is equal to 1 plus x minus two-third x cube minus x to the power 4 by 2 plus 2 integral 0 to x $s y(s) ds$. Again, look at the kernel involved with this particular problem, it is only s here. So, that means if we use this particular series assumption about the existence of series solution that is 0 to infinity $C_n x$ to the power n .

So, after substitution the general term actually we need the integral of s to the power n plus 1. So, this is very easily easy to integrate and obtain the result into the closed form. So, most of the time will be adapting the series solution technique, whenever after multiplying s to power n by the kernel involve with the integral equation; it is easy to handle, that is the some sort of you can say, a suggestion where we can apply the series solution method.

Now, if we substitute this series into these given problem, $(())$ will be having C_0 plus $C_1 x$ plus $C_2 x^2$ plus $C_3 x^3$ plus dot dot; this is equal to $1 + x - \frac{2}{3} x^3 - \frac{x^4}{2} + 2 \sum_{n=0}^{\infty} \int_0^x s^{n+1} ds$.

So, after integration this is coming out to be $1 + x - \frac{2}{3} x^3 - \frac{x^4}{2} + 2 \sum_{n=0}^{\infty} \frac{x^{n+2}}{n+2}$, here I have missed the C_n term; this is C_n (Refer Slide Time: 43:16). So, that means we have this particular series.

Now, this problem is little bit interesting from two sides; number 1 upto x to the power 4 we have one sort of relations between these $(())$ and for x to the power $n+2$ by $n+2$ whenever $n+2$ is greater than 4, then will be having another set of relations.

So, first of all we have to find out first four constants; C_0, C_1 upto C_4 carefully because, on the right hand side; we have these expressions involve with the part $f(x)$ and rest of the the part does not interfere here. **So, that is no $f(x)$ and rest the part does not interfere here.** So, that means no turn from x will interfere with the series whenever the index is high and higher.

So, this is equal to $1 + x - \frac{2}{3} x^3 - \frac{x^4}{2} + 2 \sum_{n=0}^{\infty} \frac{x^{n+2}}{n+2}$ and if we substitute, n equal to 0 here; so, these series start it is giving contributions from x^2 square and onwards; for x^2 square will be having $C_0 x^2$ substituting n equal to 0, will be having x^2 square from here. Substituting, n equal to 1 will be having two-third $C_1 x^3$, this is the second term from the series then, plus half $C_2 x^4$, this is the term we get by substituting n equal to 2 plus rest of that term will be of the form $2/5 C_3 x^5$ and so on.

Now, if we just compare the constant terms from the both sides.

(Refer Slide Time: 45:24)

$$\begin{aligned}C_0 &= 1 \\C_1 &= 1 \\C_2 &= C_0 = 1 \\C_3 &= -\frac{2}{3} + \frac{2}{3}C_1 = 0 \\C_4 &= -\frac{1}{2} + \frac{C_2}{2} = 0 \\C_{n+2} &= 2 \frac{C_n}{n+2}, \quad n \geq 3 \\C_5 &= C_6 = C_7 = \dots = 0 \\y(x) &= 1 + x + x^2\end{aligned}$$

So, first of all we will be having C_0 this is equal to 1, because on the left hand side; it is C_0 and on the right hand side; we have only 1 here. Then, collecting the coefficient of x from both sides we can find on the left it is C_1 ; on the right, it is x only.

So, therefore, C_1 this is equal to 1. Next, we look at the coefficient of x square term. Here, it is C_2 and in this $f(x)$ part; there is no x square term and x square term is coming from these parts (Refer Slide Time: 45:59). So, that is C_0 . So, coefficient of x square on the right hand side, it is C_0 ; on the left hand side, it is C_2 . So, **he** equating we can find C_2 , this is equal to C_0 and already we have obtained C_0 equal to 1, so this C_2 coming out to be 1.

Next, we collect the coefficient of x cube on the left hand side; coefficient of x cube, this is equal to C_3 , on the right hand side; $f(x)$ part contains minus two-third x cube. So, minus two-third is coming from here and here will be having plus two-third C_1 . So, this is minus two-third plus two-third these multiplied by C_1 ; already we know the value of C_1 . So, after substituting the C_1 value will be having this is identically equal to 0.

Last but one, that is coefficient of x to the power 4, on the left hand side it is C_4 . So, from left hand side; will having C_4 and from the right hand side; this is minus half and plus C_2 by 2, here coefficient of x to the power 4 is C_2 by 2 (Refer Slide Time: 47:16).

So, this gives minus half plus C_2 divided by 2, we already have C_1 equal to 1. So, this is equal to 0. So, two consecutive terms C_3 and C_4 this is equal to 0. Now, on the rest of the terms; that is terms of the form x to the power 5 and higher, on the left hand side we will be having C_5 , C_6 and so on. These are the coefficients of x to the power 5 x to the power 6 and so on.

And on the right hand side; this is nothing but, $2 C_n$ divided by $n + 2$, this is the coefficient of x to the power $n + 2$. So, that means collecting the coefficient of x to the power $n + 2$ from the both sides in order to get the recurrence relation; we can write recurrence relation is coming out to be C_{n+2} , that is equal to $2 C_n$ divided by $n + 2$.

Now remember, these result is valid for n greater than or equal to 3 because, already we have equated the coefficient of constant term from both sides, coefficient of x from both sides upto coefficient of x to the power 4 from both sides. And these we have done only for the reason that, $f(x)$ part contains term upto the order x to the power 4.

So, from x to the power 5 and onwards; we can write the general recurrence formula. So, from the left we are getting the coefficient of x to the power $n + 2$ is simply C_{n+2} . And on the right hand side; coefficient of x to the power $n + 2$ is actually $2 C_n$ divided by $n + 2$.

Now, this result is valid for n greater than equal to 3. So, clearly from C_3 equal to 0 and C_4 equal to 0; you can find C_5 , C_6 ; which is equal to C_7 and onwards, all these coefficients are identically equal to 0; C_5 , C_6 , C_7 are all this quantity equal to 0.

Already we have C_3 , C_4 this is equal to 0. So, although we have assume an infinite series as a solution of the given problem, but we landed at a solution that is given by $1 + x + x^2$, there is no other terms involving higher powers of x . So, this is clearly a polynomial, which is a solution for the given problem.

And I hope you have experienced these type of situations will appear **it** in case of ordinary differential equations also. And this volterra integral equations is most of the time, we obtain it by converting the linear ordinary differential equations that is initial value problems converted to volterra integral equations. And therefore, in case of ordinary differential equation we have the experience that sometimes we are trying to

find a solution, which are assume to be an infinite series, but ultimately solutions are comes out to be a polynomial.

So, just for a quick recapitulation what we have done today. So, first of all we have defined what Laplace transforms for a function with exponential order is. And then, we have considered the convolution of two functions; $f_1(x)$ and $f_2(x)$. And Laplace transform of convolution of two functions; f_1 and f_2 is nothing but, the product of the Laplace transform of these two functions and these Laplace transform method can be solved sorry can be used to solve the volterra integral equation of first kind, whenever this kernel $K(x, s)$ is a special type that is it is a function of $x - s$ only.

And in the illustrative example, we have seen in one case; we have used $x - s$ as the kernel. So, therefore, $k(x)$ was equal to x . Secondly, $K(x, s)$ is cosine $x - s$. So, that means small $k(x)$ is nothing but, cosine x . And third problem that we have considered that, kernel $k(x - s)$ is actually e to the power $x - s$.

So, for those problems we can apply these Laplace transform method to solve it and we need the formula for inverse Laplace transform from any table of Laplace transform; we can get this result to find out the ultimate solution of the given problem. And then, we have considered the series solution means, where we are assuming solution into the form $y(x) = \sum_{n=0}^{\infty} C_n x^n$; after substituting this expression into the integral equation; we are having some recurrence relation equating the general form of the x to the power n term, most of the time we have used the coefficient of x to power $n + 2$ from the both sides.

And of course, you have to be careful about the Taylor series expansion for $f(x)$, fortunately the examples that I considered here those are having finite number of terms in the Taylor series expansion for $f(x)$. And in the last example we have observed that, these solution results in a polynomial rather than an infinite series. So, thank you for your attention.
