$$\frac{d}{dx} \left[p(x) \frac{dy}{dx} \right] + (q(x) + \lambda r(x)) y = g(x)$$
$$m_1 y(a) + m_2 y'(a) = 0 \quad a \leq x \leq b$$
$$m_3 y(b) + m_4 y'(b) = 0$$
$$y(x) = - \int_a^b G(x, s) g(s) ds$$
$$G(x, s) = \begin{cases} \frac{y_2(s) y_1(x)}{\alpha}, & a \leq s < x \leq b \\ \frac{y_1(s) y_2(x)}{\alpha}, & a \leq x < s \leq b \end{cases}$$
$$y_1(x), y_2(x) \quad \mathcal{L}y \equiv (py')' + (q + \lambda r)y = 0$$

In the last lecture we were discussing about the Greens function for linear boundary value problems, just for a quick recapitulation, you can recall we were dealt with $(())$ type boundary value problems, which are defined by $d dx$ of $px dy dx$ plus qx plus $\lambda rx yx$. This is equal to 0 for homogenous boundary value problem and this is equal to gx for non-homogenous boundary value problem with the separated boundary conditions $m_1 ya$ plus $m_2 y \dot{a}$. This is equal to 0 $m_3 yb$ plus $m_4 y \dot{b}$, this is equal to 0. This is called separated boundary conditions where $a \leq x \leq b$; p dash x q x and r x , these are all continuous over the interval a to b , λ is a parameter.

With these assumptions we arrived at the position, that solution of this equation can be written as $y(x)$, that is equal to minus integral a to b $G(x, s) g(s) ds$, but this capital $G(x, s)$ is the base function. And this particular greens function we defined, as well as, derived, as this is equal to $y_2(s) y_1(x)$ divided by α for $a \leq s \leq x < b$ and $y_1(x) y_2(s)$ divided by α , where $a \leq x < s \leq b$, where this $y_1(x)$ and $y_2(x)$, these two functions were the solution of the corresponding homogenous equation $L(y)$, that is equivalent to, in short if we can write, that is, $p y'' + q y' + \lambda r y = 0$. This was two linear independent solution of this equation.

(Refer Slide Time: 03:54)

The image shows a digital whiteboard with the following content:

$$m_3 y_1(b) + m_4 y_1'(b) = 0$$

$$m_1 y_2(a) + m_2 y_2'(a) = 0$$

Properties of Green's Function.

(i) $G(x, s)$ is symmetric for
 $G(x, s) = G(s, x)$

(ii) $G(x, s)$ satisfies the boundary conditions
 $y(a) = 0 = y(b) \quad y_1(b) = 0, \quad y_2(a) = 0$

$$G(x, s) = \begin{cases} \frac{y_2(s)y_1(x)}{\alpha}, & a \leq s < x \leq b \\ \frac{y_1(s)y_2(x)}{\alpha}, & a \leq x < s \leq b \end{cases}$$

And not only they are just linearly independent solution of this equation, there was another restriction based upon which we have constructed the Greens function. Those restrictions was, that y_1 satisfies the boundary conditions on the right hand, that is, $m_3 y_1(b) + m_4 y_1'(b)$, this is equal to 0 and $y_2(x)$, that satisfies the boundary conditions on the left. That means, $m_1 y_2(a) + m_2 y_2'(a)$, this is equal to 0. So, based upon this we have constructed our Greens function.

Now, in this particular formation 1.1.1, that means, $1/\alpha$ still remains undefined, that now we are going to define along with some discussion on properties of this Green's functions. So, now, let us look at the properties of Green's functions.

First of all you can easily verify, that $g(x, s)$ is symmetric, is a symmetric function of two variables x and s , that is, $G(x, s)$ is equal to $G(s, x)$. So, that means, interchanging the role of x and s you can easily verify, that this condition is satisfied. Secondly, the important properties is, that $G(x, s)$ this actually satisfies the boundary conditions; this satisfies the boundary conditions. And of course, you can verify, that $\Delta g(x, s)$ satisfies this type of $m_1 y_2 + m_2 y_2 \cdot a$, this is equal to 0.

Now, without any loss of generality if we simply assume the boundary conditions into this particular format, say $y_1 a$, this is equal to 0 equal to $y_2 b$. The simplest boundary condition corresponding to $m_1 y_1 + m_2 y_2 \cdot a = 0$ and $m_3 y_3 + m_4 y_4 \cdot b = 0$. So, that means, choosing m_2 and m_4 equal to 0 we can arrive at this type of boundary conditions. Now, with this a , that is, y_1 satisfies boundary conditions on the right implies $y_1 p$, this is equal to 0 and $y_2 x$ satisfies the boundary conditions on the left, means $y_2 a$, this is equal to 0.

Now, look at the definition for the Green's function. Green's function is $G(x, s)$, that is equal to here, $y_2 s y_1 x$ divided by α . This is defined for $a \leq s \leq x$ and $a \leq x \leq b$ and $y_1 x y_2 x$ divided by α , where $a \leq x \leq b$ and $a \leq s \leq b$.

(Refer Slide Time: 08:01)

The image shows a whiteboard with handwritten mathematical notes. At the top, there are two equations for boundary conditions: $G(b, s) = \frac{y_1(b) y_2(s)}{\alpha} = 0$ and $G(a, s) = \frac{y_2(a) y_1(s)}{\alpha} = 0$. Below these, there are two properties listed: (iii) $G(x, s)$ is continuous on $[a, b] \times [a, b]$ and (iv) Partial derivative of $G(x, s)$ has a jump discontinuity. The jump discontinuity is expressed as $\left. \frac{\partial G(x, s)}{\partial x} \right|_{x=s_+} - \left. \frac{\partial G(x, s)}{\partial x} \right|_{x=s_-} = -\frac{1}{p(s)}$, where $x > s$ and $x < s$ are indicated under the respective terms.

Now, look at this definition. In the first part x can be equated to b , so therefore, when you are substituting x equal to b in the Green's function, then G of (b, s) , that means, you

are substituting x equal to b and from this definition x equal to b is allowed for the, when $G(x, s)$ equal to $y_2 s y_1 x$ by α . So, this is, this will come out as $y_1 b y_2 s$ divided by α . And already we have mentioned, that $y_1 b$ equal to 0, so therefore, this is equal to 0.

Similarly, we can easily verify, that $G(a, s)$, that is equal to $y_2 a y_1 s$ divided by α , this is equal to 0. So, this, that means, the Green's function satisfies the boundary conditions on the left hand point and as well as the right hand point. And similarly, using the property, that $m_3 y_1 b$ plus $m_4 y_1 \cdot b$, you can verify, that they also satisfy the boundary condition, when boundary condition given in general point at this $G(x, s)$. This continues on this square domain (a, b) cross (a, b) and its partial derivative, this partial derivative has been jumped discontinuity along the line x equal to s and this is given by that partial derivative of $G(x, s)$ has a jump discontinuity, and it is defined as $\frac{\partial}{\partial x} G(x, s)$ and x equal to s plus. So, that means, we have to use the definition x greater than s minus $\frac{\partial}{\partial x} G(x, s)$ at x is equal to s minus. That means, we have to use x less than s , that is equal to minus 1 by $p(s)$ and from here we can easily find out what will be the value of α ? What expectation of α in terms of s ?

(Refer Slice Time: 10:59)

$$\frac{d^2 y}{dx^2} + A_1(x) \frac{dy}{dx} + A_2(x) y = G_1(x), \quad y(a) = 0 = y(b)$$

$$p(x) \frac{d^2 y}{dx^2} + p(x) A_2(x) \frac{dy}{dx} + p(x) A_2(x) y = p(x) G_1(x)$$

$$p(x) = e^{\int A_1(x) dx}$$

$$\frac{d}{dx} p(x) = A_1(x) e^{\int A_1(x) dx} = p(x) A_1(x)$$

$$\frac{d}{dx} \left[p(x) \frac{dy}{dx} \right] + q(x) y = g(x)$$

$$q(x) = p(x) A_2(x), \quad g(x) = p(x) G_1(x)$$

Now, before proceeding further I just want to make a remark here, that initially we started our discussion on this type of ordinary differential equation subjected to boundary conditions, that is, $\frac{d^2 y}{dx^2} + A_1(x) \frac{dy}{dx} + A_2(x) y = G(x)$,

purposefully I am writing here capital G_x and with the condition, say y_a equal to 0 equal to y_b .

Now, after that we have discussed everything on $(())$ boundary value problem. So, the question is whatever theory, that we have discussed on $(())$ boundary value problem, that can be applied for this type of differential equation or not. So, we can put question in other way round, that whether this equation can be converted into the $(())$ boundary value problem format or not, such that operator will become a self adjoint operator? Answer is yes, this can be done because that $d^2 y / dx^2$, this equation can be multiplied by the function p_x and which results in $p_x d^2 y / dx^2$ plus $p_x A_1 x dy / dx$ plus $p_x A_2 xy$, that is equal to p_x into capital G_x .

This one now if we define p_x , this is equal to e to power integral $A_1 x dx$, then we can easily verify, that d/dx of p_x , this is going to be $A_1 x e$ to power integral $A_1 x dx$. So, that means, actually this is equal to p_x times $A_1 x$. So, if we define p_x in this particular way for the first two term of the last expression, that $p_x d^2 y / dx^2$ plus p_x times $A_1 x dy / dx$, these can be combined into to write d/dx of p_x into dy / dx . So, that means, these equation becomes d/dx of $p_x dy / dx$ plus $q_x y$, this is equal to g_x , where q_x is p_x times $A_2 x$ and small g_x , this is equal to p_x times capital G_x . And just note, that here we have made some rearrangement of the term of, you can use the transformation p_x equal to this one and in this process we have not disturbed anything on y .

So, that means, the boundary condition y_a equal to 0 equal to y_b , that remains unaltered. That means, this problem can be written as a $(())$ boundary value problem. Now, next is, that we are going to consider some particular problem, that how this type of boundary value problem can be solved in term of Green's function.

(Refer Slide Time: 14:58)

Ex.1 $\frac{d^2 y}{dx^2} - y = f(x), \quad y(0) = 0 = y(1)$

$\frac{d^2 y}{dx^2} - y = 0$

$\cosh x, \sinh x$

$\sinh x = 0$ for $x = 0$

$y_1(x) = C_1 \cosh x + C_2 \sinh x$

$y_1(x) = \sinh(1-x)$

$y_2(x) = \sinh x$

$y_1(1) = 0$
 $\Rightarrow C_1 \cosh 1 + C_2 \sinh 1 = 0$

So, first of all we consider this example, that is, $d^2 y / dx^2$ minus y , this is equal to $f(x)$ with the condition $y(0) = 0 = y(1)$. Of course, this is a simplified version of the $((\lambda))$ boundary value problems and at this moment we have no λ here, $p(x)$ is 1. So, of course, this is an equation of the form $((\lambda))$ boundary value problem.

Now, first of all we have to consider the corresponding homogenous equation, that is, $d^2 y / dx^2$ minus y , this is equal to 0. This is the homogenous ordinary differential equation associated with the given non-homogenous problem, two linearly independent solutions of this particular problem are actually cosine hyperbolic x and sine hyperbolic x .

Now, you can recall, in order to construct the Green's function for this problem we have to choose $y_1(x)$ and $y_2(x)$ in such a way, that $y_1(x)$ will satisfy the boundary condition on the right hand and $y_2(x)$ will satisfy the boundary condition on the left hand such that y_1 and y_2 , these two functions of x should be linearly independent. Now, clearly, for all real values of x cosine hyperbolic x is always positive. So, that means, this cosine hyperbolic x does not $((\lambda))$ either x is equal to 0 or at x equal to 1, but sine hyperbolic x , this is equal to 0 for x equal to 0. So, that means, the sine hyperbolic x , this is the solution of the homogenous problem and satisfying the boundary condition on the left. So, based upon this fact we can denote this sine hyperbolic x as $y_2(x)$.

Now, we have to find out a linearly independent function, which will be satisfying the left hand boundary conditions as none of them are satisfying the boundary condition and

equation is a linear equation. So, we can try to find out $y_1(x)$ into the format, that is linear combination of these two functions, that is, $c_1 \cosh(x)$ and $c_2 \sinh(x)$ and using the condition, that $c_1 \cosh(x) + c_2 \sinh(x)$ will be 0 at $x = 1$. You can find out c_1 and c_2 and ultimately will be having these results, that is, $y_1(x)$, this is equal to $\sinh(1-x)$. This can be easily obtained because if you claim $y_1(1) = 0$, that means, $y_1(1) = 0$.

So, this implies, $c_1 \cosh(1) + c_2 \sinh(1)$, this is equal to 0 and from here you can find out c_1 by $\sinh(1) = -c_2 \cosh(1)$ and taking this constant of proportion equal to 1, you can derive this quantity c_1 and c_2 . And after substituting you can find $y_1(x)$ equal to $\sinh(1-x)$. And of course, by the method of (C) you can verify these two solutions, that is, $\sinh(x)$ and $\sinh(1-x)$, they are actually two linearly independent solutions of the homogeneous equation.

(Refer Slide Time: 19:26)

The image shows a whiteboard with the following handwritten content:

$$G(x,s) = \begin{cases} \frac{1}{\alpha} \sinh(1-x) \sinh s, & 0 \leq s < x \leq 1 \\ \frac{1}{\alpha} \sinh x \sinh(1-s), & 0 \leq x < s \leq 1 \end{cases}$$

$$\left. \frac{\partial G(x,s)}{\partial x} \right|_{x=s+} - \left. \frac{\partial G(x,s)}{\partial x} \right|_{x=s-} = -\frac{1}{\alpha}, \quad b(x) = 1$$

$$\frac{\partial}{\partial x} \left[\frac{1}{\alpha} \sinh(1-x) \sinh s \right] \Big|_{x=s} - \frac{\partial}{\partial x} \left[\frac{1}{\alpha} \sinh x \sinh(1-s) \right] \Big|_{x=s} = -1$$

$$\Rightarrow -\frac{1}{\alpha} \cosh(1-s) \sinh s - \frac{1}{\alpha} \cosh s \sinh(1-s) = -1$$

$$\Rightarrow \frac{\sinh 1}{\alpha} = 1 \Rightarrow \alpha = \sinh 1$$

So, now, with this definition or this particular choice for $y_1(x)$ and $y_2(x)$ we can write the Green's function, $G(x,s)$, that is equal to $\frac{1}{\alpha} \sinh(1-x) \sinh s$ for $0 \leq s < x \leq 1$ and this is equal to $\frac{1}{\alpha} \sinh x \sinh(1-s)$ for $0 \leq x < s \leq 1$. So, this is the format.

Now, here if you applied the jump discontinuity of the derivative along the line s equal to x , then we can find $\frac{\partial}{\partial x} G(x, s)$ at x equal to s plus minus $\frac{\partial}{\partial x} G(x, s)$ at x equal to s minus, this is equal to minus 1 by 1 because here $\frac{\partial}{\partial x} G(x, s)$, this is equal to 1. So, $\frac{\partial}{\partial x} G(x, s)$, this will be equal to 1. So, this is nothing, but minus 1 by 1 and this x equal to s plus, that means, x greater than s .

So, therefore, from this definition of Green's function we can find this will be actually $\frac{\partial}{\partial x} G(x, s)$ of 1 by $\alpha \sinh(1-x) \sinh s$ minus $x \sinh(1-x) \sinh s$. Now, we can substitute x equal to s here because this is actually in order to choose the proper $G(x, s)$ and then minus integral, sorry, $\frac{\partial}{\partial x} G(x, s)$ of 1 by $\alpha \sinh(1-x) \sinh s$ times $\sinh(1-x) \sinh s$ at x equal to s . This is equal to minus 1 and this gives minus 1 by $\alpha \cosh(1-x) \sinh s$ minus 1 by $\alpha \cosh(1-x) \sinh s$ times $\sinh(1-x) \sinh s$. This is equal to minus 1 and this implies $\sinh(1-x) \sinh s$ divided by α equal to 1 in $(\)$ α equal to $\sinh(1-x) \sinh s$.

(Refer Slide Time: 22:37)

$$G(x, s) = \begin{cases} \frac{\sinh(1-x)\sinh s}{\sinh 1}, & 0 \leq s < x \leq 1 \\ \frac{\sinh x \sinh(1-s)}{\sinh 1}, & 0 \leq x < s \leq 1 \end{cases}$$

$$y(x) = - \int_0^1 G(x, s) f(s) ds$$

$$= - \int_0^x \frac{\sinh(1-x)\sinh s}{\sinh 1} f(s) ds - \int_x^1 \frac{\sinh x \sinh(1-s)}{\sinh 1} f(s) ds$$

So, therefore, finally, for the given problem $G(x, s)$, that is equal to $\sinh(1-x) \sinh s$ divided by $\sinh 1$ and $\sinh x \sinh(1-s)$ divided by $\sinh 1$. This is for $0 \leq s \leq x \leq 1$ and $0 \leq x \leq s \leq 1$ and $0 \leq x \leq 1$ and $0 \leq s \leq 1$ and therefore, solution to the given problem $y(x)$ is equal to minus integral 0 to 1 $G(x, s)$ than $f(s) ds$ and that is equal to, you can find, that minus integral 0 to x $\sinh(1-x) \sinh s$ divided by $\sinh 1$ times $f(s) ds$ minus integral x to 1 $\sinh x \sinh(1-s)$ divided by $\sinh 1$ times $f(s) ds$.

$x \sinh s$ divided by $\sinh 1$ minus $\int_x^1 \sinh(x-s) \sinh s$ divided by $\sinh 1$ ds. So, this is the solution to the given problem in terms of Green's function and if we know the particular form of $f(s)$, then we can find out the complete solution of the given problem.

And at this moment it comes to your mind, that this course is on integral equation, but I am here discussing a solution of the (---) boundary value problem, which is differential equation, but the point I like to make it clear here, that if we convert the given differential equation into the associated (---) integral equation of first or second time, that will come out after the derivation, and actually affix is non-zero. So, it will be non-homogenous (---) integral equation of the second time. Then, you can verify, for that problem this is going to be the solution of the integral equation.

(Refer Slide Time: 25:26)

The image shows a whiteboard with handwritten mathematical formulas. At the top, the Green's function $G(x, s)$ is defined as a piecewise function:
$$G(x, s) = \begin{cases} \frac{\sinh(1-x)\sinh s}{\sinh 1}, & 0 \leq s < x \leq 1 \\ \frac{\sinh x \sinh(1-s)}{\sinh 1}, & 0 \leq x < s \leq 1 \end{cases}$$
Below this, the integral equation for $y(s)$ is derived:
$$y(s) = - \int_0^1 G(x, s) f(x) dx$$

$$= - \int_0^x \frac{\sinh(1-x)\sinh s}{\sinh 1} f(x) dx - \int_x^1 \frac{\sinh x \sinh(1-s)}{\sinh 1} f(x) dx$$
At the bottom, an example problem is given:

Ex. 2 $\frac{d^2 y}{dx^2} + y = 1+x, \quad y(0) = 0 = y(\frac{\pi}{2})$

The corresponding homogeneous equation is:
$$\frac{d^2 y}{dx^2} + y = 0, \quad \sin x, \cos x$$

Now, we consider one more example where $f(x)$ is given such that you can verify the solution obtained by this method is actually satisfying the given equation. Here we consider the problem, that is, $\frac{d^2 y}{dx^2} + y = 1+x$ with the condition $y(0) = 0 = y(\frac{\pi}{2})$. So, now, this corresponding homogenous equation $\frac{d^2 y}{dx^2} + y = 0$, it has two linearly independent solution, one is $\sin x$, other is $\cos x$. And clearly, this $\cos x$ satisfies the boundary condition, at x is equal to $\frac{\pi}{2}$ $\sin x$ satisfies the boundary condition at x equal to 0. So, that means,

sine x satisfies the boundary condition on the left hand, cos x satisfies the boundary condition on the right hand.

(Refer Slide Time: 26:23)

$$y_1(x) = \cos x, \quad y_2(x) = \sin x$$

$$G(x, s) = \begin{cases} \frac{\sin s \cos x}{\alpha}, & s < x \\ \frac{\cos s \sin x}{\alpha}, & x < s \end{cases}$$

$$\frac{\partial}{\partial x} \left(\frac{\sin s \cos x}{\alpha} \right) \Big|_{x=s} - \frac{\partial}{\partial x} \left(\frac{\cos s \sin x}{\alpha} \right) \Big|_{x=s} = -1$$

$$\Rightarrow -\frac{\sin^2 s}{\alpha} - \frac{\cos^2 s}{\alpha} = -1 \Rightarrow \alpha = 1$$

$$G(x, s) = \begin{cases} \sin s \cos x, & 0 \leq s < x \leq 1 \\ \cos s \sin x, & 0 \leq x < s \leq 1 \end{cases}$$

So, therefore, we can denote them as cos x as $y_1(x)$ and sine x as $y_2(x)$ and therefore, this Green's function $G(x, s)$, this will be sine s cosine x divided by alpha. This is for s less than x and cosine s sine x divided by alpha. This is for x less than s and again, using the jump discontinuity of the Green's function, that is the derivative of the Green's function we can find $\frac{\partial}{\partial x} G(x, s)$ for x greater than s.

So, that means, here we have to apply on sine s cosine x, then substituting x equal to s minus $\frac{\partial}{\partial x}$ of minus $\frac{\partial}{\partial x}$ of cosine s sine x divided by alpha with x equal to s, that is equal to minus 1 because p is equal to 1 here. So, this gives minus sine square s divided by alpha minus cosine square s divided by alpha. This is equal to minus 1 implying alpha equal to 1 and therefore, this Green's function $G(x, s)$, this is equal to simply sine s cosine x and cosine s sine x. This is valued for 0 less than equal to s less than x less than equal to 1 and this is 0 less than equal to x less than s less than equal to 1. So, these are the definitions.

(Refer Slide Time: 28:42)

$$\begin{aligned}
 y(x) &= - \int_0^{\frac{\pi}{2}} G(x,s)(1+s) ds \\
 &= - \int_0^x G(x,s)(1+s) ds - \int_x^{\frac{\pi}{2}} G(x,s)(1+s) ds \\
 &= - \int_0^x \sin s \cos x (1+s) ds - \int_x^{\frac{\pi}{2}} \cos s \sin x (1+s) ds \\
 &= - \cos x \left[-(1+s) \cos s + \sin s \right]_0^x - \sin x \left[(1+s) \sin s + \cos s \right]_x^{\frac{\pi}{2}} \\
 &= - \cos x \left[-(1+x) \cos x + \sin x + 1 \right] - \sin x \left[1 + \frac{\pi}{2} - (1+x) \sin x - \cos x \right] \\
 &= 1 + x - \sin x - \cos x - \frac{\pi}{2} \sin x
 \end{aligned}$$

And therefore, the solution to the given problem, that is, $y(x)$ is equal to minus integral 0 to π by 2 $G(x, s)$, this will be 1 plus s ds . So, first of all we divided into two intervals, that is, 0 to x $G(x, s)$ 1 plus s ds minus x 2 π by 2 G of (x, s) times 1 plus s ds and here this will be minus integral 0 to x . First integral s is less than x , so (s) is less than x . So, this is sine s cosine x . So, therefore, this will be sine s cosine x 1 plus s ds minus integral x 2 π by 2 cosine s sine x 1 plus s ds . And using the formula for integration by parts, cosine x can be taken out of the integral and then we have to use (s) formula considering 1 plus s as the first function u and sine s as the second function v .

So, we will be having this minus 1 plus s cosine s because integral of sine s minus cosine s , then (s) will involve minus sine combined with this 1 plus 1 derivative of 1 plus s is 1, so plus cosine s . And after integration this will be plus sine s limit 0 to x and for the second integral minus sine x can be out of the integral sign, then it will be 1 plus s sine s plus cosine s limit x 2 π by 2 and this is equal to minus cosine x at the upper limit minus 1 plus x cosine x plus sine x . At the lower limit cosine 0 is 0, so this will be plus 1 and no contribution from the sine x term. Then, minus sine x , this will be 1 plus π by 2 into 1 sine x is 1. There is no contribution from cosine at y by 2 is 0 and then minus 1 plus x sine x minus cosine x .

Now, you just check, that these two terms can be combined together, this one and this one, they actually produce the term 1 plus x and then these two terms cancels with each

other, that is, this one and this one. So, then we are left with minus sine x minus cosine x and minus pi by 2 sine x. So, this is actually solution of the non-homogenous boundary value problem, that is, $d^2 y / dx^2 + y = 1 + x$ subjected to the boundary condition, that is, $y(0) = 0$ as well as $y(\pi/2) = 0$, that is also equal to 0.

Next, we are going to consider some properties of Eigen values and Eigen functions associated with the **(C)** boundary value problem from where we can define, that set of orthogonal function and the infinite collection of set of orthogonal functions will gives us opportunity to expand any given function, which of course, satisfies certain differentiability and continuity condition such that infinite series will converge uniformly, then those functions can be expressed as an infinite series of this orthogonal functions, that means, those functions can be generated with the help of the collection of familiar orthogonal functions.

(Refer Slide Time: 33:41)

$$\frac{d}{dx} \left[p(x) \frac{dy}{dx} \right] + (q(x) + \lambda r(x)) y = 0$$

$$m_1 y(a) + m_2 y'(a) = 0, \quad m_3 y(b) + m_4 y'(b) = 0$$

$$x \in [a, b]$$

Let $y(x)$ and $z(x)$ are solⁿs of the SL-BVP corr to λ and μ respectively with $\lambda \neq \mu$. Further

$$\left[p(x) W(y(x), z(x)) \right]_a^b = 0, \text{ then,}$$

$$\int_a^b r(x) y(x) z(x) dx = 0$$

$$W(y(x), z(x)) = \begin{vmatrix} y(x) & z(x) \\ y'(x) & z'(x) \end{vmatrix}$$

Now, first of all we consider some particular property of these problems. So, throughout the rest of the part of the discussion we will be considering this equation, that is, $d/dx [p(x) dy/dx] + q(x) y = \lambda r(x) y$ equal to 0 with the boundary conditions, that is, separated boundary conditions $m_1 y(a) + m_2 y'(a) = 0$ and $m_3 y(b) + m_4 y'(b) = 0$ where this $p(x)$, $q(x)$ and $r(x)$ they are continuous. And we are assuming, that $p(x)$ is non-zero for all values x within the range, that is, x belongs this close interval a, b .

Now, first of all we are going to prove a result, that let y_x and z_x are solutions of the $(())$ boundary value problem corresponding to λ and μ respectively with $\lambda \neq \mu$. Further, further this condition, that is, p_x and wronskian of $y_x z_x$, this is from a to b is equal to 0, then $\int_a^b r(x) y_x z_x dx$. This is equal to 0.

And here, just for your quick reference, wronskian of y_x and z_x is nothing, but determinant $y_x z_x y'_x z'_x$. So, that means, for λ y_x is solution for μ , z_x is the solution in these conditions, that is, p_x multiple by wronskian of $y_x z_x$ from a to b . This is equal to 0, then this condition is satisfied $\int_a^b r(x) y_x z_x dx = 0$. And whenever this condition is satisfied, that means, $\int_a^b r(x) y_x z_x dx = 0$. Then, we say, that y and z , they are orthogonal functions to each other with respect to the weight function $r(x)$ depending upon the associated $(())$ boundary value problem. If $r(x) = 1$, then condition for orthogonality will come down to simply $\int_a^b y_x z_x dx$, this is equal to 0.

(Refer Slide Time: 37:30)

$$\begin{aligned} \frac{d}{dx} \left[p(x) \frac{dy}{dx} \right] + (q(x) + \lambda r(x)) y(x) &= 0 \quad \text{--- (i)} \\ \frac{d}{dx} \left[p(x) \frac{dz}{dx} \right] + (q(x) + \mu r(x)) z(x) &= 0 \quad \text{--- (ii)} \\ \text{(ii)} \times z(x) - \text{(i)} \times y(x) &\Rightarrow \\ y(x) \frac{d}{dx} \left[p(x) \frac{dz}{dx} \right] + (q(x) + \mu r(x)) y(x) z(x) & \\ - z(x) \frac{d}{dx} \left[p(x) \frac{dy}{dx} \right] - (q(x) + \lambda r(x)) y(x) z(x) &= 0 \\ \Rightarrow y(x) \frac{d}{dx} \left[p(x) \frac{dz}{dx} \right] - z(x) \frac{d}{dx} \left[p(x) \frac{dy}{dx} \right] + (\mu - \lambda) r(x) y(x) z(x) & \\ \Rightarrow \frac{d}{dx} \left[p(x) (y(x) z'(x) - z(x) y'(x)) \right] = (\lambda - \mu) r(x) y(x) z(x) & \end{aligned}$$

So, first of all we prove this result, y_x is the solution of $(())$ problem for λ . So, that means, $\frac{d}{dx} [p(x) \frac{dy}{dx}] + q(x) + \lambda r(x)$, this times y_x , this is equal to 0, call it one. And $\frac{d}{dx} [p(x) \frac{dz}{dx}] + q(x) + \mu r(x)$ multiplied by y_x , this is equal to 0, call it two. Now, if we multiply second equation by z_x and first by y_x and then subtract, this implies we will be having that, sorry, multiplying 2 by y_x and 1 by z_x , then we can find, that y_x multiplied with $\frac{d}{dx} [p(x) \frac{dz}{dx}] + q(x) + \mu r(x)$ this into $y_x z_x$ minus z_x

multiplied with d of $p(x) y(x) z(x)$ minus $q(x) y(x) z(x)$ plus $\lambda r(x) y(x) z(x)$, this will be equal to 0. Here, in equation two this will be actually $z(x)$.

Now, you can see, that $q(x) y(x) z(x)$ and $q(x) y(x) z(x)$ cancels from, cancels with each other. So, then rest of the expression we can combine as $y(x)$ with d of $p(x) dz(x)$, then minus $z(x)$ times d of $p(x) dy(x)$, this expression plus μ minus $\lambda r(x) y(x) z(x)$. And now, you can recall from the previous discussion, that this part, that is, $y(x) d$ of $p(x) dz(x)$ minus $z(x) d$ of $p(x) dy(x)$, this is nothing, but the derivative of $p(x)$ multiplied with $y(x) z(x)$ dashed x minus $z(x) y(x)$ dashed x , this is equal to λ minus μ $r(x) y(x) z(x)$. And this expression $y(x) z(x)$ dot minus $z(x) y(x)$ dot is nothing, but the wronskian of y and z .

(Refer Slide Time: 41:35)

The image shows a whiteboard with the following handwritten content:

$$d [p(x)W(y(x), z(x))] = (\lambda - \mu) r(x) y(x) z(x) dx$$

$$\left[p(x)W(y(x), z(x)) \right]_a^b = (\lambda - \mu) \int_a^b r(x) y(x) z(x) dx$$

$$\lambda \neq \mu$$

$$\Rightarrow \int_a^b r(x) y(x) z(x) dx = 0$$

Let $y_m(x)$ and $y_n(x)$ be two eigenfunctions of the SL-BVP $(py')' + (q + \lambda r)y = 0, x \in [a, b]$

$$m_1 y(a) + m_2 y'(a) = 0 = m_3 y(b) + m_4 y'(b)$$

And therefore, we can write, that d of $p(x) W(y(x), z(x))$, this is equal to λ minus μ $r(x) y(x) z(x) dx$. And then, integrating from a to b we can find $p(x) W(y(x), z(x))$, this limit a to b , that is equal to λ minus μ integral a to b $r(x) y(x) z(x) dx$. And since this is given to be 0 and with the condition λ not equal to μ , this implies, that integral a to b $r(x) y(x) z(x) dx$, this is actually equal to 0.

So, that means, for two **(())** boundary value problem, one with parameter λ and other with parameter μ with same P, q, r , if you are able to find out two corresponding solution of the equations, which are denoted by $y(x)$ and $z(x)$ such that $p(x)$ wronskian $y(x) z(x)$ evaluated at b minus the same expression evaluated at a , is equal to 0. Then, these two functions y and z are orthogonal to each other with respect to the weight function r .

Next, we are going to prove, that for a particular (()) boundary value problem we are able to find out two non-trivial solutions, that means, Eigen values and Eigen functions and if two Eigen functions are corresponding to two distinct Eigen values, then those Eigen functions are actually orthogonal functions. So, in order to prove this, first of all we are going to prove this result, that let $y_m(x)$ and $y_n(x)$ be two Eigen functions, be two Eigen functions of the (()) boundary value problem. In short, we can write $p y' + q y + \lambda r y = 0$, where x belongs to (a, b) with the boundary conditions $m_1 y(a) + m_2 y'(a) = 0$ and $m_3 y(b) + m_4 y'(b) = 0$.

(Refer Slide Time: 45:00)

corr. to two distinct eigenvalues λ_m and λ_n respectively,
then $\left[p(x)W(y_m(x), y_n(x)) \right]_a^b = 0$.

$$\left[p(x)W(y_m(x), y_n(x)) \right]_a^b = p(b)(y_m(b)y'_n(b) - y'_m(b)y_n(b)) - p(a)(y_m(a)y'_n(a) - y'_m(a)y_n(a)) = 0$$

$m_1 y_m(a) + m_2 y'_m(a) = 0$ Assume, $m_1 \neq 0$
 $m_1 y_n(a) + m_2 y'_n(a) = 0$

$$m_2 = -\frac{m_1 y_m(a)}{y'_m(a)} \Rightarrow m_1 [y_m(a)y'_n(a) - y'_m(a)y_n(a)] = 0$$

$$y_m(a)y'_n(a) - y'_m(a)y_n(a) = 0$$

Corresponding to two distinct Eigen values, two distinct Eigen values λ_m and λ_n respectively, then $p(x)$ wronskian of $y_m(x)$ and $y_n(x)$ from a to b , this is equal to 0. This is one of the important results that we can prove. So, if we look at this expression, that is, $p(x)$ wronskian $y_m(x)$ and $y_n(x)$ from a to b , this is equal to $p(b)(y_m(b)y'_n(b) - y'_m(b)y_n(b)) - p(a)(y_m(a)y'_n(a) - y'_m(a)y_n(a)) = 0$. We have to prove this.

Now, recall, that whenever we have mentioned, that the boundary condition, then we have mentioned m_1 and m_2 are not simultaneously equal to 0. Now, y_m and y_n , they are solution of (()) boundary value problem because they are Eigen functions. So, that means, y_m satisfies the left hand boundary condition, that is, $m_1 y_m(a) + m_2 y'_m(a) = 0$ and $m_1 y_n(a) + m_2 y'_n(a) = 0$.

Now, without any loss of generality we can assume, that $m_1 \neq 0$, this is not equal to 0 because initially we have mentioned, that m_1 and m_2 are simultaneously equal to 0. So, therefore, we are assuming $m_1 \neq 0$. If $m_1 \neq 0$, then from the first relation we can write, we can write m_2 , this is equal to minus $m_1 y_m$ divided by y_m dashed a . So, that means, then we can substitute m_2 in this expression. That means, eliminating m_2 between these two relations we can find m_1 times y_m y_n dot a minus y_n y_m dot a , this is equal to 0. Now, already we have assumed $m_1 \neq 0$. So, therefore, we must have y_m y_n dot a minus y_n y_m dot a , this is equal to 0. Now, of course, with assumption $m_2 \neq 0$ you can arrive at the same result, as well as, if m_1 and m_2 both of them are not equal to 0, then in that case also you can arrive at the same result. Here, for simplicity I have proceeded with this assumption, that is, $m_1 \neq 0$, so this is equal to 0.

(Refer Slide Time: 49:43)

The image shows a digital whiteboard with the following handwritten content:

$$y_m(b) y_n'(b) - y_n(b) y_m'(b) = 0$$

$$\left[p(x) w(y_m(x), y_n(x)) \right]_a^b = 0$$

$(\lambda_m, y_m(x)), (\lambda_n, y_n(x))$ $Ly = 0, \dots$

$$\lambda_m \neq \lambda_n$$

$$\int_a^b r(x) y_m(x) y_n(x) dx = 0$$

Similarly, from the second condition, now you can easily guess, that from the second condition we will be able to derive, that y_m b times y_n dot b minus y_n b times y_m dot b this is equal to 0. So, combining these two results, that is, y_m y_n dot a minus y_n y_m dot a equal to 0. And then, y_m b y_n dot b minus y_n b y_m dot b , this is equal to 0. You can derive, that $p(x)$ wronskian of $y_m(x)$ $y_n(x)$ from a to b , this is equal to 0.

So, that means, from this result we can conclude, that for $(())$ boundary value problem, if $y_m(x)$ and $y_n(x)$ are two Eigen functions corresponding to distinct Eigen values, λ_m

m and λ_n , then they are orthogonal to each other because in the last result we have established, if y_1 and y_2 are two solutions such that $p(x)w'(y) - y'w(x)$ from a to b , this is equal to 0. Then, $\int_a^b r(x) y_1(x) y_2(x) dx$, that is equal to 0.

So, combining these two results we can say, that $(\lambda_m, y_m(x))$ is an Eigen pair; $(\lambda_n, y_n(x))$, this is another Eigen pair associated with the homogenous $(L y = 0)$ boundary value problem with the separated boundary conditions, and $\lambda_m \neq \lambda_n$. Then, $\int_a^b r(x) y_m(x) y_n(x) dx$, this is equal to 0. So, this is the result.

So, that means, two distinct Eigen functions corresponding to different Eigen values λ_m and λ_n , they are orthogonal to each other. So, that means, today we have established this result. In the next lecture we will be proving, that under certain conditions satisfied by $r(x)$, that means, if $r(x)$ maintains the same sign toward the interval a to b , then all the Eigen values are real and then we will define the important class of functions associated with the orthogonal function, that is familiar of ortho-normal functions. And from there we can find either Fourier series expansion when this orthogonal functions are trigonometric functions or in general, expansion of a function in terms of infinite dimensional orthogonal functions such that every function can be expressed as a linear combination of those functions. And we will be discussing how the coefficients of those series, in terms of the orthogonal functions, can be derived using all these properties of the Eigen functions associated with a $(L y = 0)$ boundary value problem.

Thank you for your attention.
