

Calculus of Variations and Integral Equation

Prof. Dharendra Bahuguna

Department of Mathematics and Statistics

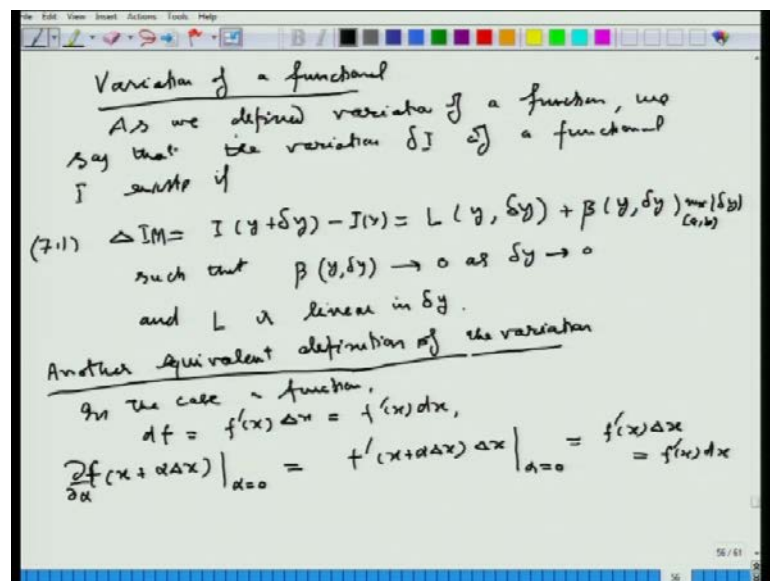

Indian Institute of Technology, Kanpur

Module No. # 01

Lecture No. # 08

Welcome viewers to the NPTEL lecture series on the Calculus of Variations; this is the 8th lecture of the series. In the last lecture, we had got introduced to the concept of variation of a functional.

(Refer Slide Time: 00:33)

We first recalled the definition of the differential of a function, which was defined like this, we had a function $f(x)$ from a to b to \mathbb{R} and we considered its differential are defined as $df = f'(x) dx$ where for independent variable x $dx = \Delta x$. So, for independent variable the differential is equal to the increment itself.

(Refer Slide Time: 00:39)

Continuity: $f: [a, b] \rightarrow \mathbb{R}$ is called continuous at $x \in (a, b)$ if $\forall \epsilon > 0 \exists \delta = \delta(\epsilon, x) > 0$ such that for $|z - x| < \delta \Rightarrow |f(z) - f(x)| < \epsilon$.

$\Delta I = I(y + \delta y) - I(y)$
 I is called continuous at y if $\forall \epsilon > 0 \exists \delta = \delta(\epsilon, y) > 0$ s.t. $|I(y + \delta y) - I(y)| < \epsilon$.

(Refer Slide Time: 00:41)

A function $f: [a, b] \rightarrow \mathbb{R}$ is called linear if $\left. \begin{aligned} f(x+y) &= f(x) + f(y) \\ f(cx) &= c f(x) \end{aligned} \right\} \begin{aligned} x, y &\in [a, b] \\ c &\in \mathbb{R} \end{aligned}$

if $I: A[a, b] \rightarrow \mathbb{R}$ is called linear if $\left. \begin{aligned} I(y_1 + y_2) &= I(y_1) + I(y_2) \\ I(cy) &= c I(y) \end{aligned} \right\} \begin{aligned} y_1, y_2 &\in A[a, b] \\ c &\in \mathbb{R} \end{aligned}$

Example
 $I(y) = \int_{x_1}^{x_2} [p(x)y + q(x)y'] dx$
 I is linear.

So, for a function f we saw that its increment Δf is actually equal to $f(x + \Delta x)$ minus $f(x)$, and that if f is differentiable then, it can be written as $\Delta f \approx f'(x) \Delta x$ as we have seen, in the case of a function we have.

(Refer Slide Time: 01:28)

$$I(y) = \int_{x_1}^{x_2} F(x, y(x), y'(x)) dx$$

$$\Phi(\alpha) = I(y + \alpha \delta y) = \int_{x_1}^{x_2} F(x, y(x) + \alpha \delta y(x) + y'(x) + \alpha \delta y'(x)) dx$$

$$\delta y(x) = \eta(x) - \gamma(x)$$

$$y(x) + \alpha \delta y(x) = y(x) + \alpha (\eta(x) - \gamma(x))$$

$$y'(x) + \alpha \delta y'(x) = y'(x) + \alpha (\eta'(x) - \gamma'(x))$$

$$\frac{\partial I}{\partial \alpha} (y + \alpha \delta y) = \int_{x_1}^{x_2} [F_{y(x) + \alpha \delta y(x)} \delta y(x) + F_{y'(x) + \alpha \delta y'(x)} \delta y'(x)] dx$$

$$\text{since } \delta y'(x) = (\delta y(x))'$$

$$\text{Hence } \frac{\partial I}{\partial \alpha} (y + \alpha \delta y) = \int_{x_1}^{x_2} [F_{y(x) + \alpha \delta y(x)} - \frac{d}{dx} F_{y'(x) + \alpha \delta y'(x)}] \delta y(x) dx$$

(Refer Slide Time: 01:34)

$$F_y - \frac{d}{dx} F_{y'} = 0$$

$$\text{Euler's Equation.}$$

$$\Delta f(x) = f(x + \Delta x) - f(x) = f'(x) \Delta x + \beta(x, \Delta x) \Delta x$$

$$\Delta I(y) = I(y + \delta y) - I(y) = L(y, \delta y) + \beta(y, \delta y) \|\delta y\|_0$$

$$L(y, \delta y) = \int_{x_1}^{x_2} [F_{y(x)} \delta y(x) + F_{y'(x)} \delta y'(x)] dx$$

$$\beta(y, \delta y) \rightarrow 0 \text{ as } \|\delta y\|_0 \rightarrow 0$$

$$\text{and } \delta y = L(y, \delta y) - \text{linear part in the increment.}$$

Here, delta f equal to f of x plus delta x minus f of x, and if f is differentiable, then we saw that this is actually equal to f prime x delta x or d x is same thing d x plus some beta x delta x times delta x. Similarly, for the functional I y, we saw at this the increment delta I y, which is a same thing as the difference I at y plus this delta small delta y denotes the variation in y which is, so delta y we know that delta y equal to y tilde x minus y x, this is the difference between the ordinates of 2 curves y x and y tilde x.

So, for this minus I of y and we say that, like we defined f is differentiable if and only if, the following holds then similarly, for the functional I we say that, I the variation ΔI exists small ΔI , small ΔI exists if and only if, if this increment capital ΔI which is by definition I of y plus Δy minus I Y , if this difference is equal to here some linear part in the increment, which is function of y as well as this variation Δy and plus some $\beta y \Delta y$ and here, the absolute value of this maximum of $\text{mod } \Delta y$, here this maximum is that, maximum norm in c_k .

See for any c_k , x_1 to x_2 if y belongs to this, we define this norm here, for k equal to 0 we define norm of y which is maximum of $\text{mod } y$ maximum over x_1, x_2 interval and if k equal to 1, we define this as norm this as 0 norm we can say and then y_1 norm, maximum over x_1 to x_2 of $\text{mod } y$ plus $\text{mod } y'$ x , maximum separately we take maximum of this plus maximum of x_1 to x_2 of y' x (Refer Slide Time: 04:45).

So, similarly for any general k we take y_k , for general k we take the c_k norm as summation maximum over x_1 to x_2 of this y_j norm j equal to maximum of Y_j j th derivative of x like this. So, here we take the zeroth norm that is this one maximum here. So, we say that this increment ΔI if this difference is of the form if it can be expressed as $l y \Delta y$ plus $\beta, \Delta y$ comma Δy and this is the zeroth norm define this of the increment Δy this can also be written like this $l y \Delta y$ plus $\beta y \Delta y$ and this is zeroth here maximum of this is like this and zeroth norm like this **this** (Refer Slide Time: 05:47).

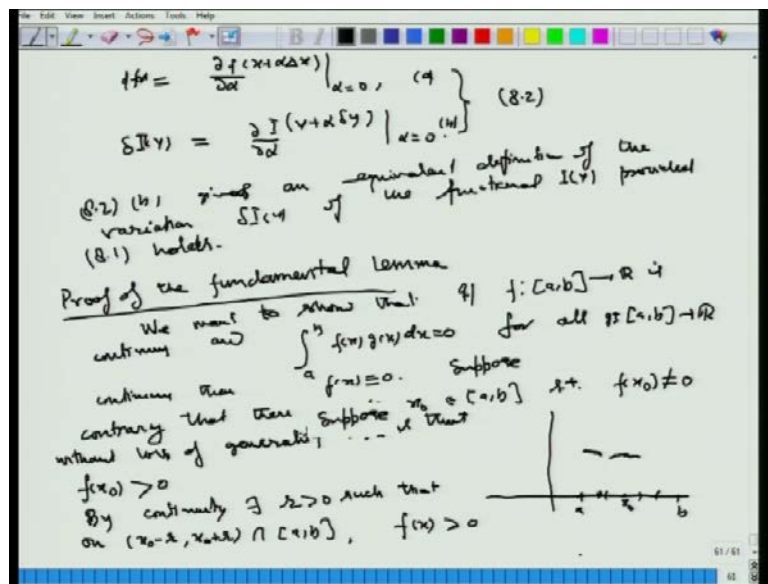

This maximum is over that interval x_1 to x_2 , so here and this l in this linear in, so $L y \Delta y$ is linear, let us say this is 8.1 in 8.1, we have $L y \Delta y$ is linear in Δy and this $\beta y \Delta y$ **delta y... sorry this** is small Δy , because like in independent variable here $d x$ and Δx are same similarly, here for this independent variable y , here we will have this increment and the variation same (Refer Slide Time: 6:47).

So, this Δy this goes to 0 as this maximum Δy 0 norm goes to 0 (Refer Slide Time: 8:00). So, we say that this I the functional I , has variation this ΔI y provided 8.1 holds and this linear part and this Δy is defined as $l y \Delta y$ which is the linear part in the increment.

So, that is the definition, here this linear part like **here this linear part** is called differential, we say that this $d f$ equal to $f' x d x$, so that is what is called

differential. Same way we define the variation δy here which is the linear part in this increment given by 8.1, if 8.1 holds for the functional I , so this was **equivalently then defined**, so by the fact that this df is also df of x plus $\alpha \delta x$ over $\delta \alpha$ at α equal to 0, **same way this we have seen α equal to zero** same way this we have seen that the, this $\delta I y$, here is this is df at x of this, and then this is defined as $\delta I y$ plus $\alpha \delta y$ over $\delta \alpha$ **α equal to 0**.

(Refer Slide Time: 09:48)

Here, this is an equivalent definition of this, this is 8.2, so here this second part of this 8.2 let say this a and this is b . So, 8.2 b gives an equivalent definition of the variation $\delta I y$ of the functional $I y$ provided 8.1 holds.

We are saying that variation exist if and only if 8.2 hold, so under that assumption we see that the equivalent definition of the variation δI , can be given by this 8.2 b and so this is what we use for getting necessary condition, which is Euler's equation for any function **any function** optimizing the functional I .

So, that is what we have got in the last lecture, here we have got. So, for this functional we saw that, so this functional we considered that is the first step here the simplest one where we $I y$ is given by $\int_{x_1}^{x_2} f(x, y, y', x) dx$; here, y is assume to satisfy certain additional conditions than continuity, because this integral involves y' and so this **should be** integral should be defined in the sense of Riemann.

So, y is assumed to **to** be in the admissible class where y' will have a smoothness property. So, here this function, functional I is unchanged to function $\phi(\alpha)$ **using this** using this substitution here, $I(y + \alpha \delta y)$. So, then it becomes $\int_{x_1}^{x_2} f(x, y + \alpha \delta y, y' + \alpha \delta y')$, because here δy is taken like this $y' + \alpha \delta y'$, and here only α is changing this y and y' are fixed here, only we are changing α therefore, this functional it then becomes only function of α , and we use the usual rule of finding the values of α for which this ϕ will become maximum. So, we see that **if y has to** if y has to optimize, because y is obtained when α is taken 0, so we see that in the necessary condition for y to optimize this is the $\phi'(\alpha)$ must be 0 at $\alpha = 0$.

So, that is what we impose, here we differentiate this functional with respect to α partially and we get the following $\int_{x_1}^{x_2} f_y \delta y + \delta y' \int_{x_1}^{x_2} f_{y'} \delta y'$ and then this argument is differentiated with respect to α , which leaves δy plus, then f is differentiated with this third argument that is $y' + \alpha \delta y'$, and then this is differentiated with respect to α which leaves $\delta y'$.

Now, here with this second term in the integrand we use integration by parts, here we shift this derivative onto this $f_{y'} \delta y'$ which gives us this minus $\frac{d}{dx} f_{y'} \delta y + f_{y'} \delta y'$. And here, this term is not disturbed and so we take out this which is feed from here δy ; and we take that common from both the terms here, and we get the boundary terms like this evaluated at x_1 to x_2 .

Now, since at the moment we are taking only fixed boundary conditions that the points a and b are fixed and therefore, since y and \tilde{y} pass through these 2 points, so we get δy at x_1 and δy at x_2 equal to 0; because **delta y** since δy at x is $\tilde{y} - y$ and therefore, this at x_1 as well as x_2 will be 0, because both y and \tilde{y} are passing through the points a and b , and so we get this $\frac{\delta I}{\delta \alpha}$ partial derivative of this $I(y + \alpha \delta y)$ the following, because the boundary term vanishes (Refer Slide Time: 15:34).

And here we use the fundamental, so we put $\alpha = 0$ here, which then gives us this 7.2 which was described in the last lecture and now, this integrand has to be 0, which follows from since this variation is arbitrary here, because all this y and \tilde{y} or you can take any arbitrary y and \tilde{y} and therefore, this is true for any variation here and

therefore, we use the fundamental lemma of the calculus of variation like this; that if you have two functions f and g continuous, if we have this function f fixed function which is continuous from a to b to \mathbb{R} and this integral $\int_a^b f(x)g(x)dx = 0$ for all continuous functions on this interval then $f(x)$ must be identically 0.

So, this is to be proved which will establish today in this lecture, so we use this to conclude that this integrand is 0 and that is what is called Euler's Equation, so Euler's Equation is the necessary condition for y to optimize the functional I , so here we establish this fundamental lemma, so this proof of the fundamental lemma. So, we want to show that, to show that if f from a to b to \mathbb{R} is continuous and $\int_a^b f(x)g(x)dx = 0$ for all g from a to b on \mathbb{R} continuous, then $f(x)$ must be identically 0, so suppose contrary that $f(x)$ is not identically 0, **so suppose contrary that there exists x_0** their exists x_0 in the interval a to b such that, $f(x_0)$ is 0 is not equal to 0; now here if situation can occur that it could be either a or b . So, is like this if x_0 is a or b , so if $x_0 = a$ then $f(x_0)$ could be here or it could be below here, so we can multiply by minus, we can replace f by minus f , and assume that it is on the upper side of this x_0 .

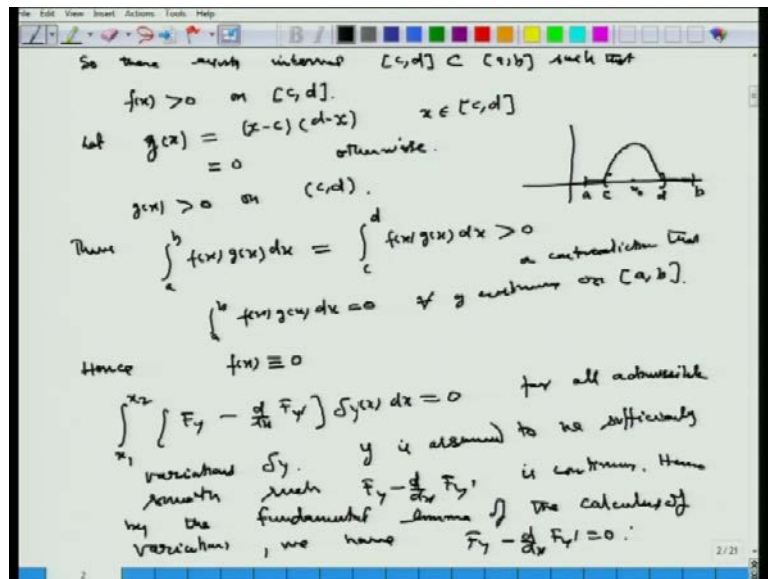

So, without loss of generality, suppose that $f(x_0)$ is positive since it is not 0, so either it is negative or it is positive. So, assuming that if it is negative we can multiply by minus and then consider minus $f(x)$ instead of $f(x)$, and then conclude for minus $f(x)$ and whatever holds for minus $f(x)$ with than conclude from that for $f(x)$. So, we can assume without loss of generality that $f(x_0)$ is positive here, so if it is at the end points then we take only, if it is the left end point we take the interval; some interval never would round a on the right of this and if it is the right end point, then we take neighborhood around this point around b in the inside interval a, b ; if it is an interior point like this than we can take neighborhood around this x_0 , so there exists, so by continuity there exists r greater than 0 **such that** such that here, $(x_0 - r, x_0 + r) \cap (a, b)$ such that on $f(x)$ is positive.

Like since it is positive, so by continuity it, continuous to remain above here, so there is the neighborhood around this such that, this is will remain here. Similarly, if it is here then some were $f(x_0)$ is 0 here and so by continuity remains above the x axis similarly, if it is the right end point then it remains above like this by continuity, so we will have this thing.

Now, we construct here, so by continuity there exists r greater than 0 such that on this interval neighborhood around x_0 , so $x_0 - r$ to $x_0 + r$ intersection a, b , so if this is x_0 is interior point then this can be taken in **in** inside. So, and this intersection will be this interval $x_0 - r$ to $x_0 + r$ itself, but if it if x_0 is the end point, then only the right side of that will come in the intersection or if x_0 is the right end point that is b then you will have only the left side of this interval coming in the intersection.

So, that way we have a neighborhood around here this either this end point or if x_0 is interior point then like this and if x_0 is the right end point b then we have this interval around this which we can denote.

(Refer Slide Time: 23:51)

So, there exist interval let us say c, d which is inside a, b such that, this $f(x)$ is positive on c, d ; now we construct η like this, so we construct η let $\eta(x) = (x - c)(d - x)$. Here, if x belongs to c, d and $g(x) = \eta(x)$ otherwise, then we can see that here on this interval, **if it is so this is right** if x_0 is right end point then c, d can be taken like this, if it is interior point the c, d interval can be taken like this or c, d interval can be taken right like this if x_0 is right end point.

So, this interval here η will be taken positive like this and vanishing at the end points as well as at the other parts, so η is like this or the $g(x)$ rather, so here you have this interval a to b (Refer Slide Time: 25:28). So, let us see supposing that x_0 is here interior

and you have this interval c, d like this, so $g(x)$ is something like parabola like this, this is parabola here.

And here it is 0 end point that c also it is 0 and here this is 0 and on c and d it is strictly positive, and so $g(x)$ is positive on open interval (c, d) , thus $\int_a^b f(x)g(x)dx$ is since, the $g(x) > 0$ outside, so it reduces to $\int_c^d f(x)g(x)dx$ and here both the things are strictly positive, so we get strictly positive a contradiction **diction** that $\int_a^b f(x)g(x)dx = 0$ for all g , all continuous g , continuous on a to b , really g is continuous here, but the $\int_a^b f(x)g(x)dx$ is strictly positive it is not 0. So, there cannot be such a case that, so therefore, hence $f(x)$ must be identically 0, so now, we have got this, now here we have seen that x_1 to x_2 $f(y)$ minus d by dx of $f(y)$ prime δy dx equal to 0, and this is for all admissible variations δy , here we are assuring that, y is assumed to be sufficiently smooth such that, $f(y)$ minus d by dx of $f(y)$ prime is continuous. Hence by the fundamental **fundamental** theorem lemma of the calculus of variations; we have this $f(y)$ minus d by dx of $f(y)$ prime equal to 0, which is Euler's equation, is known as Euler's equation.

(Refer Slide Time: 30:04)

The image shows a handwritten derivation of Euler's equation for a specific functional. The steps are as follows:

- Example 1:**
$$J(y) = \int_0^1 [y'^2 - y^2] dx$$

$$y(0) = 0 \quad y(1) = 1.$$
- Comparing J with
$$J(y) = \int_a^b F(x, y(x), y'(x)) dx,$$
- we have
$$F(x, y, y') = y'^2 - y^2.$$
- So Euler's Equation
$$F_y - \frac{d}{dx} F_{y'} = 0 \Rightarrow$$
- $$-2y - \frac{d}{dx}(2y') = 0$$
- $$\Rightarrow y + y'' = 0 \quad \text{which has the general solution}$$
- $$y(x) = A \cos x + B \sin x$$
- $$y(0) = 0 \Rightarrow A = 0 \quad \text{hence } y(x) = B \sin x.$$
- Now $x=1 \Rightarrow B \sin 1 = 1 \quad B = \frac{1}{\sin 1}.$
- Hence
$$y(x) = \frac{\sin x}{\sin 1}.$$

So, let us see some applications of Euler Equation, here we consider a few examples, the first 1 is, we consider few examples, the first 1 is let us consider, $I y$ integral 0 to 1 y prime square minus y square dx $y(0) = 0$ and $y(1) = 1$.

So, here we have the integrand F , so comparing it with the general form, so comparing it with the general form $I(y) = \int_0^1 F(x, y, y') dx$, we have $F(x, y, y')$ equal to $y'^2 - y^2$. So, Euler Equation $F_y - \frac{d}{dx} F_{y'} = 0$ implies in this case that $-2y = -2y'$ here, $-2y = -2y'$ implies $y = y'$ and which has solution, general solution rather as $y = A \cos x + B \sin x$. Now, we use the boundary conditions $y(0) = 0$ implies $A = 0$, so then hence $y = B \sin x$, now $y(1) = 1$ implies that $B \sin 1 = 1$ and therefore, $B = \frac{1}{\sin 1}$, and thus hence $y = \frac{\sin x}{\sin 1}$, so that's how we obtain. So, this $y = \frac{\sin x}{\sin 1}$ is the function which will optimize this functional, whether it will minimize or maximize that will be subsequently seen, we will have sufficient conditions to determine whether an external actually minimizes or maximizes.

Now, the second example is $I(y) = \int_0^1 y'^2 + xy dx$ and $y(0) = 0$ and $y(1) = 1$.

(Refer Slide Time: 34:21)

Example 2

$$I(y) = \int_0^1 [y'^2 + xy] dx$$

$$y(0) = 0, \quad y(1) = 1.$$

$$F(x, y, y') = y'^2 + xy.$$

$$F_y - \frac{d}{dx} F_{y'} = 0 \Rightarrow x - \frac{d}{dx} (2y') = 0$$

$$\text{or } x - 2y'' = 0$$

$$\text{or } y'' = \frac{x}{2} \Rightarrow y' = \frac{x^2}{4} + A$$

$$\Rightarrow \text{an } y(x) = \frac{x^3}{12} + Ax + B.$$

$$y(0) = 0 \Rightarrow B = 0, \text{ so } y(x) = \frac{x^3}{12} + Ax$$

$$y(1) = 1 \Rightarrow 1 = \frac{1}{12} + A \Rightarrow A = \frac{11}{12}.$$

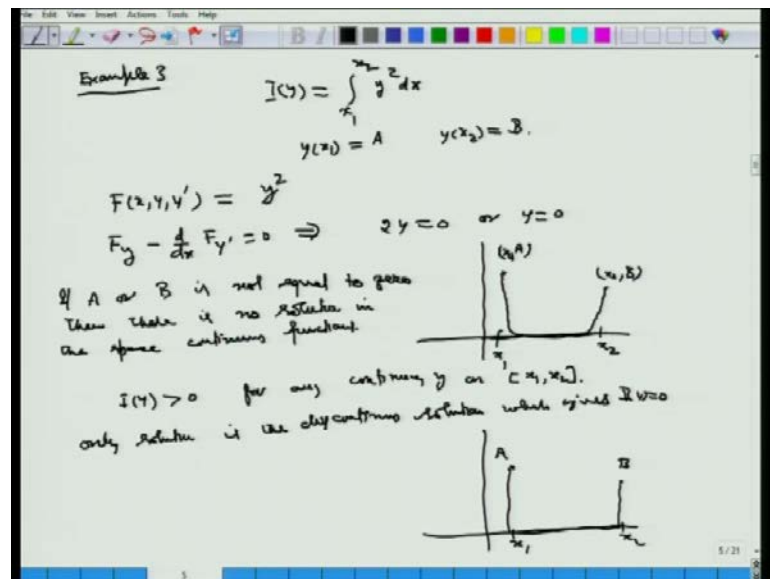

$$\text{Hence } y(x) = \frac{1}{12} (x^3 + 11x).$$

So, in this example now, comparing it with the standard form you see that integrand is so this is $F(x, y, y')$ is function is $y'^2 + xy$. And so Euler's Equation $F_y - \frac{d}{dx} F_{y'} = 0$ implies F_y is x here $- \frac{d}{dx} (2y') = 0$ or $x - 2y'' = 0$ or $y'' = \frac{x}{2}$, so this

implies y' equal to x^2 by f 4 plus A and then y of x equal to x^3 by 12 plus A x plus B .

So, now this A and B are to be determined using the given conditions, so $y(0) = 0$ implies that $b = 0$ and, so y is x^3 by 12 plus A x , now $y(1) = 1$ implies that $1 = 1$ by 12 plus A also implies that, $A = 11$ by 12 hence, $y(x) = 12x^3 + 11x$. So, that is the external given here, now the next example we consider here $I(y)$ is $\int_{x_1}^{x_2} y^2 dx$ rather x_1 to x_2 we are using, x_1 to x_2 integral $y^2 dx$ and conditions are $y(x_1) = A$ and $y(x_2) = B$.

(Refer Slide Time: 37:16)

Now, here F is x, y, y' is simply y^2 . So, the variables x, y had y , only variable y is present and x and y' are absent in this. So, we have Euler's Equation $F_y - \frac{d}{dx} F_{y'} = 0$ implies that $2y = 0$ or $y = 0$. So that means, x axis is the solution of this Euler's Equation and if, so here section is like this only this x axis is the here this is x_1 , this is x_2 . Now, if A and B are not 0, if A or B is not equal to 0 then there is no solution in the space of, in the space of continuous functions.

So, if our admissible class is the space of continuous functions on the interval x_1 to x_2 then there is no solutions here, because this if let us say both x_1 and x_2 are not 0, if both A and B are not 0, so this is x_1, A, A and this is that the somewhere here x_2, B and you see that here it cannot pass through these two points, because y is identically 0 here, so $y = 0$ for all x , so this is the candidate for optimizing the functional I and even if we

try to take approximation here like this, but it will never be 0 it can be reduced I can be reduced as much as we want, but 0 cannot be made here, for any y here this will be I y will be positive for any continuous y, y on x 1, x 2 and only solution is the discontinuous solution, is the discontinuous solution which gives you the, which gives I y equal to 0 that is following, so this is x 1 is x 2 and here is A and here is B, so this simply drops like this and goes like this and, so that is a discontinuous solution here (Refer Slide Time: 40:45). So, in this case there is no solution in this case of continuous functions.

(Refer Slide Time: 42:16)

example 4 $I(y) = \int_{x_1}^{x_2} [M(x,y) + N(x,y)y'] dx$

$F(x,y,y') = M(x,y) + N(x,y)y'$

$F_y - \frac{d}{dx} F_{y'} = 0 \Rightarrow$

$M_y + N_y y' - \frac{d}{dx} (N_x y') = 0$

$M_y + N_y y' - N_x - N_{y'} y' = 0$

$M_y - N_x = 0.$

A solution of this is a curve, which may pass through (x_1, y_1) & (x_2, y_2) . No solution in general.

η $M_y - N_x \equiv 0$ then $M dx + N dy = 0$ is exact

$\therefore I(y) = \int_{x_1}^{x_2} [M dx + N dy] = \int_{x_1}^{x_2} dU(x,y) = U(x_2, y(x_2)) - U(x_1, y(x_1))$

Now, the next example is, if you consider I y equal to x 1 to x 2 here some function M x y plus N x y, y prime d x, so here F x, y, y prime is actually equal to M x y plus N x y, y prime. So, Euler's equation F y minus d by b x of F y prime equal to 0 implies M y plus N y y prime minus d by d x of N x y here all these are functions of x, y equal to 0.

So, that this M y plus N y y prime minus, now this is total derivative of N x y, so first gives you N x minus N y y prime equal to 0, so this cancels here, so we get M y minus N x equal to 0. Now, here this gives a curve and if it does not pass through the points x 1 to x 2. So, solution of this **this** is an algebraic equation in x and y, and so this curve which may not pass through x 1, y 1 and x 2, y 2; if the pass also then there is a only 1 curve and this is not a problem of optimization in this case, and if so no solution in general if M y minus N x is identically 0, then this reduces to an identity then we see that that M d x plus N d y equal to 0 is exact and then I y is x 1 to x 2 M d x plus N d y and this. So,

there exist then some function of x y since it is exact, so therefore, this will be some function u existing such that, $M dx$ plus $N dy$ is equal to the total derivative of u of this x y here, and so this is at the value u at x_1, x_2 at y at x_2 minus u at x_1 y at x_1 and so this is a fixed quantity, a fixed quantity. So, therefore, in this case also it is not a problem of optimization, it is not a problem of the calculus of variations.

(Refer Slide Time: 46:49)

$$I(y) = \int_0^1 (y^2 + x^2 y') dx$$

$$y(0) = A, \quad y(1) = B.$$

$$F = y^2 + x^2 y'$$

$$F_y - \frac{d}{dx} F_{y'} = 0 \Rightarrow 2y - 2x = 0 \Rightarrow y = x$$

If $A \neq 0$ or $B \neq 1$
 then no solution.
 If $A = 0, B = 1$ then
 only we have $y = x$ gives the optimal value of I .
 If we have

$$I(y) = \int_0^1 (y^2 + x^2 y') dx \quad y(x_0) = A, \quad y(x_1) = B$$

$$F = y^2 + x^2 y', \quad F_y - \frac{d}{dx} F_{y'} = 0 \Rightarrow 1 - 1 = 0 \text{ which}$$

For example, if you take, if we have the lecture in this case $I = \int_0^1 y^2 + x^2 y'$ and $y(0) = A$ and $y(1) = B$, then in this case we have F as $y^2 + x^2 y'$ and $F_y - \frac{d}{dx} F_{y'} = 0$ implies that $2y - 2x = 0$, so implies $y = x$. So, this line $y = x$ is the candidate for this optimizing this functional and if $A = 0$ or if $B = 1$ then no solution (Refer Slide Time: 47:49). So, and if $A = 0$ and $B = 1$ then only we have $y = x$ as the candidate, x gives the optimal value of I .

Now, if we have $I = \int_0^1 y^2 + x^2 y'$ and $y(x_0) = A$ and $y(x_1) = B$. Now, in this case we have $F = y^2 + x^2 y'$, so $F_y - \frac{d}{dx} F_{y'} = 0$ implies that $1 - 1 = 0$ which is an identity, so we get the identity here hence which is an identity.

(Refer Slide Time: 50:48)

$$\begin{aligned} \text{that } I(y) &= \int_{x_1}^{x_2} (y + xy') dx = \int_{x_1}^{x_2} d(xy) = xy \Big|_{x_1}^{x_2} \\ &= x_2 y(x_2) - x_1 y(x_1) \\ &\text{or fixed quantity.} \end{aligned}$$

Now, we see that we observed that, that this $I(y)$ equal to x_1 to x_2 we can write it this y plus $x y'$ dx can be written as x_1 to x_2 d of xy here and so this is actually xy evaluated, xy evaluated at x_1 to x_2 , so this is x_2, y at x_2 minus x_1, y at x_1 and **which is in an** which is fixed quantity, a fixed quantity here.

So, this is not a problem of optimization, so like this there are many problems which although appear as optimizing problem, but as problem of calculus of variations, but they are not, so we will actually take the genuine cases of such problems in the next lecture, thank you very much for viewing.
