**Reparameterisation.**

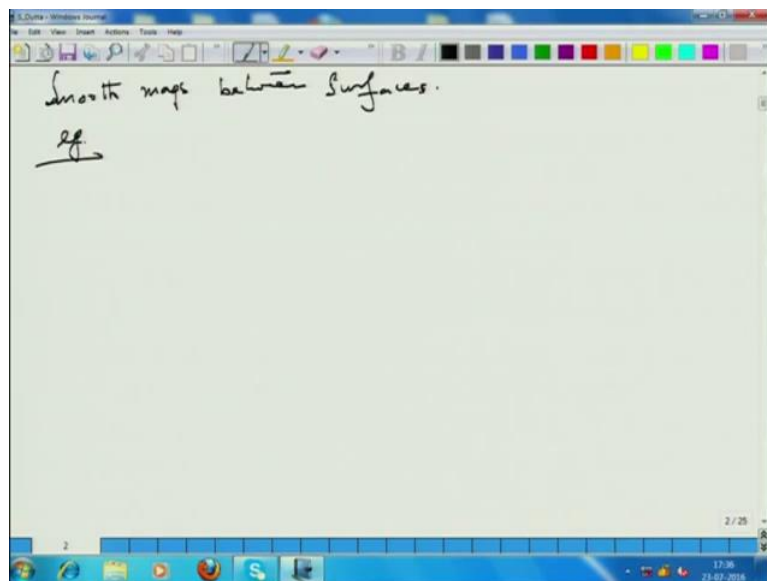

(Refer Slide Time: 0:25)

Welcome to the 3<sup>rd</sup> lecture, so let us recall what we have observed in the last lecture. 1<sup>st</sup> of all if I have surface patches  $\sigma$  from  $U$  to  $\mathbb{R}^3$  and I have another open set  $\tilde{U}$  and we have a bijective smooth map with smooth inverse, then  $\tilde{\sigma} = \sigma \circ \Phi$  is a reparameterisation of  $\sigma(U)$ . This was the 1<sup>st</sup> observation we made, we did not prove it, as I said the proof will be posted and the 2<sup>nd</sup> observation was that about the transition maps. That I have surface  $S$  in  $\mathbb{R}^3$  which is regular and smooth, we will all be, all we will be dealing with smooth surfaces.

I have  $\sigma$  from  $U$  to  $S \cap W$ , you can look back at the definition in the 1<sup>st</sup> lecture. And  $\tilde{\sigma}$  from let us say  $\tilde{U}$  to  $S \cap \tilde{W}$ , then I have this map  $\Phi$  which is from  $\tilde{U}$  to  $U$  where  $V$  is this  $S \cap W \cap \tilde{W}$ ,  $\tilde{V}$  is  $S \cap W \cap \tilde{W}$ , so this map is transition maps which is smooth, bijective and smooth inverse. By these 2 observations, we have decided that properties of smooth surfaces are modulo reparameterisation.

(Refer Slide Time: 04:05)

So, what about properties we define for the surfaces in  $R^3$ ? It is up to reparameterisation, so it should be true on the reparameterisation. So, with that idea, let us define smooth maps between surfaces. As usual, I will start with an example.

(Refer Slide Time: 4:24)

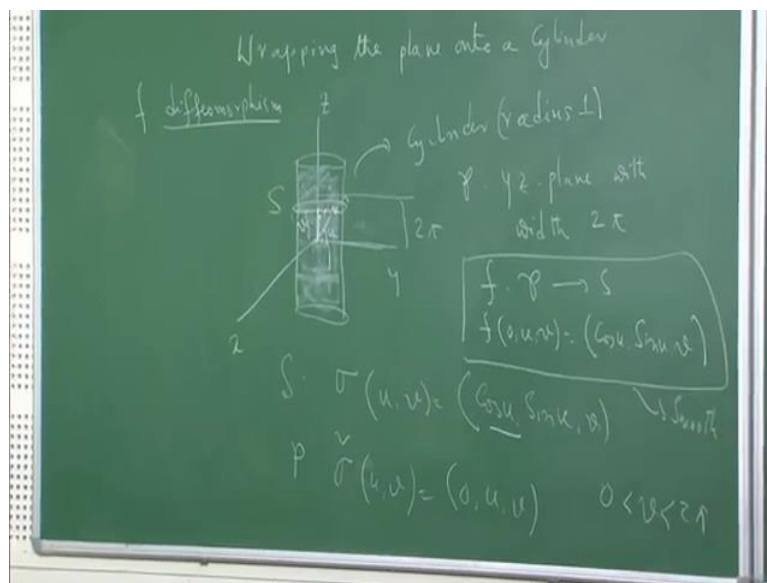

My example is, 1<sup>st</sup> example is wrapping the plane onto a cylinder smoothly. So, I take this cylinder, this is my z-axis, this is the cylinder, radius 1, okay. And I take the plane, so this is S, this is the surface of the cylinder. I take the plane P, it is a YZ plane with, not the entire YZ plane but  $2\pi$ .

Now, what I am doing, here I have the cylinder, I have the plane out here, I am trying to wrap this plane onto the cylinder smoothly. Now, as you know, as you can see very easily, this can be parameterised by single surface patch that is  $\cos U \sin U V$ , a typical point on cylinder is, this is the height  $V$  and this is the angle  $U$ . We will draw it little bit carefully, so, a point here, this is the height  $V$  and the angle  $U$ , so this is, this point can be uniquely determined by  $\cos U \sin U$  and the height  $V$ .

Now how is the  $YZ$  plane is parameterised?  $YZ$  plane is parameterised by  $\tilde{\sigma}(U, V)$  is  $(0, U, V)$ . Now if I try to wrap it, what will happen?

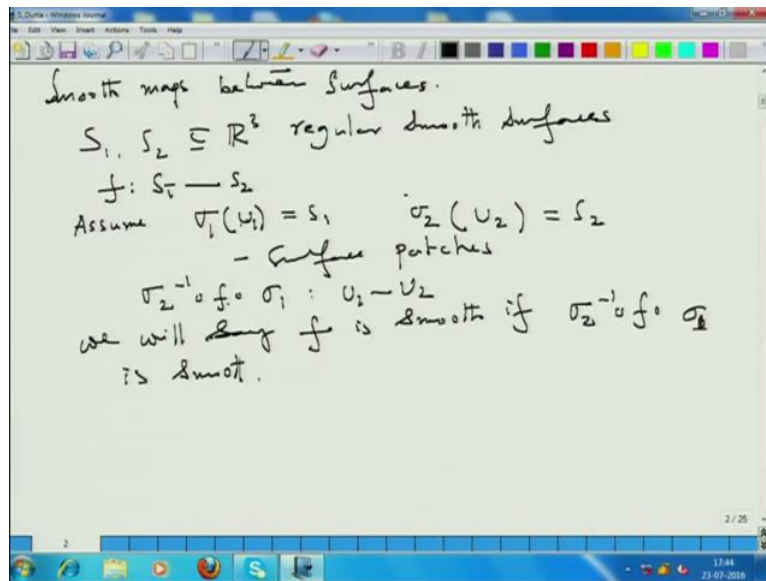

(Refer Slide Time: 7:22)

So, you immediately understand that this point will go to, so this particular point which is at angle  $U$  with  $YZ$  plane, that will be mapped into this point and according to, so  $V$  is between  $0$  to  $2\pi$  and that means the  $V$  coordinate will map to the height of the point. So, I can define the map if... Of, maybe I will write here or, okay let me write it on the board itself.

$f$  from  $f$  of  $0$  in  $V$  is  $\cos U \sin U V$ . You can check this  $f$  is a smooth map in the sense that all these partial derivative exist in a continuous, all partial derivatives all of them exist and continuous. Actually  $f$  inverse also exist and this  $f$  is actually a so-called diffeomorphism, what is a diffeomorphism, it is a homeomorphism with which is smooth, that means all its partial derivatives exist, partial derivative all exist. So, we will try to remember this example that such a way you can generate smooth map between surfaces.

(Refer Slide Time: 9:38)

So, in general while defining, let us make things little formal that suppose I have surfaces  $S_1$  and  $S_2$  regular smooth surfaces, so I have map from  $F$  from  $S_1$  to  $S_2$ . Assume  $S_1$  is covered by, okay let us say  $\sigma_1$ , single surface patch does not matter, otherwise you can always go back locally. And  $S_2$  is covered by and  $\sigma_2$ , so these are surface patches. Then I have a map,  $\sigma_2$  inverse compose  $F$  compose  $\sigma_1$ ,  $\sigma_1$  takes  $U_1$  to  $S_1$ ,  $F$  takes  $S_1$  to  $S_2$ ,  $\sigma_2$  inverse takes  $S_2$  to  $U_2$ . So, this is from  $U_1$  to  $U_2$ .

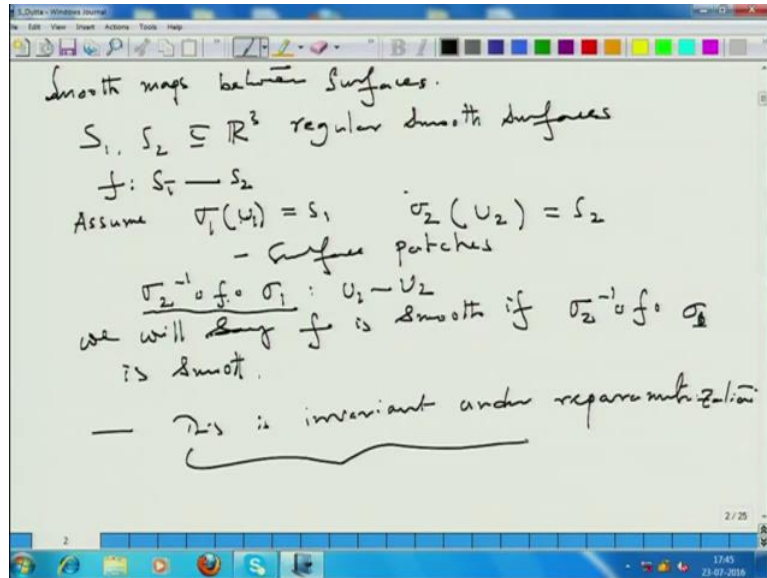

(Refer Slide Time: 11:30)

So, we will say  $F$  is smooth if this map is smooth For example here I have a plane at  $P$   $S_1$ , my other surface  $S_2$  is the surface of the cylinder, this  $F$  is smooth, then provided  $\sigma$  tilde

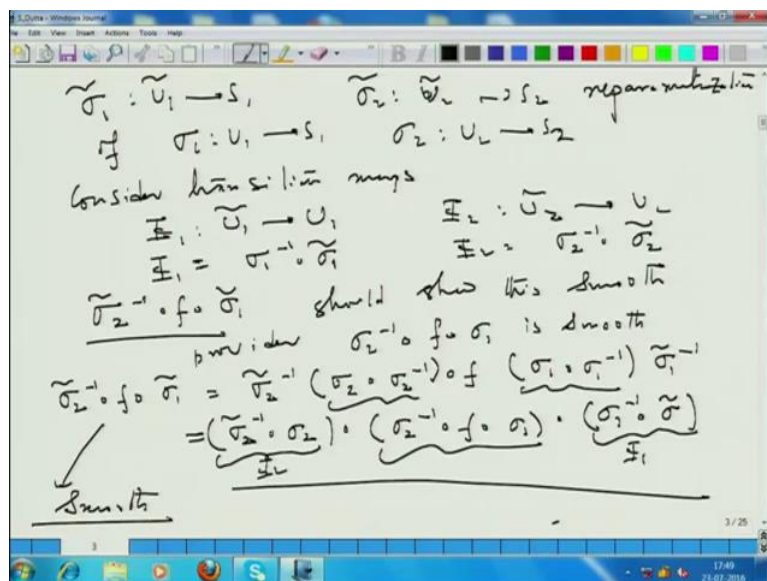

inverse  $F$  compose  $\Sigma$  is smooth but here it is trivial map,  $F$  itself. So, this is an example of smooth map.

(Refer Slide Time: 12:10)

So, this is, this definition is invariant under reparameterisation, that is the way we have done it, right. And looking about it, if I have this  $S_1$  and  $S_2$  are same, then under reparameterisation map will be smooth if for every reparameterisation  $\Sigma_1$  and  $\Sigma_2$  it is this mode.

(Refer Slide Time: 12:45)

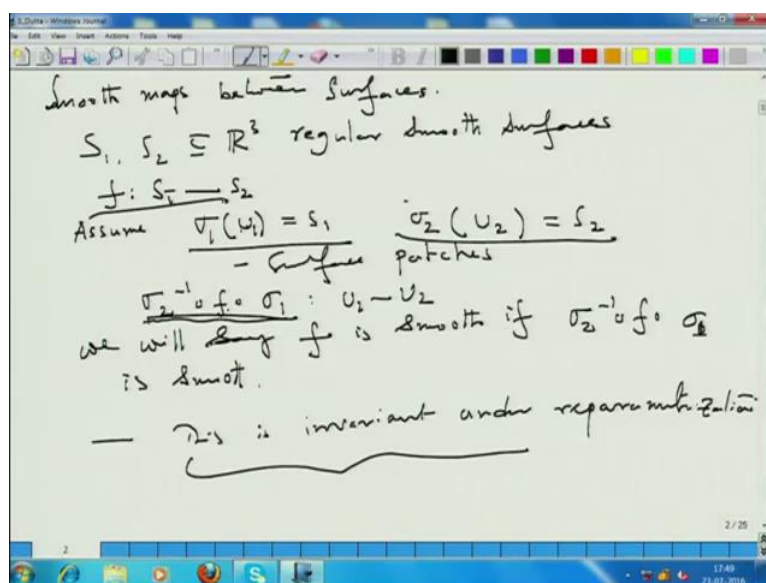

I mean, to illustrate this point, maybe we will look at  $\Sigma_1$  from  $U_1$  to  $S_1$ ,  $\Sigma_2$  from  $U_2$  to  $S_2$ ,  $\Sigma_1$  tilde  $\Sigma_2$  tilde  $U_1$  tilde  $U_2$  tilde reparameterisation of whatever we

have done in the earlier page.  $\Sigma_1 \cup U_1$  is  $S_1$ ,  $\Sigma_2 \cup U_2$  is  $S_2$ , suppose if I have 2 reparameterisation,  $\tilde{\Sigma}_1$  of  $\Sigma_1$  and  $\tilde{\Sigma}_2$  of  $\Sigma_2$ . Then consider transition maps  $\Phi_1$  from  $U_1$  to  $U_2$  and  $\Phi_2$  from  $U_2$  to  $U_1$  as usual is given by  $\Sigma_1$  which one,  $\Sigma_1 \cup U_1$  to  $\Sigma_1$  inverse compose  $\tilde{\Sigma}_1$ ,  $\Phi_2$  is  $\Sigma_2$  inverse  $\tilde{\Sigma}_2$ . Then you consider  $\Sigma_2$  inverse compose  $\tilde{\Sigma}_2$  compose  $\Phi_1$  compose  $\Sigma_1$  tilde.

What I should show? I should show this map is smooth provided, so should show this is smooth provided  $\tilde{\Sigma}_2$  inverse compose  $\Phi_1$  compose  $\Sigma_1$  is smooth. That was an previous page, right. Okay, what the big deal here? After all  $\tilde{\Sigma}_2$  inverse compose  $\Phi_1$  compose  $\Sigma_1$  tilde, I can write it as  $\tilde{\Sigma}_2$  inverse, I can put in  $\Sigma_1$  to compose  $\Sigma_2$  inverse which is identity compose  $\Phi_1$  and before  $\Sigma_1$  I can put  $\Sigma_1$   $\Sigma_1$  inverse  $\tilde{\Sigma}_1$  inverse, these 2 maps identity, right because they are homeomorphism. So, what will happen? This is  $\tilde{\Sigma}_2$  inverse compose  $\Sigma_2$  compose with  $\Sigma_2$  inverse compose  $\Phi_1$  compose  $\Sigma_1$  compose with  $\Sigma_1$  inverse com compose with  $\Sigma_1$  inverse tilde.

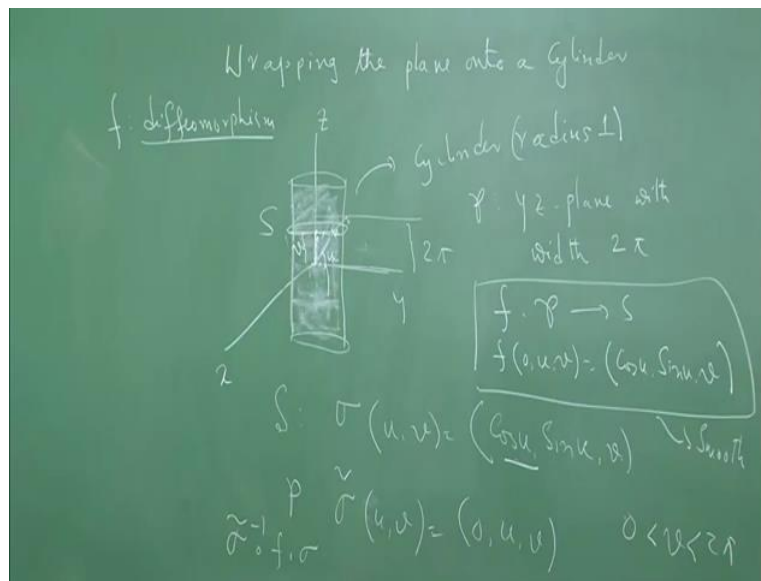

Now, the transition map, we have done a theorem, transition map of smooth surfaces are smooth. So, these are transition maps, this is smooth, these are smooth, this is  $\Phi_1$  and  $\Phi_2$ , this is  $\Phi_2$  and this is  $\Phi_1$ , they are smooth, this map is smooth and composition of smooth maps are smooth, so this map is smooth.

(Refer Slide Time: 16:40)

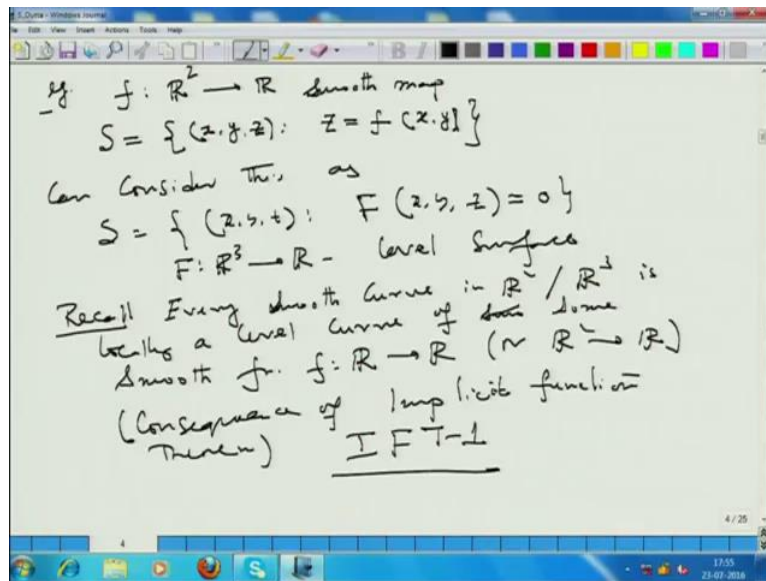

So, whatever you have defined the concept of a smooth function between 2 surfaces is invariant under reparameterisation. Is it clear? Just look at it once again, I will have one-minute pause, look at the 2 pages together and understand what they are trying to say, that any, for idea is whatever we define on surface, property of a surface, it has to be, the property has to be invariant under reparameterisation because I change, property changes in reparameterisation, then you cannot delete that property.

(Refer Slide Time: 17:24)

So, to illustrate that, we had this example of wrapping the plane on the cylinder smoothly and to make it formalised, we have done what is called as the smooth map between surfaces in general, this example in mind. And here we have shown that actually what we are seeing that these maps are, the property of the smooth maps between 2 surfaces, the definition is invariant under reparameterisation.

(Refer Slide Time: 18:02)

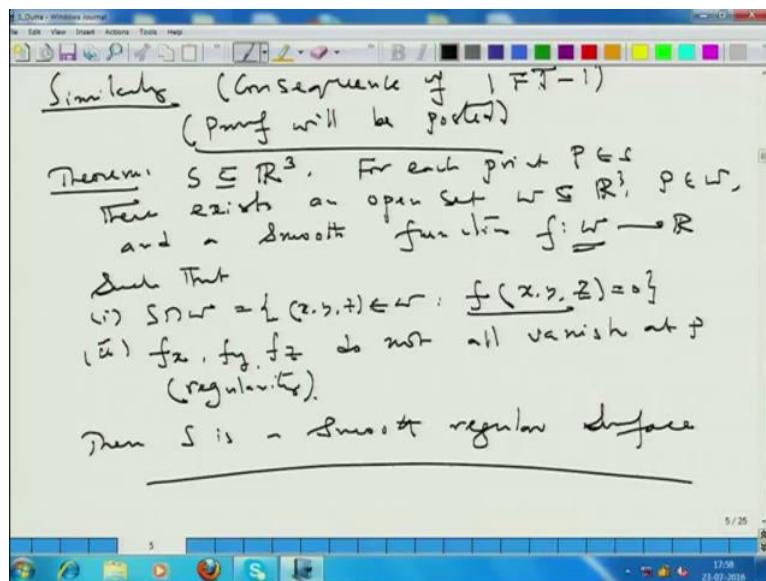

Now, this example we have done in the beginning that if I have, if from  $\mathbb{R}^2$  to  $\mathbb{R}$  a smooth map and if I look at the level surface of this graph, I think I denoted it by GF last time, level surface  $Z$  equal to  $FXY$ . You can also consider this as changing  $F$  is equal to 0, now  $F$  from  $\mathbb{R}^3$  to  $\mathbb{R}$ . So, this is a level surface. Now, if you recall for curves, a lecture in our last week lecture, every curve we realise as locally as level curve. So, recall every smooth curve in  $\mathbb{R}^2$  or  $\mathbb{R}^3$  is locally a level curve of some function  $\mathbb{R}^2 \rightarrow \mathbb{R}$  or  $\mathbb{R}^2 \rightarrow \mathbb{R}$  as the case may be. And this was consequence of implicit function theorem. Right.

Which I usually denote as IFT 1, in my previous NPTEL note, if you go to the portal, you will find that there is a post on IFT 1 and IFT 2, implicit function theorem and inverse function theorem.

(Refer Slide Time: 20:57)

On a similar line, similarly, this is again consequence of IFT 1, implicit function theorem, proof will be posted, do not worry too much about the proof because that is not going to be what you need for the course. And this course is unto learn certain basics about the curves and surfaces. So, this proof is not important for the course.

The theorem we have here, it says that, okay, locally again, every surface is a level surface. So,  $S$  in  $\mathbb{R}^3$ , let for each point  $P$  in  $S$ , there exists an open set an  $\mathbb{R}^3$  containing that point. And a smooth function such that  $S$  Intersection  $W$  is actually the level surface for this and for regularity purpose, so this is the regularity part, then  $F$  is a smooth or regular smooth or smooth regular surface.

Okay. So, this is the direct consequence of implicit function theorem. And this is also a way how you construct a surface. That is, okay, I choose open sets around  $W$  certain  $(\ )$ (24:01), I construct the patches of the surface by this, taking a smooth function  $F$  and look at, taking a smooth function and look at the living set of that function  $F$  and I put the patches together, then I will get a smooth regular surface. So, next time in the next lecture I will show you how torus, we have discussed about torus, the example of torus is there in the assignment also, how torus can be realised as a level surface of some smooth function  $F$ . So, that is in the next lecture, thank you.
