Lecture - 25
Multiple Integral

So we are here in the last lecture of the fifth week. So if you look back, it is time to take a look back and if you take a look back, you will realize that we have covered a lot of ground. All the lectures might not be in tremendous detail, but we have made considerable amount of progress. This section is about using the method of substitution that we use in your single variable calculus and integration.

Does that method have any role, that kind of methods have any role when you have more than one variable? Sometimes changing variables makes life easier. For example, the book gives a simple example which say which if I give to anyone, anybody will do it.

(Refer Slide Time: 01:10)

The slide contains handwritten mathematical notes and a diagram. At the top, a substitution problem is shown: $\int_2^3 x \sin(x^2) dx = ?$ followed by $\Rightarrow \frac{1}{2} \int_4^9 \sin(u) du$. Below this, the substitution $x^2 = u, 2x dx = du$ is written. In the middle, the text "Change of variables in multiple integration" is written in blue. To the left of this text is a diagram of a 2D coordinate system with x and y axes. A point (x, y) is shown in the first quadrant, and its polar coordinates (r, θ) are indicated. A vector r is drawn from the origin to the point. Below the diagram, the equations $|r| = r$ and $\begin{cases} x = r \cos \theta \\ y = r \sin \theta \end{cases}$ are written. To the right of the diagram, the text "(r, θ) → polar coordinates" is written. Below this, the double integral $\iint_W f(x, y) dx dy$ is shown, followed by $\tilde{f}(r, \theta) = f(x \cos \theta, r \sin \theta)$. At the bottom right, the transformation $W \rightarrow W^*$ and the question $dy dx = ??$ are written.

So if I have to evaluate it, this kind of integral, so we are going to talk about, so what are what am I supposed to do? How do I evaluate it? What I do is I will put x^2 is equal to u and I know to $2x dx$ where $2x$ is the derivative of this is du . So du is $2x$, so $2x dx$ is du . So basically, what you do $x dx$ is then half of du , so, the whole thing gets changed. So when x is 2 u is 4 and then when x is 3 u is 9.

So it is $\sin u$ half du . And then you can integrate it. You know what to do, it is $-\cos u$. So how will this substitution work when we have more than one variable. So if you have two variables x and y , how does this idea of substitution work. So this brings up us to this new chapter or new topic change of variables in multiple integration. There are two popular ways of identifying points on the plane $\mathbb{R}^2$.

So these ways are following. Take a point which is given by the coordinate x, y . That is the Cartesian coordinate and if you observe this x, y this vector which we call r has a magnitude r that are r . Now this direction vector makes an angle θ with the x axis. So this r and θ can actually tell me where a point is located, because x can be, if you know basic trigonometry, you will know x can be expressed as $r \cos \theta$. This is your x and this part, this part is your y .

And y can be expressed as $r \sin \theta$. So this r, θ variables r, θ , they are often referred to as polar coordinates. So I can represent this point by r, θ called polar coordinates. Sometimes it is easier to integrate in polar coordinates than in the standard Cartesian coordinate system. So how will I integrate in terms of polar coordinates? First, suppose you have a region W and you are integrating.

So first you have to substitute in place of x and y r and θ , x is $r \cos \theta$ y is $r \sin \theta$. That is you have to construct a function $f(r, \theta)$, which is $f(x \cos \theta, y \sin \theta)$. In place of y it is $r \sin \theta$. And the domain W has to change to W^* . Domain W has to change to some W^* and then you integrate over the polar coordinates. Now here I have replaced for example, $dx dy$ is replaced with du .

Now here my elemental area $dy dx$ or $dx dy$ is replaced by what? What should it replace? Should be replaced by, what is that? What should replace $dy dx$ in this case? So we have to now first look at what is the meaning of an elemental area when you were talking about polar coordinates.

(Refer Slide Time: 07:04)

So elemental area polar coordinates, elemental area in terms of polar coordinates. So here I draw the x axis and I draw that y axis. Now let this be r, theta. Then you make a little bit of increment in r, this is dr. Now little increment in theta. So this was theta, so this is d theta.

So now my elemental area is this one and r is the radius. Since dr is very small I assume that this area this zone this line and this curve this the outside curve the outside arc means the inside arc means which is this one and outside arc which is this one they have they are almost of the same length, this kind of a rectangle though really it is not but we are assuming that it is.

What is the area what is the length of such a thing? That is r, s the rectangular the arc length is r into theta where theta is measured in radians. So if I measured theta in radians, theta is measured in radians. Theta is measured in radians. So if I am looking at this side or this side inner side, they are same. This is r, d theta and this little side is dr. So elemental area, elemental area is equal to r dr d theta.

So the idea is very simple. Replace dx dy with r dr d theta. So whatever was the elemental area there which was dx dy is replaced by the that elemental area should have a similar area which is r dr d theta. That is the elemental area, area of elemental area is calculated, both are da basically. They represent da. So what happens is, so in terms of the polar coordinates, so $\iint_W f(x, y) dx dy$ is equal to $\iint_{W^*} f(R \cos \theta, r \sin \theta) r dr d\theta$.

Elemental area is actually maybe I should write it much more is $r dr d\theta$. This angle $d\theta$ into radius. That is the arc length then into dr . So which I can write as is preferably written as $r dr d\theta$. So this is what I have where W star is the corresponding zone. For example, if I take W is a set of all x, y such that $x^2 + y^2 \leq a^2$. So it is a circle with center at the origin.

This is your W . Well what is my W star? $x^2 + y^2 \leq r^2$. So r squares is r here is a is positive so r is less than equal to a . So r has to lie between zero and a , r is a positive r^2 is a positive number. In terms of x and y , so θ is varying from zero to 2π . θ is free here. So my W star would consist of $r d\theta$ because r is non-negative. Here $r^2 \leq a^2$, $r \leq a$.

Where r must be here. And θ must be between zero to 2π . So basically if I draw the x axis and y axis by putting r in one r in this side, and θ in this side. So r and θ , so if this is 2π and this is a then it is a kind of rectangular box. So you see what is this transformation doing to this region, that a rectangular box has changed over to a rectangular box.

Sorry a circular region has changed over to a rectangular box and you know how to integrate over a rectangular box, the same kind of integration, that you have done. As an example, we use our knowledge here, what we have just done to understand how to compute.

(Refer Slide Time: 14:09)

$\iint_W \log(x^2 + y^2) dx dy$

W is the region in $\mathbb{R}_+^2$ lying between the circles $x^2 + y^2 = 1$, $x^2 + y^2 = 4$

$1 \leq r \leq 2$
 $0 \leq \theta \leq \frac{\pi}{2}$

$\iint_W \log(x^2 + y^2) dx dy$
 $= \int_0^{\pi/2} \int_1^2 \log(r^2) r dr d\theta$
 $= 2 \int_0^{\pi/2} \int_1^2 (\log r) r dr d\theta$
 $= \frac{\pi}{2} \left[4 \log 2 - \frac{3}{2} \right]$

This is an example from the book. Please understand that we are continuing to use this book. Those who have not seen this book, again I want to show it. Please see that this is the book that I am using. It is called basic, Basic Multivariable Calculus by Jerrold Marsden, Anthony J. Tromba and Alan Weinstein, Basic Multivariable Calculus. This is exactly what I have been using throughout.

I maintained a single text, which is much more easier when these kind of subjects were, this particular subject where lot of practice is needed to get used to a method. So there goes a story of John von Neumann who is one of the world's greatest mathematicians of the 20th century. And John von Neumann has this story that there was a physics student in Princeton, and he got stuck with a PD, which his supervisor could not even solve, okay.

So then he told his student that why do you not go to John von Neumann and ask him. Finally he found John von Neumann in party dancing around and he showed the problem to John von Neumann and John von Neumann told him use the method of characteristics. So he goes back and tries to find what is the method of characteristics in solving the particular equation, partial differential equation.

And then he goes back and then meets Neumann and says that I have used that method of characteristic, and I have actually solved the problem, but I do not really understand what is the method of characteristic. So von Neumann told him, my son, you do not always understand things in mathematics, you just get used to them. So it

is time that we also here in these kind of subjects for what we are doing now, we need to get used to things. So a single book and certain standard examples do help.

For example, this example where W is the region in $\mathbb{R}^2$ plus and that is in the first quadrant lying between the circles $x^2 + y^2 = 1$ and $x^2 + y^2 = 4$. So it is circles with radius 1 and radius 2. So if you draw the thing you just need to concentrate on the circle of radius 1 and circle of radius 2. So this is the zone that you are bothered with. So R is lying between 1 and 2.

In this case, if you look at the polar coordinates, this is radius here is 1 and radius is 2. So R is lying between 1 and 2 and θ is lying between 0, angle could be 0 or it could be $\pi/2$. So 0 to $\pi/2$. So you see again you have converted this so called domain W , this domain W had been converted into a, domain W has been converted into a domain W^* which is rectangular in nature, where your iterated integration will work.

So your area is 0 to $\pi/2$, for example this is $\pi/2$. So this is now your zone, exists between r is between 0 to 1, 1 over x axis for example. The horizontal part is between 0 to 1. This part is between so this part is my W^* . So now it has become a rectangular one. Now, you can easily use this transformation to compute out stuff. So let us take ourselves into the next step.

So the integral of $W \log(x^2 + y^2) dx dy$, so r is running from our $r dr d\theta$. So r is running from 1 to 2 and this is varying from 0 to $\pi/2$. And so you can use the iterated integral technique. $x^2 + y^2$ is r^2 $r dr d\theta$. So you know that this is nothing but $2 \int_0^{\pi/2} \int_1^2 \log r r dr d\theta$. So we integrate out this finally, I am not doing the integration completely.

The answer turns out to be $\pi/2$ into $4 \log 2$ minus $3/2$. You see so this change of variable has made a slightly difficult looking domain transform into a much more easier looking domain and you can solve the problem by the method of iterated integration. The goal is to solve these by the method of iterated integration. You can come to triple integrals. In triple integrals, we are talking about cylindrical coordinates.

(Refer Slide Time: 21:02)

For triple integrals we have coordinates

$$(x, y, z) \rightarrow (r, \theta, z)$$

$$x = r \cos \theta$$

$$y = r \sin \theta$$

$$z = z$$

Elemental volume := $r dr d\theta dz$

Replace $dy dx dz$ by $r dr d\theta dz$

$$\iiint_W xyz dx dy dz$$

$$W = \{(x, y, z) : x^2 + y^2 \leq 1, 0 \leq z \leq x^2 + y^2\}$$

$$W^* = \{(r, \theta, z) : 0 \leq r \leq 1, 0 \leq \theta \leq 2\pi, 0 \leq z \leq r^2\}$$

Just like polar coordinates, when it comes to triple integrals, we have cylindrical coordinates that is, for x and y we write it as a polar coordinate. Other parts we keep as z , cylindrical coordinates. That is we move from x, y, z to r theta z . We move from x, y, z to r theta z . So in that case here you write x is equal to $r \cos \theta$, y is equal to $r \sin \theta$ and z becomes equals to z .

And here the elemental volume in this case is given as our $r dr d\theta dz$. So we have to replace $dy dx dz$ replace by $r dr d\theta dz$. So in the same way you can operate on this. For example, if you want to evaluate that this is an example here in the book. If you want to evaluate say, so here one has to understand, we can put a restrictions on x , y and also on z . So for example here we will integrate over W .

We will say what is it, xyz into $dx dy dz$ where the W domain is consisting of triplets of point x, y, z in $\mathbb{R}^3$ such that $x^2 + y^2 \leq 1$. So it is a circular region and z , so z is lying between 0 and $x^2 + y^2$. So what do we do? So, you first take $x^2 + y^2 \leq 1$. That is the domain that is the domain what you have.

We are taking these points in $\mathbb{R}^2$. This is circle $x^2 + y^2 \leq 1$. Now, you are talking about the graph of $x^2 + y^2$. So here is the paraboloid. So take any point here, so this is my z point. So basically you are taking

any point here till you come here to till the end. So this is the volume that you are trying to compute. So basically you have converted into a cylinder.

So it is not the volume you are trying to compute. You have converted the converted the zone into a cylinder. It looks like a cylinder. So let us see what W star consists of. So W star when I transform it, it consists of r θ z where r is lying between 1 and 0, θ is lying between 0 and 2π . And then z is lying between 0 and $x^2 + y^2$ which is your r^2 , same as r^2 .

You take any xy , $x^2 + y^2$ circle is equal to r^2 . So this length is exactly, if you take this is your $x^2 + y^2$ value, this is exactly this length, this square type, so is a square. So z is lying between zero and $x^2 + y^2$. So now your domain has changed from x, y, z to r, θ, z . So that is a cylinder. That is a cylinder that has been made.

So now here you have converted into a cylinder. Now what will you do? You will again do sorry not the cylinder the cylinder coordinates what, I am making a mistake. So here what you see, you have a cylindrical thing. So when you convert the cylindrical, this is in x, y, z plane in x, y, z space you have the cylindrical domain. But cylindrical domain you cannot operate on.

By making a cylindrical transformation with cylindrical coordinates this W star has become now a rectangular parallelepiped. It is a kind of domain that you have already used, kind of domain that you have learnt in the triple integral. It is not rectangular parallelepiped, it is fixed with x and y . Only the z part is varying, right? x part and y part is fixed and the z part is varying.

And you know how to handle it using the things from the rectangle. You know how to handle it using iterated integral. That we already learnt in triple integral. So from this system of a cylindrical thing, we have come down to a one with much more simpler coordinates here.

One with r, θ where they are fixed and this one is varying and you know how to handle the varying case because we have already learnt it that okay, this region can be

put under a rectangle and this function can be defined to be zero outside this W star zone and so and so forth, which we have learnt.

(Refer Slide Time: 28:04)

The image shows a handwritten mathematical derivation of a triple integral over a region W. The integral is $\iiint_W xyz \, dx \, dy \, dz$. It is converted to spherical coordinates with the following steps:

$$\begin{aligned} \iiint_W xyz \, dx \, dy \, dz &= \int_0^{2\pi} \int_0^{\pi} \int_0^1 (r \cos \theta) (r \sin \theta) z \, r \, dz \, dr \, d\theta \\ &= \int_0^{2\pi} \int_0^{\pi} r^3 \sin \theta \cos \theta \frac{r^4}{2} \, dr \, d\theta \\ &= \int_0^{2\pi} \frac{1}{32} \sin 2\theta \, d\theta \\ &= 0 \end{aligned}$$

Below the equations is a diagram of a 3D coordinate system with axes x, y, and z. A point (x, y, z) is shown in the first octant. A vector r of length ρ is drawn from the origin to the point. The angle between r and the z-axis is θ, and the angle between the projection of r on the xy-plane and the x-axis is φ. The coordinates of the point are labeled as (x, y, z) and (x, y, 0). To the right of the diagram, the following equations are listed:

$$\begin{aligned} x &= r \cos \theta \\ x &= \rho \sin \phi \cos \theta \\ y &= \rho \sin \phi \sin \theta \\ z &= \rho \cos \phi \end{aligned}$$

Below these equations, it is noted that $(x, y, z) \rightarrow (r, \theta, \phi)$ are Spherical Coordinates.

So in this particular case we see we write like this. First we integrate this with respect to z. So here you will have $r \cos \theta r \sin \theta z$, $r \cos \theta r \sin \theta z$, $r \, dz$ then dr then $d\theta$. So after this when I integrate out z it will be in terms of r. So then we integrate from r is from 0 to 1 and where we have just we will be left with functions of theta integrated from 0 to 2 pi. That is the way you should do it.

And if you integrate this so will have $zr \, dz$. Now you integrate with respect to r sorry z first, so you have that only one z. So $r \cos \theta r \sin \theta$ remains constant and z you integrate out with so it will become z^2 by 2 and then you put r^4 and this r into r into this r will r cube, $r^3 \sin \theta r^3 \cos \theta$. So r^4 by 2 $dr \, d\theta$. Let me integrate the theta out.

So finally we will have 0 to 2 pi $\frac{1}{32} \sin 2\theta$. I will not go in the details of the computation. You can check in check the details yourself. That will give me finally the answer to be zero. So that is one way of it. There is something called spherical coordinates, which is also often used but we will just mention what is a spherical coordinate. Spherical coordinates come like this, this is how we describe spherical coordinates.

So if you have a point in x, y, z in space, so here is the distance that you know x, y, z . So angle so the angle of this line joining the origin, the lines have been joining the origin and x, y, z this angle it makes angle ϕ with the z axis and it makes an angle, suppose I put I drop a perpendicular from x, y, z to the x axis. So it gives me the point $x, y, 0$. Join that line with the origin and that new line makes an, which is r here makes an angle θ . So if you go at x , what is r , right. So what is x here?

So in this case x is equal to $r \cos \theta$. What is my r ? r if you look at it is equal to this. This is your r also. This is your r and this is nothing but $\rho \sin \phi$. So r equal to $\rho \sin \phi$. So $\rho \sin \phi \cos \theta$. Similarly, y can be written as $\rho \sin \phi \sin \theta$. Because that $r \sin \theta$ basically. And what is z ? z is nothing but $\rho \cos \phi$.

This is called the this three things this is the transformation from the Cartesian coordinates to $r \theta \phi$. This is called the spherical coordinates. So from x, y, z to $r \theta \phi$ is called as spherical coordinates. So we had a pretty decent idea of what kind of transformation we use largely in natural sciences. But now, we want to give you a more general mathematical description of how to do a transformation.

So that brings us to a very basic idea. For example, if you had this, if you have looked at this transformation, what we had studied when we were doing that single integral when you had looked at the transformation u equal to x square.

(Refer Slide Time: 33:31)

$$\begin{aligned}
 u &= x^2 \\
 du &= 2x \, dx \\
 \boxed{du = \frac{du}{dx} \cdot dx} \\
 &\downarrow \\
 &\text{differential of } u
 \end{aligned}$$

What is the analog in higher dimension

x & y are functions of u, v .

$$\begin{aligned}
 x &= x(u, v) \\
 y &= y(u, v)
 \end{aligned}$$

Determinant of the Jacobian

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix}$$

So what did you do? du is $2x dx$. So what is $2x$ that is du/dx . So that is the way transformation is done. du is nothing but du/dx into dx . But then how do I go do this thing in case of how do what is this is actually called the differential of u . This is actually if you linearize the function, if you just take the first order Taylor's expansion this is nothing but this changes the quantifying the value of u as x changes, this term du/dx into dx . That is all.

It actually quantifies the value when x is very small and hence u is very small, assuming they are all continuous because they are differentiable. So how do we speak about how do we do this kind of change of variables in higher dimensions? What is the analog in higher dimension? So what is the analog in higher dimension? So now suppose you have x, y are functions of u, v like x, y a function of r, θ , x is $r \cos \theta$, y is $r \sin \theta$.

So x, y suppose x and y are functions of u, v that x is $x(u, v)$ that is x is kind of $x(u, v)$. This is a one way of writing and y is $y(u, v)$. We compute what is called the determinant of the Jacobian. So we shall compute what is called the determinant of the Jacobian, determinant of the Jacobian. This is symbolically written like this. This is a symbol, it does not have any significance.

It is a determinant, it represents a determinant; so determinant of the Jacobian matrix. So what is the Jacobian matrix? So x, y is a function of from $\mathbb{R}^2$ to $\mathbb{R}^2$, right? So when you have a function from $\mathbb{R}^2$ to $\mathbb{R}^2$ the derivative of that function is a matrix called the Jacobian. So what you do? You first find the gradient of this first function $x(u, v)$ and put it as a row vector.

Then you find what is the gradient of the second function $y(u, v)$ and put it as a row vector. So $\frac{\partial x}{\partial u} \frac{\partial x}{\partial v}$. So these are so this is the determinants. So $\frac{\partial y}{\partial u} \frac{\partial y}{\partial v}$. This is a determinant. So what we can actually show that the following thing occurs.

(Refer Slide Time: 37:58)

$$\begin{aligned}
 u &= x^2 \\
 du &= 2x \, dx \\
 \boxed{du = \frac{du}{dx} \cdot dx} \\
 &\downarrow \\
 &\text{differential of } u
 \end{aligned}$$

What is the analog in higher dimension

x & y are functions of u, v .

$x = x(u, v)$
 $y = y(u, v)$

Determinant of the Jacobian

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{bmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{bmatrix} \rightarrow \text{Jacobian matrix of the transformation}$$

$$\det \frac{\partial(x, y)}{\partial(u, v)} = \left| \frac{\partial(x, y)}{\partial(u, v)} \right| = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix}$$

That we can show that integral some domain W . Same way you can go for three variables also, r^3 to r^3 but we are just concentrating on two variables. So now, you can have arbitrary, you need not have polar coordinates particular or you can have x is $u + v$ y is $u - v$, this kind of transformations also. So if you have this kind of thing. So this integral can now be given us W star f instead of x I have $x(u, v)$.

Instead of y I have the function of y as a function of u, v into the determinant $\det x, y$. So what we need is the determinant of so this is the Jacobian matrix. I first showed it as a determinant but let me just for not to make you uncomfortable, this is the Jacobean matrix.

First we compute, so this is the symbol a standardized symbol in multivariable calculus for the Jacobian when you are writing this transformation, Jacobean matrix of the transformation and determinant of $\det x, y \det u, v$ is written as $\det x, y \det u, v$ which is what we wrote earlier $\det x \det u, \det x \det y, \det y \det u, \det y \det v$, okay. I just made this change so that you do not get confused that I skipped it so much.

It does not matter even if I write this as the determinant, it does not matter. But people are much more concerned about particular signage and all those things. So determinant means something like this the matrix and then you compute the determinant.

(Refer Slide Time: 40:15)

$$\iint_W f(x, y) dx dy = \iint_{W^*} f(x(u, v), y(u, v)) \left| \det \frac{\partial(x, y)}{\partial(u, v)} \right| du dv$$

$$\iint_W (x^2 - y^2) dx dy$$

$$x = u + v$$

$$y = u - v$$

$$u = \frac{x+y}{2}$$

$$v = \frac{x-y}{2}$$

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$$

$$\det \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} = -2$$

$$\iint_W (x^2 - y^2) dx dy = \iint_{W^*} 4uv (-2) du dv = 8 \int_0^1 \int_0^1 uv du dv$$

$$= 2 \sqrt{6} \text{ (Note: This is likely a typo for } 2 \text{ in the original image) }$$

This into dudv. So you are replacing dx dy with this. This is the standard way of doing it. So you take a kind of transformation say you integrate W over x square minus y square dx dy. And let W be this given region. So it is a square with this vertices (0, 0) (1, 1) (2, 0) (1, -1). This is my W. Now let me look at W dash. So to compute W dash I need a transformation.

Let us put that the change of variables x is equal to u + v and y is equal to u - v. And from this transformation what happens? So you can actually calculate out u. So 2u here is x + y or u is x + y by 2. And v is x - y by 2. So you know when x is 0, 0 y is 0, 0. When x is 1, 1 x is 1 and y is 1. Then u is half, right? So when it is 2, 0 when x is 2 and y is 0. So when u is 0, 0 when x is 0, 0, that is my original thing.

Then I should have u as 0, 0. Now when x is 2 and y is 0 then u must become 1. And when x is 2 and y is 0, v also becomes 1. So 2, 0 gets shifted to 1, 1 right? So what is 1, 1? So anything so this 1, 1 was here in this zone that becomes 1, 0. That becomes a vortex here. So basically, this W star becomes this thing, W star becomes this rectangle with (0, 0) (1, 0) (1, 1) and (0, 1).

So similarly now we find we compute this. And you know, it is not a very difficult thing to compute. It is the jacobian is 1 1 1 -1. And determinant of this thing 1 1 1 -1 is equal to -2. So my integral of D, x square minus y square dx dy can be now written as x square minus y square is nothing but 4 uv, u + v whole square minus u - v whole square is my not D my W sorry, W to my W dash.

Where $\mathbf{W}$ is nothing but 0 to 1 , 0 to 1 4 uv . So what we do here, does have some little problem in the writing. I just make a correction here. I forgot to write the determinant. Determinant of $\det \mathbf{x}, \mathbf{y}$. I tell you take the positive part of absolute value into $dudv$. I forgot to write the determinant. So determinant is this. So you take the modulus of that minus 2 is 2 into $dudv$. So basically it is $8, 0, 1, 0, 1$ $dudv$ sorry $uvdudv$.

The answer turns out to be 2 . So as a French man would say *voila*, we are done, we have covered a good amount of ground and now that everything needs is you need to have practice. Once you have practice, you get a hold of these things, and you will never forget how to do these things. Just a little bit of practice. That is it. For me also, it is very good to sometimes to teach calculus because it gets you back to your basics.

Maybe you also if you have to get into some integrate calculation one is to go back and look at the basic books. But it is sometimes always good to teach the basics because then you remain in touch with it. So thank you very much. So we will start our sixth week very soon. And we will get into more applications, we will get into gradually get into surface integrals, line integrals, the Green's theorem, Stokes' theorem and divergence theorem and end of the game.

The last lecture would be more general where it is little more on fields. It will be largely on applications to physical sciences.
