Lecture - 26
Applications of Integration to Mechanics

Welcome to the sixth week of the course. So if you look at the course plan, if I go by the course plan, then there is this whole change of variable formula was supposed to be the first lecture of the sixth week, but we have already spoken about change of variable formula in the last class. So I think I will not bore you on that again. Rather this week, because I have already exceeded as per the norms, I have exceeded the number of hours by quite a heavy margin.

I do not know whether it is good or bad, but I have done that. So I think the sixth week will have four lectures, which will also I believe, would exceed the given fixed time of two and a half hours, 30 minutes, five lectures 30 minutes each, but we will start with the second one and we will have four lectures in this session, in the sixth week session.

That is multiple integral and mechanics, which I wrote as application of integration to mechanics. Line integrals 1, which we will do and then line integrals 2. These are two important things which we need to know to do further things about Gauss and Stokes theorem, line integrals would come; Gauss theorem, Green's theorem.

Then we will talk about parametrized surfaces, means how can we look at surfaces which cannot be viewed as functions $z = f(x, y)$. How can we view them mathematically. Can functions be used to represent them. So in that case we need to parametrize and that is what we will do here in this sixth week. So we will start today with application of multiple integrals.

See one application of multiple integral I have already told you is that of finding average temperature. In the last class, class before that when we spoke about triple integrals, we spoke about why triple integrals are needed. For example, we spoke about finding the average temperature in a, say a rectangular room. Now if you go

back to the notion of average, the notion of average plays a very fundamental role in mechanics.

The notion of average, for example, takes on important roles for determining things like center of mass, moments of inertia. So all these things has a notion of average. So average means summing up things and then dividing it by the number of things.

(Refer Slide Time: 03:00)

The image shows a handwritten slide with the title "Applications of Integration to mechanics". It contains two equations for the average value of a function. The first equation is $\langle f \rangle = \frac{\int_a^b f(x) dx}{b-a}$. The second equation is $\langle f \rangle = \frac{\iint_W f(x, y) dx dy}{\iint_W dx dy}$.

So in general if you have a continuous function, or even a bounded function and you want to integrate, then the average of a function, continuous function over a given interval, the integration represents a sum of the values divided by the total x's that you have, that is captured by the expression $b - a$. And this is often called the average of f and this symbol of average of f is something which I have borrowed from the physicist. Physicists use this sort of thing.

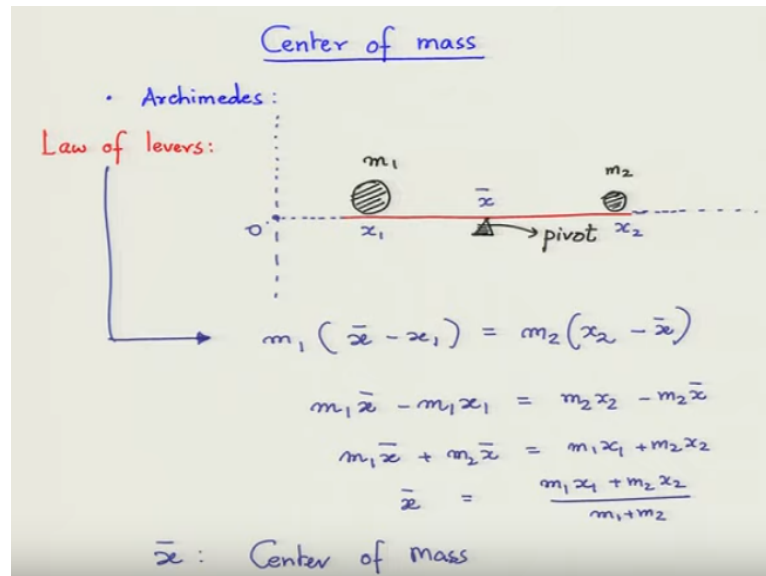

So what happens if I have a scenario where I have now an area to handle? That is two variable for when I am talking about functions of two variables, and I am talking about double integrals, then what I need, which way I can define the average and how can I generalize this idea that I already know. So again, I am just taking the same thing. Here my f is no longer single valued function, but a multiple valued function.

In that case, sorry is a function of two variables. And in that case if I am talking about a domain W and I am doing a double integral. So that is the sum of the function over the whole area divided by the whole area. So that is the average that you have when

you have a function of more than one variable. So you the general this idea has now got generalized.

You can of course find the average, I am not going to keep on discussing this. I am not going to do computations here. Because why to unnecessarily take time doing simple computations.

(Refer Slide Time: 04:56)

We will now discuss the notion of center of mass of a body or a collection of masses was already known to Archimedes; Archimedes that great Greek geometer and scientist. So what did Archimedes do? Archimedes had a seminal contribution to science. Not only he who found the area of circles, area of segments of parabola, but his key idea rested on something called the law of levers.

The law of levers is that okay, here is a lever. So we are talking about the law of levers. So here is a mass m_1 and here is a mass m_2 . If I just put a, if I try to put my hands anywhere or put a support anywhere there is a high chance, if I put the support here more towards m_2 this m_1 mass will create a torque around that supporting point and pull the whole thing down, pull m_2 up and pull, put the m_1 down.

So this is a kind of seesaw type of thing. So Archimedes' question is, which way where should I place a pivot, this pivot so that this lever remains in equilibrium, it does not move. Where shall I place the pivot? So let me now look at it in a much more

simpler way. So let me now put along the lever I draw the x axis. And suppose this is the origin.

From the origin this is at the point x_1 , m_2 is at the point x_2 and here the pivoting is at the point x_{bar} . What do I expect? What does the law of lever says? The law of lever says, as the distance of the pivot from m_1 multiplied by m_1 should be equal to the distance of the pivot from m_2 and multiplied by the mass m_2 . If these two quantities are equal, so what I do? What is the distance of the pivot from m_1 ?

It is $x_{bar} - x_1$. This multiplied with m_1 must equal, so this is the law of levers. So this is finally the law of levers. This is what Archimedes did. Proving it is slightly difficult. There is a whole book by David Spivak, who also has a beautiful book on calculus. He has actually tried to explain why it is not so easy to prove the law of lever of Archimedes, right?

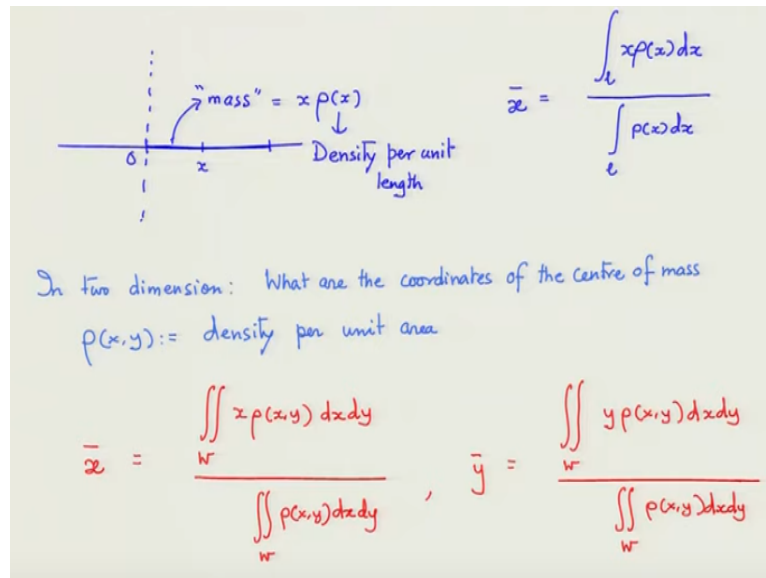

And that very simple mechanics problem can be very hard and there are logical issues. So, okay let us assume that we accept the law of levers. If I take the law of levers and because in practice that is what happens. Please understand, even the area of the circle that which Archimedes developed or the area of the segments of the parabola which was known to Archimedes was based on the idea of the law of levers.

So it says that if the lever need not move it has to remain at rest then it must have m_2 into the distance from the pivot that is x_2 . So what do I have? I have $m_1 x_{bar} - m_1 x_1$ is equal to $m_2 x_2 - m_2 x_{bar}$. So this gives me $m_1 x_{bar} + m_2 x_{bar}$ because I transferred this here and take this part $m_1 x_1$ to the other side; $m_1 x_1 + m_2 x_2$.

So x_{bar} , the point that I want to really locate because x_1 and x_2 are known points. The point that I want to locate is $m_1 x_1 + m_2 x_2$ divided by $m_1 + m_2$. So it is as if this x_{bar} is often called the center of mass; x_{bar} is often called the center of mass as if the both the masses, the sum of both the masses is located at the point x_{bar} . So this portion of this x_{bar} can be obtained by the law of lever of Archimedes.

\bar{x} is called the center of mass. So here I have made up a system of two discrete masses. What if I just look at a continuous body, a rigid body and then if I try to talk about a center of mass, what will happen, okay? If I then try to talk about a center of mass, a body which is lying along the x axis.

(Refer Slide Time: 10:30)

Suppose here is a body which lies along the x axis and I know that the density per unit length is $\rho(x)$, okay. Then if I want to, so far a distance of x, the mass would be that distance into the density, right? So here volume is given by the length basically. So in that case, the upper part that summation $\sum m_i x_i$, the m_i is now x into that $\rho(x)$, $\rho(x)$ is the density per unit length.

So if I come the distance x from the origin, so if I am here x from the origin okay and I am as you let me assume that the origin itself lies at one end of the rod. Then if I come a distance x on the origin, the mass is nothing but x into $\rho(x)$, where $\rho(x)$ is the density per unit length. So in that case, your \bar{x} is just trying to write down a continuous version of the thing that we obtained from the Archimedes' law of lever.

I then want to write a continuous version of \bar{x} equal to $m_1 x_1 + m_2 x_2$ by $m_1 + m_2$. So if I had more masses it will be summation $m_i x_i$ by summation m_i . So that idea can be now progressed with the use of integral in this continuous mass. So here I have this \bar{x} , this m_i instead of m_i the role is now played by m , $m dx$, $m x dx$, at every x what is the mass.

So $\int \rho \, dx$ integration of that whole length basically the length l if I say an integral $\int \rho \, dx$ is the total mass, summation $\sum m_i$ that is the total mass. So now if I am in two dimension, see if I am in two dimension, what are the coordinates of the center of mass? In this case the density cannot be per unit length but has to be per unit area. So the density has to be like this.

So if you take a small unit area around x, y $\rho(x, y)$ is the density per unit area. Here similarly, the coordinates would be given in the following way; \bar{x} has to deal with x part only. So could be a region W $\rho(x, y) \, dx \, dy$ integral over the total area. So density per unit area. So the area of the, so the volume or the mass of $dx \, dy$ the unit elemental areas the mass of the elemental area is actually $\rho(x, y) \, dx \, dy$.

And \bar{y} is replacing the same thing, but x is replaced by y . That is what we are expecting. Of course, you can definitely talk about I am not going to do integrations here. I am just giving you the conceptual issues here because it is unnecessary to do same kind of integration. But I will show you some type of integration which will be useful. I will do one temperature thing. So you see here, what happens.

Can I take it to the notion of, can I take this whole thing to three dimensional system. So in a three dimensional body now, I have a point $\bar{x} \, \bar{y} \, \bar{z}$ which has to be the center of mass. So in a three dimensional body, so what is now three dimensional case, three dimensional body.

(Refer Slide Time: 16:18)

Three dimensional body

Volume = $\iiint_V dx \, dy \, dz$

Mass = $\iiint_V \rho(x, y, z) \, dx \, dy \, dz$

$\bar{x} = \frac{\iiint_V x \rho(x, y, z) \, dx \, dy \, dz}{\iiint_V \rho(x, y, z) \, dx \, dy \, dz}$

$\bar{y} = \frac{\iiint_V y \rho(x, y, z) \, dx \, dy \, dz}{\iiint_V \rho(x, y, z) \, dx \, dy \, dz}$

$\bar{z} = \frac{\iiint_V z \rho(x, y, z) \, dx \, dy \, dz}{\iiint_V \rho(x, y, z) \, dx \, dy \, dz}$

$\langle f \rangle = \frac{\iiint_V f(x, y, z) \, dx \, dy \, dz}{\iiint_V dx \, dy \, dz}$

So let us take a body which is a closed bounded nice three dimensional body, body actually means a closed and bounded set like this. So we are trying to find a kind of point where all the mass would seem to be concentrated. So \bar{x} \bar{y} \bar{z} . So what is the volume of this body? So we will call this body as V to differentiate everything. So volume integral, integral, integral $V dx dy dz$.

Now if for every unit volume $\rho(x, y, z)$ at a point x, y, z if the density is $\rho(x, y, z)$. Then if you take a x, y, z point lies in a elemental volume $dx dy dz$ and if the density does not change much. If you take the density remains constant over unit volume that is what is $\rho(x, y, z)$. Then in a very small elemental volume the density would also remain as $\rho(x, y, z)$. That will remain constant, do not vary.

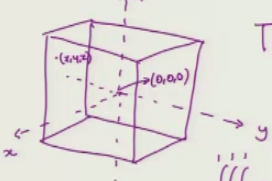

So the mass in an elemental volume is $\rho(x, y, z) dx dy dz$ so density into volume. So the total mass is to integrate over the volume, total mass of this body V of the density $\rho(x, y, z)$. So the center of mass, which is called the center of mass, the center of mass \bar{x} coordinates. The same story which goes on, do not worry is $V \times \rho(x, y, z) dx dy dz$ divided by the mass.

If I have to write for \bar{y} , so \bar{y} will be the same story but x now replaced by y . So it is a repetitive writing which I do not want to do or for completeness sake, people might just ask me that why did you not write it in detail, I would complete the writing; $\rho(x, y, z) dx dy dz$. Of course, you can talk about \bar{z} , \bar{z} is the same story where we have z instead of x or y .

Obviously, got V and then we write down over V the total mass. Now if you want to find the average, what is f average in this case? f average is integrating over $V f(x, y, z) dx dy dz$ and then dividing by the total volume. That is it. That is neatly summed up for the three dimensional body, for example. So let us go to the next page. And then here we start discussing a small problem.

(Refer Slide Time: 20:55)

Finding average temperature in a body

$$V = [-1, 1] \times [-1, 1] \times [-1, 1]$$

$$T \propto x^2 + y^2 + z^2$$

$$T(x,y,z) = c(x^2 + y^2 + z^2)$$

Average temp = Constant of proportionality

$$\langle T \rangle = \frac{\int_{-1}^1 \int_{-1}^1 \int_{-1}^1 c(x^2 + y^2 + z^2) dx dy dz}{8}$$

$$= \frac{c}{8} \int_{-1}^1 \int_{-1}^1 \int_{-1}^1 (x^2 + y^2 + z^2) dx dy dz$$

$$= \frac{3c}{8} \int_{-1}^1 \int_{-1}^1 \int_{-1}^1 x^2 dx dy dz = \frac{3c}{8} \int_{-1}^1 x^2 \left(\int_{-1}^1 \int_{-1}^1 dx dy \right) dz$$

$$= \frac{3c}{8} \int_{-1}^1 4x^2 dz = \frac{3c}{2} \left[\frac{z^3}{3} \right]_{-1}^1$$

$$= 0$$

So let the average, so given any, finding average temperature in a body. In this case my body V is the cube, so unit cube with center at 000 . So you can immediately visualize what kind of a body we are looking at. It is a kind of room and we are trying to get the temperature or the average temperature, okay? So let me draw, draw the, so it is a cube or other better things to draw cube.

It will be a cube of course, you can visualize it much better than me. Maybe I should draw a cube. This is also another way of drawing a cube. You know that 00 is at the center. So this could be the x axis, this is the y axis, this is the z axis. Now I am telling that okay at any point x, y, z in this cube the temperature T is proportional to x square plus y square plus z square.

So basically T is some c time some proportionality constant into x square plus y square plus z square, okay? Now I have to find the average temperature in the room. So how will I find the average temperature? So what I will do is exactly in the same way. T average is T is integral, integral, integral, where x, y, z are all varying between $-1, +1$, c into x square plus y square plus x square. Basically this is T .

So T I can write as a , now I can write it like a function $T(x, y, z)$. Here also you can put T as $T(x, y, z)$ it does not matter, into $dx dy dz$ or $dz dy dz$ it does not matter, whatever you want into the volume of the cube. And volume the cube is this length is $2 \times 2 \times 2$, so it is 8 . So 1 by 8 , I think c should be also be taken out, of $-1 -1$ to $+1, -1$ to $+1$ x square plus y square plus z square $dx dy dz$.

You see here I have actually three separate integrals, $x^2 dx dy dz$ plus $y^2 dx dy dz$ plus $z^2 dx dy dz$, and all of them will have the same answer. Because we can iterate accordingly. All of them would have the same answer, all of the three. So instead, we can write this as so say at the same integrals $3c$ by $8^{-1} +1^{-1} +1^{-1}$, I just do the z , z thing. So and multiply, they are all the same.

So I can do one of them and multiply them with 3. So that is exactly what I am doing. $-1 +1^{-1} -1$ no not $+1$. I should write this $1^{-1} 1^{-1} 1^{-1} z^2 dx dy dz$ okay. You immediately see what is happening, you immediately see. So basically what I can write here is $3c$ by $8^{-1} z^2$. I can actually take this whole integral, you see how interesting it is. -1 here also $-1 +1 dx dy$.

Basically I am looking at the area of a square of side 2 which will be 4 into dz . So basically it is $3c$ 8^{-1} to $+1$ $4z^2 dz$. So that will be $3c$ by $2 z^2 dz$ is z^3 by 3. And I am now writing the answer. The answer to this everything is finally z^3 cube means here one third minus two third. So basically it will be c , the answer would be c .

So the average the proportional so what see, by calculating the average we learn a very important physical fact that the average temperature is nothing but the constant of proportionality, average temperature. So what is the physical fact that we have learned? Average temperature is the constraint of proportionality.

See, so you have some information which the mathematics is giving you which by just looking at the proportional of, constant of proportionality you cannot say anything about, you may think that average temperature and constant of proportionality is different. But you see in this particular scenario, it is the same. It is amazing that here in this particular for this particular box, the average temperature is same as the constant the proportionality.

Of course if we change the box things will be different. But average temperature is same as constant of proportionality. So that is a physical fact that we derived from here. Well done. So here we end our discussion. We have been trying to maintain

time, because the next class will take a slightly much more time. We will be talking about line integrals, and which we will start next. So maybe I should take a break.

And then I will talk to you about line integrals. Okay, so this is what you get that these are the some ways you can of course, you can talk on moment of inertia. The book also talks about how to use all these to find the gravitational potential and all those things. But we are not getting into so much of details about physics at this moment because of the variety of students that are there.

I am sure economists would be unhappy if I just keep on talking about physics or biologists might be unhappy. So we will go over to line integrals, which we will start in the next class. Thank you.
