Lecture – 54
Results on Eigenvalues and Eigenvectors

So, now let us try to understand what are called properties of eigenvalues.

(Refer Slide Time: 00:24)

Properties of Eigenvalues

$\lambda_1 + \lambda_2 = \text{Tr}(A)$
 $\lambda_1 \lambda_2 = \det(A)$

$A_{2 \times 2}$

$$A = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{bmatrix}$$

$$\det(\lambda I - A) = \begin{vmatrix} \lambda - a_{11} & -a_{12} & \dots & -a_{1n} \\ -a_{21} & \lambda - a_{22} & \dots & -a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ -a_{n1} & -a_{n2} & \dots & \lambda - a_{nn} \end{vmatrix}$$

main diagonal

$$= (\lambda - a_{11}) \dots (\lambda - a_{nn}) + \dots$$

+ (n-1) more terms

A polynomial of degree n. Hence over \mathbb{C} , it will have n roots, say $\lambda_1, \lambda_2, \dots, \lambda_n$

coeff of $\lambda^n \leftarrow 1$

$$\det(\lambda I - A) = p(\lambda) = (\lambda - \lambda_1)(\lambda - \lambda_2) \dots (\lambda - \lambda_n) = \prod_{i=1}^n (\lambda - \lambda_i)$$

In the example that we had done till now look at remember those things. Where there we had shown that if λ_1 and λ_2 are eigenvalues it was for 2×2 matrices if you remember then $\lambda_1 + \lambda_2$ was nothing, but trace of A and their product was nothing, but the determinant of A alright.

Now, I would like to prove this result for the general setup that indeed it is true, fine. So, let us look at A whatever we have. So, A is sum $a_{11} \ a_{12} \ a_{1n} \ a_{21} \ a_{22} \ a_{2n} \ a_{n1} \ a_{n2} \ a_{nn}$. Let

us come to determinant of $\lambda I - A$. So, what is the determinant of $\lambda I - A$? It is nothing, but determinant of $\lambda I - A$ is $\lambda^n - a_{11}\lambda^{n-1} - a_{12}\lambda^{n-2} - \dots - a_{1n}\lambda - a_{22}\lambda^{n-2} - \dots - a_{n1}\lambda - a_{n2}\lambda - \dots - a_{nn}$. So, this is what I have.

What we know is that this is a polynomial. So, look at just look at the diagonal here the main diagonal. So, look at the main diagonal λ appears n times and therefore, it is a polynomial in λ of degree n ; that we had said earlier also. I did not do it, I just made a new statement. So, you can see here that λ see if I look at this it corresponds to looking at $\lambda^n - a_{11}\lambda^{n-1} - \dots - a_{nn}$ plus n factorial minus 1 more terms alright.

So, when we compute the determinant there are n factorial terms. Out of those n factorial terms I have 1 term which is this which corresponds to the main diagonal and then there are other terms also which are playing a role here as far as the determinant is concerned.

So, since it is $\lambda^n - a_{11}\lambda^{n-1} - \dots - a_{nn}$ this itself is a polynomial of degree n and therefore, I will have degree n polynomial, fine. So, a polynomial of degree n . Hence over complex numbers hence over \mathbb{C} it will have n roots say $\lambda_1, \lambda_2, \dots, \lambda_n$, fine.

They may be distinct they may not be distinct that I am not bothered about, but they will have n roots. Once I have n roots what you are saying is that if I look at determinant of $\lambda I - A$, this was nothing, but the characteristic polynomial fine, there was a notation for characteristic polynomial.

So, I can write this as see these are the roots I can write this as $(\lambda - \lambda_1)(\lambda - \lambda_2)\dots(\lambda - \lambda_n)$ I can write like this because those are the roots and look at the coefficient of λ to the power n coefficient of λ to the power n .

Coefficient of λ to the power n here is 1 and the same thing is true here also that coefficient of λ to the power n is 1 and hence everything makes sense. There is no

problem here. We generally write it in terms of product lambda minus lambda i i is equal to 1 to n, in my notes or everywhere else this is the way we write.

So, the idea is to understand the two things the left hand side is this expression which is quite long the right hand side is just a polynomial which has been factored into linear factor which has been factored. So, there are two terms and from there I want to build up my ideas, alright.

(Refer Slide Time: 04:40)

A polynomial of degree n. Hence roots, say $\lambda_1, \lambda_2, \dots, \lambda_n$ etc.

need to remove and i column

$\det(\lambda I - A) = p(\lambda) = (\lambda - \lambda_1)(\lambda - \lambda_2) \dots (\lambda - \lambda_n) = \prod_{i=1}^n (\lambda - \lambda_i)$

coeff of λ^{n-1}

(1) Trace(A) = $a_{11} + a_{22} + \dots + a_{nn}$

appears in coefficient of λ^{n-1} of $(\lambda - a_{11})(\lambda - a_{22}) \dots (\lambda - a_{nn})$

coeff of λ^{n-1} in $\det(\lambda I - A) = -(a_{11} + a_{22} + \dots + a_{nn})$ etc

Any Term which is NOT the main diagonal contributes at most coeff of λ^{n-2}

$(\lambda - a_{11})(\lambda - a_{22})(\lambda - a_{33})$ etc

$= \lambda^3 - \lambda^2(a_{11} + a_{22} + a_{33}) + \lambda(a_{11}a_{22} + a_{11}a_{33} + a_{22}a_{33}) - a_{11}a_{22}a_{33}$

$(\lambda - \alpha)(\lambda - \beta)(\lambda - \gamma) \rightarrow \lambda^3 - (\alpha + \beta + \gamma)\lambda^2 + (\alpha\beta + \alpha\gamma + \beta\gamma)\lambda - \alpha\beta\gamma$

So, let us try to do that part let us try to understand. So, first thing is what about trace of A? How do I get trace of A? So, what we know is that trace of A is nothing, but a 11 plus a 22 plus a nn alright. Now, where does that term appear? So, if I look at this thing appears at this place.

Look at the main diagonal here look at the main diagonal, fine, look at coefficient of lambda to the power $n - 1$. So, this appears in coefficient of lambda to the power $n - 1$ of $\lambda^{n-1} a_{11} \lambda^{n-2} a_{22}$ so on till $\lambda^{n-1} a_{nn}$ alright, fine. And, there is no other term of lambda to the power $n - 1$.

Why? Because if I do not want a term of lambda to the power n so, if I look at this part the main diagonal main diagonal gives me lambda to the power n lambda to the power $n - 1$ lambda to the power $n - 2$ and so on, fine.

If I do not want to look at the main diagonal, if I want to look at any other thing alright so, as soon as I look at any other term here for example, if I want to look at any term here, then this tells me that I will have to remove this row and I will have to remove this column this is what the determinant was.

Determinant means if I am looking at there is a term a_{ij} $i \neq j$; it means that need to remove the i -th row and j -th column. Now, if I were to remove i -th row and j -th column it means that j -th column means this will give me $\lambda^{n-1} a_{jj}$ will get cancelled out and from here I will get $\lambda^{n-1} a_{ii}$ cancelled out alright. So, one of them will always get cancelled out. This what you have to understand.

So, when I want to compute the determinant; determinant has $n!$ factorial terms, out of that there are what are called the main diagonal and the rest are $n! - 1$ terms. If I look at this $n! - 1$ terms lambda to the power $n - 1$ does not appear.

So, lambda to the power $n - 1$ does not appear. Why? basically because I will get some a_{ij} and that a_{ij} and there I know that $i \neq j$ so there will be at least one term a_{ij} which is $i \neq j$ and that will get rid of $\lambda^{n-1} a_{ii}$ as well as $\lambda^{n-1} a_{jj}$.

And, therefore, there will be only lambda to the power $n - 2$ terms at most lambda to the power $n - 2$ terms. So, any other non-diagonal elements. So, any other term here. So, this

term so, any term which is not the main diagonal contributes at most λ to the power n minus 2 coefficient of λ to the power n minus 2 it would not compute give me λ to the power n or λ to the power n minus 1 is that.

So, let us go back now. So, I am looking at trace; trace of A is this. So, this is same thing as looking at appears in the coefficient of λ to the power n minus 1 which is this and how does it come com? So, if we look at λ to the power n minus 1, the term here is coefficient of λ to the power n minus 1 in determinant of $\lambda I - A$ I wrote $\lambda I - A$ is nothing, but minus of a_{11} plus a_{22} plus a_{nn} .

Look at here, fine? Why it is happening? So, let me write that nicely maybe there will be some clarity. So, I want to look at $\lambda - a_{11}$ $\lambda - a_{22}$ and $\lambda - a_{33}$ then I would like you to see that this is nothing, but $\lambda^3 - \lambda^2(a_{11} + a_{22} + a_{33}) + \lambda(a_{11}a_{22} + a_{11}a_{33} + a_{22}a_{33}) - a_{11}a_{22}a_{33}$, alright. This is what we have.

So, basically what we are saying is that any polynomial if these are the roots α β γ are the roots. So, if α β γ are the roots if. So, I should be written $(X - \alpha)(X - \beta)(X - \gamma)$ then this corresponds to $X^3 - (\alpha + \beta + \gamma)X^2 + (\alpha\beta + \alpha\gamma + \beta\gamma)X - \alpha\beta\gamma$. This is what we are writing here nothing else, fine.

So, what we see is that I have got this part coefficient of λ to the power n is this, but what we are saying here is understand carefully there should not be a confusion that I am writing determinant also as like this, fine. So, I think I should go to the next page for clarity.

(Refer Slide Time: 10:36)

$$\det(\lambda I - A) = p(\lambda) = \prod_{i=1}^n (\lambda - \lambda_i) = (\lambda - \lambda_1)(\lambda - \lambda_2) \dots (\lambda - \lambda_n)$$

$(\lambda - a_{11})(\lambda - a_{22}) \dots (\lambda - a_{nn})$
 + (n-1) other terms

Look at coefficient of λ^{n-1} on both sides

LHS: λ^{n-1} appears only in $(\lambda - a_{11})(\lambda - a_{22}) \dots (\lambda - a_{nn})$
 coeff of λ^{n-1} as $-(a_{11} + a_{22} + \dots + a_{nn})$

RHS: coeff of λ^{n-1} as $-(\lambda_1 + \lambda_2 + \dots + \lambda_n) = -\text{Tr}(A)$

$\text{Tr}(A) = \lambda_1 + \lambda_2 + \dots + \lambda_n$

$\det(A)$ substitute $\lambda = 0$ to get $p(0) = \det(-A) = (-1)^n \det A$
 $(0 - \lambda_1)(0 - \lambda_2) \dots (0 - \lambda_n) = (-1)^n \lambda_1 \lambda_2 \dots \lambda_n$

So, what we have taken is determinant of lambda I minus A. One way this is nothing, but the characteristic polynomial we wrote it as product i going from 1 to n lambda minus lambda i which is same as lambda minus lambda 1, lambda minus lambda 2 lambda minus lambda n. This was one term of this was lambda minus a 11 a 22 lambda minus a nn plus n factorial minus 1 other terms. This is what we had alright.

So, in this I am looking at so, look at coefficient of lambda to the power n minus 1 on both the sides on both sides. So, on the left hand side if I look at left hand side as I said lambda to the power n minus 1. So, lambda to the power n minus 1 appears only in lambda minus a 11 lambda minus a 22 lambda minus a nn and this gives me coefficient of lambda to the power n minus 1 as minus of a 11 plus a 22 plus a nn, alright.

If I look at the right hand side; right hand side is basically this itself and therefore, this will give me coefficient of lambda to the power n minus 1 as minus of lambda 1 plus lambda 2 plus lambda n, fine and therefore, I know that this is nothing, but A. So, this will be same as this, this minus sign and this minus sign they cancel out alright negative sign cancels fine.

So, therefore, what I get is that trace of A is nothing, but some of the eigenvalues fine. What about the determinant let us look at determinant of A. So, if I want to get the determinant of A, I need to substitute lambda equal to 0 here, alright.

So, if I substitute lambda equal to 0, what I get is. So, substitute lambda is equal to 0 to get p 0 is equal to determinant of minus A which is same as minus 1 to the power n into determinant of A. Why minus 1 to the power n? Because this matrix is of size n cross n alright.

So, I multiplying by a scalar minus 1. So, that gets multiplied fine, what about the right hand side? Look at the right hand side; right hand side right hand side is nothing, but 0 minus lambda 1 0 minus lambda 2 0 minus lambda n which is same as minus 1 to the power n lambda 1 lambda 2 lambda n.

(Refer Slide Time: 13:47)

$(\lambda - a_1)(\lambda - a_2) \dots (\lambda - a_n)$
 $+ (n-1) \text{ other terms}$

Look at coefficient of λ^{n-1} on both sides

LHS. λ^{n-1} appears only in $(\lambda - a_1)(\lambda - a_2) \dots (\lambda - a_n)$
 coeff of λ^{n-1} as $-(a_{11} + a_{22} + \dots + a_{nn})$

RHS. coeff of λ^{n-1} as $-(\lambda_1 + \lambda_2 + \dots + \lambda_n)$

$\text{Tr}(A) = \lambda_1 + \lambda_2 + \dots + \lambda_n$

$\det(A) = \det(-A) = (-1)^n \det A$
 $(0 - \lambda_1)(0 - \lambda_2) \dots (0 - \lambda_n) = (-1)^n \lambda_1 \lambda_2 \dots \lambda_n$

$\Rightarrow \boxed{\det A = \lambda_1 \lambda_2 \dots \lambda_n}$

And, therefore, I get that minus 1 to the power n minus 1 to the power n cancels out I get determinant of A is nothing, but lambda 1 lambda 2 lambda n, fine. So, we have shown that trace of A is same as sum of the eigenvalues and determinant is nothing, but the product of eigenvalues it is very important idea it helps us at lot of places.

There are other things also you can go for 2 by 2, 3 by 3 and so on, but that is not in our syllabus. Our syllabus is only about trace and determinant. So, you need to keep track of that, fine.

(Refer Slide Time: 14:30)

The image shows handwritten notes on a whiteboard. At the top, it says "Spectrum of a Matrix" with an arrow pointing down to "eigenvalues of A". To the right, it says "let λ be an eigenvalue of A". Below this, "Algebraic Multiplicity $A(\lambda)$ " is defined as "the multiplicity of λ as a ROOT of the characteristic poly $\det(xI-A)$ ". To the right of this definition, it says "poly of degree n". Below that, "Geometric Multiplicity $A(\lambda)$ " is defined as $\frac{\dim(\text{Null}(xI-A))}{\dim(\text{Null}(A-\lambda I))}$. An example is given: "Example: ① $A = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix}$ ". To the right of the matrix, the characteristic polynomial is calculated: $\det(xI-A) = \begin{vmatrix} x-1 & -1 & 0 \\ 0 & x-1 & -1 \\ 0 & 0 & x-1 \end{vmatrix} = (x-1)^3$. An arrow points from the result $(x-1)^3$ to the algebraic multiplicity calculation: $\rightarrow \text{alg. mult}_A(1) = 3$. Below this, it says "geo. mult $A(1) = \dots$ ". The whiteboard interface includes a menu bar (File, Edit, View, Insert, Actions, Tools, Help), a toolbar with drawing tools, and a color palette. The page number "15" is visible at the bottom.

Now, let us look at what are called algebraic multiplicity and things like that. So, let me go into the next idea what. So, let us concentrate on a spectrum of matrix. So, spectrum means eigenvalues so, of A, fine. Then there is a notion of what are called now algebraic multiplicity and there is a notion of what is called geometric multiplicity.

So, algebraic geometric multiplicity of what? Eigenvalues of this, alright. So, let lambda be an eigenvalue of A. Recall, we are doing everything over complex numbers. So, let lambda be an eigenvalue of A.

This is the assumption then there is a notion algebraic multiplicity of lambda as an eigenvalue of A. So, this is the multiplicity of lambda as a root of the characteristic polynomial determinant of XI minus A. So, this is a polynomial of degree n polynomial of degree n, fine.

Now what is a geometric multiplicity? This corresponds to the dimension of the null space of $\lambda I - A$ that I am looking at. So, it is as you can write $\lambda I - A$ or $A - \lambda I$, whichever you are comfortable with, you are supposed to look at this.

So, geometric multiplicity is the dimension, fine. So, let us take an example to understand it, so that I can proceed further. So, so example. So, let me take one example. I define A as $\begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$. I look at this alright, fine. So, I want to compute the determinant of $XI - A$ which is the same as the determinant of $X - 1$ $X - 1$ $X - 1$. So, this is an upper triangular matrix. So, the determinant of this is $X - 1$ to the power 3.

So, this implies algebraic multiplicity of 1 as an eigenvalue of A is 3, fine, because 1 is repeated thrice, fine. What about the geometric multiplicity? For the geometric multiplicity I need to compute this null space. So, let us compute the dimension of the null space. So, we want to compute. So, we want to look at the geometric multiplicity of 1 here alright. So, this is equal to what? So, let us do that out.

(Refer Slide Time: 17:58)

Handwritten notes on a whiteboard:

- Top left: \Rightarrow alg. mult_A(1) = 3, geo. mult_A(1) = 1
- Top right: $\lambda = (X-1)$, Null(I-A) $\leftrightarrow \begin{bmatrix} 0 & -1 & 0 \\ 0 & 0 & -1 \\ 0 & 0 & 0 \end{bmatrix}$, Rank(I-A) = 2, $\Rightarrow \dim(\text{Null}(I-A)) = 3 - \text{Rank}(I-A) = 1$
- Middle left: Matrix A with Jordan blocks: $A = \begin{bmatrix} 3 & 1 & 0 & 0 & 0 \\ 0 & 3 & 1 & 0 & 0 \\ 0 & 0 & 3 & 0 & 0 \\ 0 & 0 & 0 & 2 & 1 \\ 0 & 0 & 0 & 0 & 2 \end{bmatrix}$. Note: Rank(3-A)
- Middle right: $\sigma(A) = \{3, 3, 3, 3, 3, 2, 2, 2\}$, alg_A(3) = 5, alg_A(2) = 3, A-2I
- Bottom left: geo mult_A(3) = 8 - 6 = 2, geo mult_A(2) = 8 - 7 = 1
- Bottom right: Jordan blocks for $\lambda=3$ and $\lambda=2$.

So, I need to look at null space of I lambda is 1 here. So, I am supposed to look at I minus A null space of this. So, this corresponds to looking at just have a look at it 1 minus A. So, this corresponds to the matrix replace X by 1 here. So, if I do that 1 minus 1 is 0 minus 1 0 0 0 minus 1 0 0 0 alright.

So, this is the matrix that I am looking at. Now, the rank of this matrix is 2 rank of I minus A is 2. This implies dimension of null space of A will be equal to 3 minus the rank of I minus A by the rank nullity theorem which is 1 alright. So, the geometric multiplicity is 1 is that try that out yourself.

Another example so, another form of this was already given to you earlier. I will write it now with 3 here 1 here 0 0 3 1 0 0 3 I look at this, fine and again I look at say 3 1 0 3 2 1 0 0 2 1 0

0 0 or 0 0 2 suppose I look at this matrix huge matrix for us fine. So, all these entries are 0 for us fine. So, I would like you to see that this is an upper triangular matrix.

So, the eigenvalues a spectrum of A here consists of 3 3 3 3 3 5 times 3 plus 3 3 plus 2 and 2 appears 3 times. So, this is an spectrum of A, fine. Algebraic multiplicity of 3 as an eigenvalue of A is 3 plus 2 is 5 algebraic multiplicity of 2 as an eigenvalue of A is 3.

What about the geometric multiplicity? Check that the geometric multiplicity of 5 of 3 as an eigenvalue of as an eigenvector here will be equal to. So, this will give me a look at the previous example. If we use the previous example the rank of this if I look at this whole part A, I want to look at the rank of that part. So, I want to compute rank of $3I - A$ if I look at that part what will happen is, this will become 0, this will become 0, this will become 0.

So, the top one gives me only rank 2 this is 0, this is 0. So, it gives you one more rank. So, rank is 3 1 2 3 rank is 3. What about here? Here I will get 3 minus 1 so it will give 3 minus 2 is 1, again 3 minus 2 is 1, again 1 here. So, this will give me a full rank 3. So, rank is 3 plus 1 is 4, 5 and 6. So, rank of this is 6. This matrix is of size what is the size of this matrix 3 plus 3 6 plus 2, 8. So, 8 minus 6 which is 2 alright.

So, the geometric multiplicity of this is 2. If you look at geometric multiplicity of 2 here will be equal to 8 minus, now I need to remove. So, I need to look at now 2 here 2. So, 2 minus that is 2 minus 2 minus 3 will be minus 1 fine, while or let me look at 3 minus. So, let me look at $A - 2I$; if I look at $A - 2I$. I will look at 3 minus 2 is 1, 1 here and 0 1 1 0 0 1 this is the first part. Second block will give me 1 1 0 1 and the last part will give me 0 1 0 0 0 1 0 0 0 alright, fine.

So, therefore, if I see the rank of this matrix is 3 plus 2 5 plus 1 6 plus 1 7. So, 8 minus 7 which is 1, fine. So, I have certain issues that you can see here that this matrix is not a diagonal matrix and what we see here is that look at the previous examples also our matrix whenever it was not a diagonal matrix, fine so, this number is not same as this number.

Algebraic multiplicity is 5, geometric multiplicity is 2; algebraic multiplicity is 3, geometric multiplicity is 1.

(Refer Slide Time: 22:43)

Examples: ① $A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$ Any collection of 3 L.I. vectors form a basis of $\text{Null}(A - I_3)$.
 $1, 1, 1 \in \sigma(A)$
 Repeated 3 times
 we have 3 L.I. eigenvectors
 $(1, 0, 0), (0, 1, 0), (0, 0, 1)$

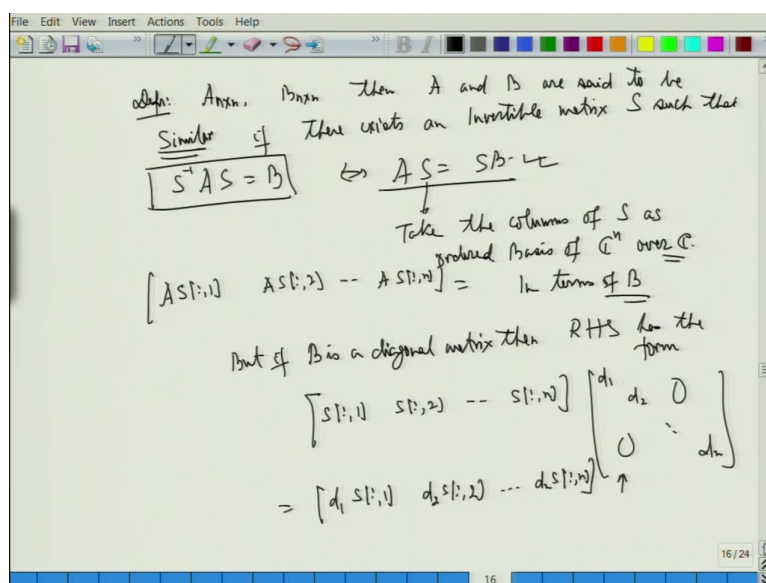

② $A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$ $\det(A - \lambda B) = \begin{vmatrix} -\lambda & 1 \\ 0 & -\lambda \end{vmatrix} = \lambda^2$
 $\Rightarrow 0, 0 \in \sigma(A)$
 $\text{Null}(A - 0B) = \text{Null}(A) = \{x \in \mathbb{R}^2 \mid Ax = 0\} = \{ \begin{bmatrix} x \\ 0 \end{bmatrix} \in \mathbb{R}^2 \mid \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} x \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \}$
 $= \{ \begin{bmatrix} x \\ 0 \end{bmatrix} \mid x \in \mathbb{R} \}$
 has dimension 1. Even though 0 is an eigenvalue of multiplicity 2, it is a root of characteristic equation with multiplicity 2, but it is a root twice.

There is an eigenvalue example where there are NOT sufficient eigenvectors.

Look at previous examples also wherever we have looked at, fine. Look at this here it is a diagonal matrix. So, algebraic multiplicity is same as the geometric multiplicity because there 1 was repeated 3 and I had three linearly independent eigenvectors. Look at here, fine. Here and I have only one eigenvector fine and this is not an example of a diagonal matrix, fine.

So, we will come across all these ideas in the next class, fine. So, I will like you to understand them which are very important. Now, so, let me just do something now at the last part of this problem; let me do this what are called similar matrix definition.

(Refer Slide Time: 23:21)

Definition. So, A is n cross n , B is n cross n then A and B said to be similar if there exists an invertible matrix S such that SAS inverse is B alright or recall that I can write this as which is same thing as writing or I should have written S inverse here I think and S here AS is equal to SB is the same thing because you are just changing them.

We are saying that A of S is same as S of B think of S . So, take the columns of S as ordered basis of \mathbb{C}^n over \mathbb{C} , fine. Then what we are saying is that I have got a here I am applying. So, S is there, so, I am applying A to the first column, A to the second column and so on A to the n -th column. I am looking at this and then I am saying that this is same as S times B .

So, now I am looking at the other way around the column wise alright. So, you can write again like this itself in terms of B ; in terms of B fine, this is what it is, but if B is a diagonal matrix, then RHS has a nice form RSS has the form alright. So, S I am looking at the first

column, the second column, the nth column whether I am multiplying by diagonal matrix say d_1, d_2, \dots, d_n here 0 here then d_1 .

So, this first column is getting multiplied to the first one, second to the second and so on. So, this corresponds to d_1 times S of this due to time S of this and d_n time S of this fine. So, look at this in general if I am looking at just any B , I do not get anything, alright. It is just an expression AS is equal to SB and that appeared at the time of looking at matrix of the linear transform composition of matrices and we said that we need to understand that to talk of similarity operation, alright.

(Refer Slide Time: 26:34)

$[AS^{(1,1)} \quad AS^{(1,2)} \quad \dots \quad AS^{(1,n)}] =$ in terms of $B \rightarrow$ produced basis of \mathbb{C}^n over \mathbb{C} .
 But if B is a diagonal matrix then RHS has the form
 $[S^{(1,1)} \quad S^{(1,2)} \quad \dots \quad S^{(1,n)}] \begin{bmatrix} d_1 & & & \\ & d_2 & & \\ & & \ddots & \\ 0 & & & d_n \end{bmatrix}$
 $= [d_1 S^{(1,1)} \quad d_2 S^{(1,2)} \quad \dots \quad d_n S^{(1,n)}]$
 $[AS^{(1,1)} = d_1 S^{(1,1)}]$ eigen-pair $(d_1, S^{(1,1)})$ So, we have got n L.I. eigenvalues
 In general $S^{-1} A S = B$
 $\text{Tr}(A) = \text{Tr}(S^{-1} A S) = \text{Tr}((AS) S^{-1}) = \text{Tr}(A S S^{-1}) = \text{Tr}(A I) = \text{Tr}(A)$
 $[\text{Tr}(AB) = \text{Tr}(BA)]$

Here what we are saying here is that in this case if B is a diagonal matrix if B is diagonal then what we are seeing is that look at this part. This part, it says that the first column is nothing, but an eigenvector. So, this gives me eigen-pair d_1 and this recall that any invertible matrix

cannot have a zero vector inside it. So, S is a nonzero vector. Not only that since S is invertible all these columns are linearly independent.

So, we have got n linearly independent eigenvectors. So, we have got n linearly independent eigen vectors alright. So, I would like you to keep track of that. Further in general, what we are saying here is that in general we are saying that $S^{-1}AS$ is B . So, let us look at the trace. What is trace of $S^{-1}AS$ which is same as trace of B alright. So, this is same as trace of I can interchange. So, what we know is that trace of AB is same as trace of BA , fine.

That we had seen earlier. So, this is same as trace of AS into S^{-1} which is same as trace of ASS^{-1} , alright, fine which is same as trace of A . So, when I do similarity transformation the trace does not change, fine.

(Refer Slide Time: 28:10)

$$A s^{(i)} = d_i s^{(i)}$$
 eigenpair $(d_i, s^{(i)})$

$$= [d_1 s^{(1)} \quad d_2 s^{(2)} \quad \dots \quad d_n s^{(n)}]^T$$

So, we have got n L.I. eigenvectors

In general, $S^{-1}AS = B$

$$\text{Tr}(B) = \text{Tr}(S^{-1}AS) = \text{Tr}(AS S^{-1}) = \text{Tr}(A S S^{-1}) = \text{Tr}(A)$$

Trace does NOT change under similarity transformation.

$$\det(B) = \det(S^{-1}AS) = \det(S^{-1}) \cdot \det(A) \cdot \det(S)$$

$$= \det(A) \quad (\det(S^{-1}) \det(S) = 1)$$

Under similarity eigenvalues do NOT change

$$\det(B - \lambda I) = \det(S^{-1}AS - \lambda I) = \det(S^{-1}(A - \lambda I)S)$$

$$= \det(A - \lambda I)$$

$\text{Tr}(AB) = \text{Tr}(BA)$
 $\det(AB) = \det A \det B$

So, trace does not change under similarity transformation. What about the determinant? We have computed the determinant also. So, what is determinant of B? Determinant of B is same as determinant of $S^{-1}AS$. I know that determinant of AB same as determinant of A into determinant of B. Determinant of AB is same as determinant of A into determinant of B.

So, let us do that. So, determinant of S^{-1} into determinant of A into determinant of S which is same as determinant of A, fine because determinant of $S^{-1}S$ is 1 alright fine. So, you can see that under similarity transformation the trace and determinant does not change can we say about eigenvalues also that the under eigenvalues things will be the same, alright?

So, I would like you to check that under determinant under the similarity. So, under similarity eigenvalues do not change. Why does not change? Because we compute determinant of why because to compute we need to compute determinant of $B - \lambda I$ which is same as determinant of $B - \lambda I$ is $S^{-1}(A - \lambda I)S$ which is same as determinant of $S^{-1}(A - \lambda I)S$ into S.

Just multiply X^{-1} as $\lambda I - X^{-1}$ again. So, you will get back this which by the same argument as above it gives me determinant of $A - \lambda I$ alright. So, therefore, the eigenvalues will remain the same, eigenvectors will change.

We will go back to this again in the next class. That is all for now.
