Lecture – 57
Diagonalizability Continued...

So, we are defined diagonalizability in the last class, we will give examples to show that some matrices are not diagonalizable. We also had this theorem, they are in some sense we did not write it that A is diagonalizable if and only if A has n linearly independent eigenvectors.

(Refer Slide Time: 00:31)

I did not state it so; let me write this as a statement theorem. A n cross n , then A is diagonalizable if and only if A has n linearly independent eigenvectors. So, this we had proven using writing the matrix P as eigenvectors $u_1 u_2 u_n$ and so on. alright.

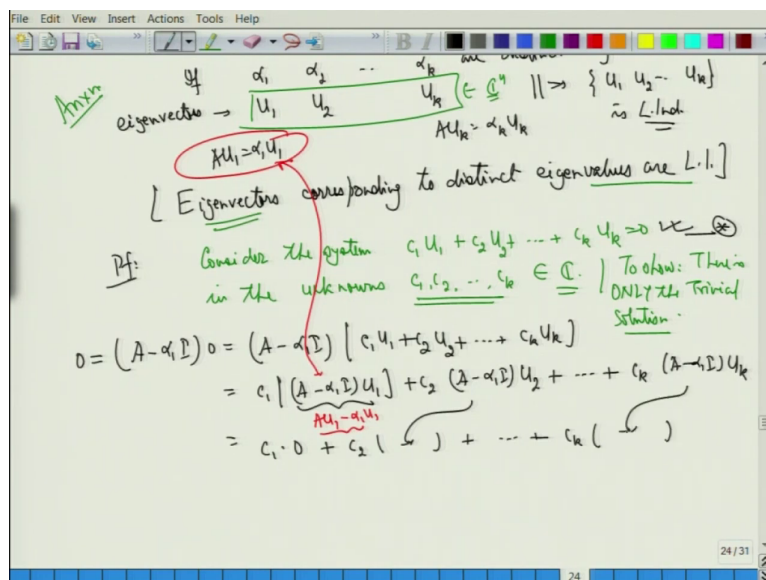

So, I will just stop that part that part I hope you have understood think about it again now. So, the next thing that we would like to do is that, when can I find linearly independent eigenvectors. So, the question what are the conditions, the conditions under which we can hope to get n linearly independent eigenvectors this is what we need alright.

So, that come we will get to that after a bit after some time. What we want to say is that we have seen till now looked at examples, where the diagonalizability has failed, because of the eigenvalue being the same in some sense fine. So, would what would like to say is that if I pick up eigenvalues which are distinct look at the corresponding eigenvectors can I say that they are linearly independent. So, the next thing that would like to say that if so, if $\alpha_1, \alpha_2, \dots, \alpha_k$ are distinct eigenvalues fine.

And you have corresponding eigenvectors u_1, u_2, \dots, u_k can I say so, these are eigenvectors fine. So, what we know is that $\alpha_1 u_1$ is equal to $A u_1$; similarly $A u_k$ is equal to $\alpha_k u_k$. So, these are eigenvectors α_i are distinct can I say that this will imply that this set u_1, u_2, \dots, u_k is linearly independent alright.

So, what we are saying is that the eigenvectors corresponding to distinct eigenvalues are linearly independent. So, we are saying eigenvectors corresponding to distinct eigenvalues are linearly independent that is what we are claiming here like. So, let us try to prove it.

(Refer Slide Time: 03:38)

So, proof fine. So, if I want to prove that this is linearly independent, I am supposed to form a system of equation let us form a system of equation. So, consider the system $c_1 u_1 + c_2 u_2 + \dots + c_k u_k = 0$ in the unknowns $c_1, c_2, \dots, c_k \in \mathbb{C}$. To show: This is ONLY the Trivial Solution. Because u_i are complex vectors alright and I am assuming that A is $n \times n$ and these are so, u_i are in \mathbb{C}^n fine so, that it makes sense.

So, I am solving the systems $c_1 u_1 + c_2 u_2 + \dots + c_k u_k = 0$ where the c_i 's are unknowns. I want to find them or since I want to prove that these are linearly independent the eigenvectors are linearly independent alright, I have to show that the only solution here is the trivial solution. To show there is only the trivial solution alright. So, what we can do is that? We can multiply this matrix this vector equation by certain matrices alright. So, let us try to multiply this by something alright.

So, I want to multiply this by say $A - \alpha I$, I want to multiply this a star by this. If I do that what do I get on the left hand side, I will get this time 0 is 0 fine. The other side I will get it as $A - \alpha I$ times $c_1 u_1 + c_2 u_2 + \dots + c_k u_k$. Now, what it gives me is just put inside c_1 times $A - \alpha I$ u_1 plus c_2 times $A - \alpha I$ u_2 plus c_k $A - \alpha I$ u_k fine this is what I get.

Now, this is equal to now what is u_1 , u_1 is an eigenvector corresponding to α or we already wrote here that $A u_1$ is equal to αu_1 . So, if I use this idea here what do I get? I get $A u_1$ if you rewrite it is $A u_1 - \alpha u_1$. So, therefore, this part tells me that this is a 0 vectors. So, what I get is here? c_1 times 0 plus c_2 times something that I am not bothered about for the time being that will write afterwards plus c_k times something here is that ok.

(Refer Slide Time: 06:47)

The image shows a handwritten mathematical proof on a digital whiteboard. At the top, it states "Eigenvectors $\rightarrow u_1, \dots, u_k$ " and "no L.I. (Linearly Independent)". Below this, it says "Eigenvectors corresponding to distinct eigenvalues are L.I.". The proof starts with "Pf: Consider the system $c_1 u_1 + c_2 u_2 + \dots + c_k u_k = 0$ in the unknowns $c_1, c_2, \dots, c_k \in \mathbb{C}$ ". It notes "To show: This is ONLY the Trivial Solution". The main derivation is:

$$0 = (A - \alpha I) 0 = (A - \alpha I) [c_1 u_1 + c_2 u_2 + \dots + c_k u_k]$$

$$= c_1 (A - \alpha I) u_1 + c_2 (A - \alpha I) u_2 + \dots + c_k (A - \alpha I) u_k$$

$$= c_1 \cdot 0 + c_2 (\quad) + \dots + c_k (\quad)$$

$$= c_2 (\quad) + c_3 (\quad) + c_k (\quad)$$
 The whiteboard also has a red circle around $A u_1 = \alpha u_1$ and a red arrow pointing from it to the $(A - \alpha I) u_1$ term in the derivation. The bottom right corner of the whiteboard shows "24 / 31".

So, by multiplying by this here alright so, by multiplying by this $A - \alpha_1 I$, I have been able to get rid of c_1 is that ok. So, c_1 has lost. So, what I got now is that? Earlier I had equation which was in c_1, c_2, c_k . Now, I have equation only in c_2 times something plus c_3 times something plus c_k times something. So, the number of variables or unknowns has reduced fine.

This is more important you are trying to again go back to your Gauss elimination method, where at each a step we have tried to reduce the number of unknowns. So, we removed c_1 . Now I want to remove c_2 fine.

(Refer Slide Time: 07:35)

The image shows a digital whiteboard with handwritten mathematical work. At the top, there is a toolbar with various drawing and editing tools. The main content consists of several lines of equations and explanatory text:

- The first line shows an equation: $= c_1 (A - \alpha_1 I) u_1 + c_2 (A - \alpha_1 I) u_2 + \dots + c_k (A - \alpha_1 I) u_k$. A red arrow points from $(A - \alpha_1 I) u_1$ to the next line.
- The second line shows: $= c_1 \cdot 0 + c_2 (\dots) + \dots + c_k (\dots)$. A red arrow points from the c_2 term to the next line.
- The third line shows: $= c_2 [\dots] + c_3 [\dots] + c_k [\dots]$. A red arrow points from the c_2 term to the next line.
- Below the equations, there is a boxed expression: $(A - \alpha_2 I) u_2 = 0$. To the left of this box, there is a note: "Identify to remove c_2 ". To the right, there is a note: "Cannot multiply to \otimes as c_2 will NOT appear, but $c_1, c_3, c_4, \dots, c_k$ will appear".
- Below the boxed expression, there are two equations:
 - $0 = c_2 (A - \alpha_1 I) u_2 + \dots + c_k (A - \alpha_1 I) u_k$
 - $0 = c_2 (A - \alpha_1 I) (A - \alpha_2 I) u_2 + \dots + c_k (A - \alpha_1 I) (A - \alpha_2 I) u_k$

The whiteboard also shows a page number "24/31" in the bottom right corner.

If I want to remove c_2 . What we need to do? I need to so, if I want to remove want to remove c_2 I need to multiply $A - \alpha_2 I$ two the first equation or to this equation alright, because what I know is that you have multiply this.

Then, $A - \alpha_2 I$ of u_2 will give me 0 fine. So, I need to multiply by this I need to multiply by this, but I cannot multiply to the first one the star cannot multiply cannot multiply to a star as c_2 will not appear not appear, but c_1, c_3, c_4 till c_k will appear alright so, will appear. So, what happens is that? I can kill c_2 , but I cannot kill c_1 alright. So, that is the problem.

So, what I would like to understand is can I do this itself multiply this to the equation that I have got here which is say double star for me alright. So, let us write the double star again. So, double star is nothing, but 0 is equal to c_2 times $A - \alpha_1 I$ times u_2 plus so on plus c_k times $A - \alpha_1 I$ u_k this is what I had fine. Let us multiply $A - \alpha_2 I$ this. If I do this alright, if I do this and also you observe we are there this is very very important observation that this matrix times this matrix is same as $A - \alpha_2 I$ times $A - \alpha_1 I$.

That is these two matrices commute. So, this and $A - \alpha_1 I$ they commute. Why do they commute? Because, I am just multiplying by a itself and by identity, identity commutes with everything the scalar matrix $\alpha_1 I$ or $\alpha_2 I$ they are a scalar matrices, they commute alright. So, I would like you to check that they commute here. And therefore, I can just write this as 0 times c_2 of $A - \alpha_1 I$ times $A - \alpha_2 I$ u_2 and so on, I can go on plus c_k times $A - \alpha_1 I$ into $A - \alpha_2 I$ u_k .

(Refer Slide Time: 10:14)

$$0 = c_3 (A - \alpha_1 I)(A - \alpha_2 I) u_3 + \dots + c_k (A - \alpha_1 I)(A - \alpha_2 I) u_k$$

Defn $T_1 = \prod_{i=1}^n (A - \alpha_i I) / (A - \alpha_1 I) \rightarrow (A - \alpha_2 I) \dots (A - \alpha_k I)$ *Commutative*

$T_2 = \prod_{i=1}^n (A - \alpha_i I) / (A - \alpha_2 I) \rightarrow (A - \alpha_1 I)(A - \alpha_3 I) \dots (A - \alpha_k I)$ *NOT commutative*

$$T_1 (c_1 u_1 + c_2 u_2 + \dots + c_k u_k) = T_1 \cdot 0 = 0$$

$$c_1 \underline{T_1 u_1} + c_2 \underline{T_1 u_2} + \dots + c_k \underline{T_1 u_k} = 0$$

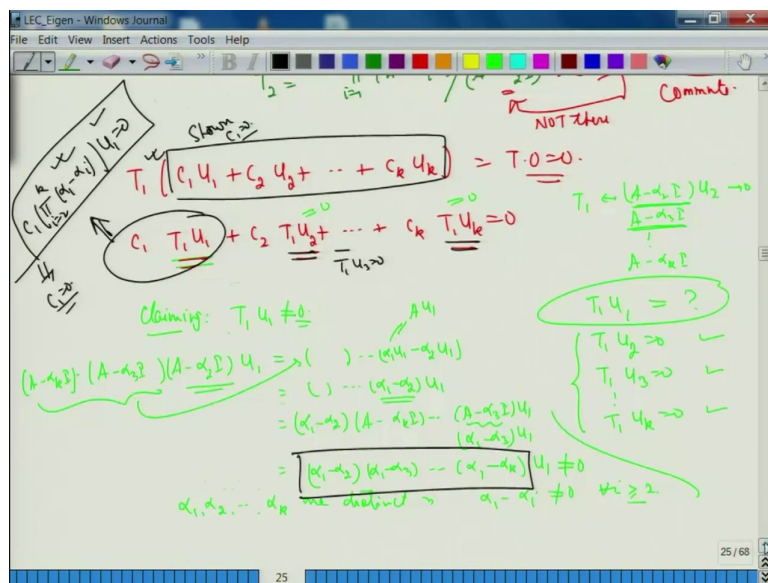

If I do this what will happen is? This has become 0 now I will be left out with 0 is equal to c 3 times A minus alpha 1 I A minus alpha 2 I fine times u 3 plus so on plus c k times A minus alpha 1 I into A minus alpha 2 I times u k fine. So, this is what I will be left out with this is what you have to understand fine. So, in general what I am doing let us rewrite this in a nice form so, that you understand it fine. So, I would like to write these matrices.

So, I want to write some matrix. So, I define T 1 is equal to product A minus alpha i of identity I is equal to 1 to n divided by A minus alpha 1 of I. So, this one comes with this one for me is that ok. So, I am defining my T 1 like this. Similarly I can define T 2 as product I is equal to 1 to n a minus alpha i of I and then divide by A minus alpha 2 of I fine. So, if I look at this what I am trying to say is that this corresponds to looking at A minus alpha 2 I so on till A minus alpha k of I.

This corresponds to looking at $A - \alpha_1 I$, then $A - \alpha_2 I$, then $A - \alpha_3 I$, then $A - \alpha_k I$. And what I know is that these matrices commute, they commute here fine. Because, I am just multiplying a with identity so, they commute. So, if I multiply T_1 to $c_1 u_1 + c_2 u_2 + \dots + c_k u_k$. What I am doing is? I am multiplying this so, this was $T_1 \cdot 0$ which is 0.

So, what I am doing here is that I am looking at $c_1 T_1 u_1 + c_2 T_1 u_2 + \dots + c_k T_1 u_k = 0$. Now, what is $T_1 u_1$, what is $T_1 u_2$ and $T_1 u_k$? Fine. So, understand this very nicely this very very important idea.

(Refer Slide Time: 12:58)

So, if I want to look at $T_1 T_1$ has $A - \alpha_2 I$, it has $A - \alpha_3 I$, it has $A - \alpha_k I$. They commute so, at some a stage since they commute at some a stage, if I multiply this with u_2 this will give me 0 alright again when I multiply T_1 with u_3 . So, T_1

with u_1 T_1 with u_1 I do not know what that will be, but what I know is that T_1 with u_2 will be 0, because there will be somewhere where A minus α_2 of I will come. Similarly T_1 of u_3 will be 0, basically because A minus α_3 is there. So, what will happen is that all of them T_1 of u_k will be 0 alright.

So, all of them there will be 0 I do not know whether this will be 0 or not. So, we are claiming now you are claiming that T_1 of u_1 is not 0 that is more important that we are saying that its not 0, we have already shown that T_1 u_2 is 0 u_3 is 0 u_k is 0. So, what you are saying is that this is already 0 T_1 u_2 this is already 0. The only problem is that whether this is 0 or not so, let us look at that part. So, what our T_1 is T_1 had these terms.

So, the first term was A minus α_2 I , then there was A minus α_3 I and so on. A minus α_k of I am supposed to multiply this with u_1 , if I do this then what I get is that this part if I adequate I just leave it as it is for the time being. Now, this part gives me A u_1 A u_1 is nothing, but α_1 u_1 minus α_2

So, it will α_1 u_1 minus α_2 u_2 , this is what I will get just multiply it A u_1 is α_1 1. So, this is nothing, but A u_1 is α_1 u_1 and then α_2 u_2 . So, I can write it back as things like this and this is α_1 minus α_2 of u_1 again. This was a u_1 here α_2 of u_1 alright fine.

So, again this is a constant so, I can just put α_1 minus α_2 outside here. So, then I will get here A minus α_k of I so on till A minus α_3 of I times u_1 again this will give me just multiply it out you will get here, α_1 minus α_3 times u_1 . So, at each a stage what I am getting is that, we will just get its effect do the whole calculation what I will get is that I will get α_1 minus α_2 α_1 minus α_3 . So, on till α_k minus α_1 minus α_k of u_1 alright fine.

And we are taken that the α_1 α_2 α_k are distinct. And this implies that α_1 minus α_k is not equal to 0 for all k greater than equal to 2. And therefore, this vector is not 0 is that fine. So, that is what is important that all these vectors T_1 u_2 is 0 T_1 of T_1 u_3 is

0 and so, on till all of them are 0, only vector that is left out is this part, I know that T_1 of u_1 is not equal to 0.

So, what I get from here is that c_1 times some constant which is this number which is product of α_1 minus α_i i is equal to 2 to k times u_1 is 0 fine u_1 is the eigenvectors so, that is not 0 this is not 0. Because, α_i are distinct so, it implies that c_1 has to be 0 alright.

So, we have shown that now if I look at this part we have shown that in this part, that in this linear combination if I look at this linear combination c_1 is 0 you have shown. So, shown c_1 is 0 by applying T_1 alright. I can apply T_2 again to the whole thing to get c_2 is 0 and so on.

(Refer Slide Time: 17:09)

The image shows a handwritten mathematical derivation on a digital whiteboard. The derivation is as follows:

At the top, the equation $c_1 T_1 u_1 + c_2 T_1 u_2 + \dots + c_k T_1 u_k = 0$ is written. Below it, the text "Claiming: $T_1 u_i \neq 0$ " is written. To the right, a list of conditions is shown: $T_1 u_1 = ?$, $T_1 u_2 \neq 0$, $T_1 u_3 \neq 0$, ..., $T_1 u_k \neq 0$.

The main derivation starts with $(A - \alpha_1 I) \dots (A - \alpha_{i-1} I) (A - \alpha_{i+1} I) \dots (A - \alpha_k I) u_1 = 0$. This is simplified to $(\alpha_1 - \alpha_2) \dots (\alpha_1 - \alpha_k) u_1 = 0$. A note states: "Since $\alpha_1, \alpha_2, \dots, \alpha_k$ are distinct $\Rightarrow \alpha_1 - \alpha_i \neq 0 \forall i \geq 2$ ".

Below this, the text "Applying T_1 to" is written, followed by a box containing $(c_1 u_1 + c_2 u_2 + \dots + c_k u_k) = 0$. This leads to $c_1 = 0$ and $c_2 = 0$. The text "Applying T_2 to" is written, followed by a box containing $(A - \alpha_{k-1} I) \dots (A - \alpha_2 I) (A - \alpha_1 I) u_1 = 0$, which leads to $c_k = 0$.

So, let me write that now applying T_1 to $c_1 u_1$ plus $c_2 u_2$ plus $c_k u_k$ is equal to 0 implied c_1 is 0. If we apply T_2 to the same thing I will get c_2 is 0 and so on. So, apply finally, T_k and what was T_k if you remember T_k is nothing, but it is supposed to be A minus α_k minus 1 I A minus α_k minus 2 I so, on till A minus α_k minus 1 I , if I apply this matrix to this equation I will get that c_k is 0.

So, the idea is that each of these matrices they play some role as per as we are concerned is that ok. So, A minus α_k of I applied to u_k or not u_k alright u_j let me write u_j here, $u_j u_j$ this is 0 fine. And if I am looking at A minus α_j I of u_j this is not 0. If I is not equal to 0 alright that is very important, because of that we are able to get this is that ok, generalization of this idea.

(Refer Slide Time: 18:31)

Thm: Let $\alpha_1, \alpha_2, \dots, \alpha_k$ be distinct eigenvalues of A with geo multi of α_i as $n_i, 1 \leq i \leq k$. Then A has $\sum_{i=1}^k n_i$ linearly independent eigenvectors.

eigenvectors u_1, u_2, \dots, u_k L.I. set

Generalize u_1, \dots, u_{n_1} - L.I. $\dim(\text{Null}(A - \alpha_1 I)) = n_1$

$u_{21}, u_{22}, \dots, u_{2n_2}$ eigenvectors

$u_{k1}, u_{k2}, \dots, u_{kn_k}$ L.I. set of eigenvectors

$\{ u_{11}, \dots, u_{1n_1}, u_{21}, \dots, u_{2n_2}, \dots, u_{k1}, \dots, u_{kn_k} \}$ is L.I. set of eigenvectors.

If we pick $u_{11}, u_{22}, u_{32}, \dots, u_{k1}$ L.I.

Let $\alpha_1, \alpha_2, \dots, \alpha_k$ be distinct eigenvalues of A , with I do not know about algebraic multiplicity with geometric multiplicity of α_i as $n_i \leq m_i$, then A has $\sum_{i=1}^k n_i$ linearly independent eigenvectors is that ok.

So, what exactly we have shown in the previous theorem was that if I have got $\alpha_1, \alpha_2, \dots, \alpha_k$ I had u_1 here, u_2 here u_k eigenvectors u_1 eigenvector. So, I took any eigenvector u_1, u_2, \dots, u_k of α_1 to α_k , then they are linearly independent. Now, what we are doing in this theorem is we are trying to generalize. So, what you are saying is that if I pick here eigenvectors as u_{11} till u_{1n_1} because they are n_1 eigenvectors here.

So, n_1 dimension of $A - \alpha_1 I$ null space of $A - \alpha_1 I$ is equal to n_1 the sort you out assumption is so, I will get. So, many linearly independent eigenvectors here, I will get $u_{21}, u_{22}, \dots, u_{2n_2}$ eigenvectors fine. And here I will get $u_{k1}, u_{k2}, \dots, u_{kn_k}$ eigenvectors. So, what we know is that know since dimension is this implies that these are linearly independent here the dimension is n_2 . So, these are linearly independent similarly these are linearly independent alright fine.

What we are claiming here is that all of them. So, what we are claiming here that if I look at the set u_{11} till u_{1n_1}, u_{21} till u_{2n_2} so on till u_{k1} till u_{kn_k} , then this is linearly independent set of eigenvectors, this what we are claiming. And the idea of the proof is what I know is that if I just pick any one from the first set, any vector from the second set, any vector from the k th set then that is linearly independent because of the previous theorem alright.

So, they are linearly independent because of this part that, if I have any collection of eigenvectors corresponding to distinct eigenvalues, they are linearly independent. So, if I pick $u_{11}, u_{22}, \dots, u_{k2}$. So, if I pick. So, if we if we pick u_{11}, u_{22}, u_{32} so, on till u_{k1} you have picked this collection then, this is linearly independent because of they correspond to distinct eigenvalues alright.

And hence all of them there are going to give me some eigenvector or the other this what is given to me, they are eigenvectors. And since they are coming from distinct eigenvalues, they are linearly independent. And among themselves they are linearly independent, because I chose them to be linearly independent, because they are $n-1$ of them here $n-2$ here and $n-k$ here is that ok.

(Refer Slide Time: 22:48)

Con: Let A be an $n \times n$ matrix. If A has n distinct eigenvalues, then A is diagonalizable.

\Leftrightarrow A has n L.I. eigenvectors.

Example ① $A = \begin{bmatrix} 1 & 2 & 3 & 4 \\ 0 & 2 & 1 & 2 \\ 0 & 0 & 3 & 5 \\ 0 & 0 & 0 & 7 \end{bmatrix}$ \Rightarrow A is diagonalizable.

eigenvalues of $A \rightarrow 1, 2, 3, 7$ distinct $\Rightarrow A$ has 4 L.I. eigenvectors $\Rightarrow A$ is diagonalizable.

$A = \begin{bmatrix} 1 & 1 & 2 & 4 \\ 0 & 1 & 1 & 2 \\ 0 & 0 & 3 & 5 \\ 0 & 0 & 0 & 7 \end{bmatrix}$ Cannot make any statement without doing proper calculation.

\hookrightarrow $(1, 1, 3, 5)$ \rightarrow eigenvalue 1 is repeated.

So, you need to understand that if I have distinct eigenvalues I can do things alright. So, as a corollary of this as a corollary let A be $n \times n$ if A has n distinct eigenvalues, then A is diagonalizable, we are saying that it has n distinct eigenvalues. So, n distinct eigenvalues means there will be n linearly independent eigenvectors and what we saw was that whenever A is diagonalizable, if and only if it has n linearly independent eigenvectors alright.

So, this was same thing as or equivalent to saying that A was A is diagonalizable fine. So, what we are saying here is so, as a example or as an application of this idea, example look at this matrix A which is $\begin{pmatrix} 1 & 2 & 3 & 4 \\ 0 & 2 & 1 & 2 \\ 0 & 0 & 3 & 5 \\ 0 & 0 & 0 & 7 \end{pmatrix}$ alright. So, if I look at the eigenvalues of A they are going to be 1 2 3 and 7. Because, this is an upper triangular matrix with diagonal entries 1 2 3 7 these are distinct implies A has 4 linearly independent eigenvectors, implies A is diagonalizable.

So, this is the (Refer Time: 24:34) that we have that as soon as we know that something is upper triangular, it has distinct entries on the diagonal, then that matrix is diagonalizable alright. So, here you I know it is diagonalizable, but if I want to look at this matrix $\begin{pmatrix} 1 & 1 & 2 & 4 \\ 0 & 1 & 1 & 2 \\ 0 & 0 & 3 & 5 \\ 0 & 0 & 0 & 7 \end{pmatrix}$ cannot make any statement, without doing proper calculation alright.

So, I will have to calculate thing here because, I do not have any theorem with me which will say that this is diagonalizable, this may be diagonalizable this may not be diagonalizable, but you have to compute basically because here the eigenvalues are 1 1 3 5. So, there is an eigenvalue which is repeated eigenvalue A 1 is repeated alright. So, whenever we have that something is not repeated everything is nice otherwise there is a problem alright. So, that is all for now.

Thank you.
