Indian Institute of Technology, Kanpur
Lecture – 10
Strong Maximum Principle

(Refer Slide Time: 00:26)

Welcome to this lecture; in today's lecture we are going to talk about some applications of mean value (theorem). So, essentially what we are doing is this; let us do just a small revision. We had this equation the Laplacian of this equation is equal to 0; this is simple harmonic it is called the Laplace equation; the solutions are called harmonic functions. So, let us this is in Ω and u restricted to the boundary is some function g . Now, the question was this, so the question was is it well posed? Or maybe I can do that more general problem. Let say take a Poisson equation, let say f . Now, the question is, is 1 well posed well posed?

Now, you have more or less some idea, of what to do. See, essentially this Ω is can be any Ω ; it is may not be particularly a rectangle or a circle or sphere that is sort of thing, so it is not a very nice. So, if let me put it in this way, if Ω is not a nice domain; you do understand what I mean by nice. So, you know a usual domain, not a nice domain; then what happen? Separation of variable fails. So, essentially, I give you a crazy looking domain, I mean something like this let say something like this. Separation of variable, you cannot use separation of variable here; so, what do you do then? Let see the point is this.

For this sort of domain for there are most of the domains, which you can think of separation of variable will not work. And essentially what do you do, in those cases in those cases, we rely on we rely on your qualitative analysis qualitative analysis. So, let me give you a small remark here, you may have heard that Green's function; you can actually construct as Green's function. And you can use it to solve this sort of Poisson equation; so, this is called the Poisson equation if you remember. And so, you may have heard about it; we did not talk about this in this course. But you may have heard that there are functions called as Green's function, which you can use to solve this problem.

Of course, there are and for arbitrary domain not any arbitrary domain, but smooth arbitrary domain; we will talk about it later, what are the domains we are we can. But, for generally most of the domains we can actually construct Green's functions; you can show that there exist Green's functions which solve the Poisson equation that can be done. The problem is this that Green's function you can only show that that exist; you cannot actually find it to this function. So, here also the same thing is happening, you cannot find an explicit solution of this equation in any case. So, what do you do then?

So, in this case what we are doing? Without solving the equation, we are trying to find some properties of this solution. So, let say any this problem has some solutions; I want to find some properties of this solution. We have seen what are the properties we have seen till now properties? We have seen that this 1 admits a unique solution provided it exists. So, if you essentially see did not prove that there are solutions; but if you can show that there are solutions. Then we have showed that the problem admits a unique solution; this will remember we did in the earlier week. And moreover, for this problem for Laplacian u equals to 0; so harmonic functions.

If a function is harmonic, so any solution of this equation; what does it do? It satisfies this, mean value property. So, f over $B(x, r)$ u of y dy . Please do not underestimate this property. This is probably B is most fundamental property; you can think of some particular class of functions, so u of z ds z .

So, this is the mean value of property; this we have proved in last class. So, is now what we are going to do is I am going to show some more properties of this harmonic function. Once you

understand harmonic functions for Poisson equation, dealing with Poisson equation is much easier; so, we will only concentrate on harmonic function for now.

(Refer Slide Time: 05:20)

Properties of Harmonic Function :- ($\Delta u = 0$)

Strong Maximum Principle: Suppose $u \in C^2(\Omega) \cap C(\bar{\Omega})$ is harmonic within Ω

$$(i) \max_{\bar{\Omega}} u = \max_{\partial\Omega} u$$

(ii) If $\exists x_0 \in \Omega$ st $u(x_0) = \max_{\bar{\Omega}} u$ then u is constant provided

Ω is connected.

Note:- Property (i) implies the maximum is attained on the boundary.
It does not imply that the maximum is not attained in the

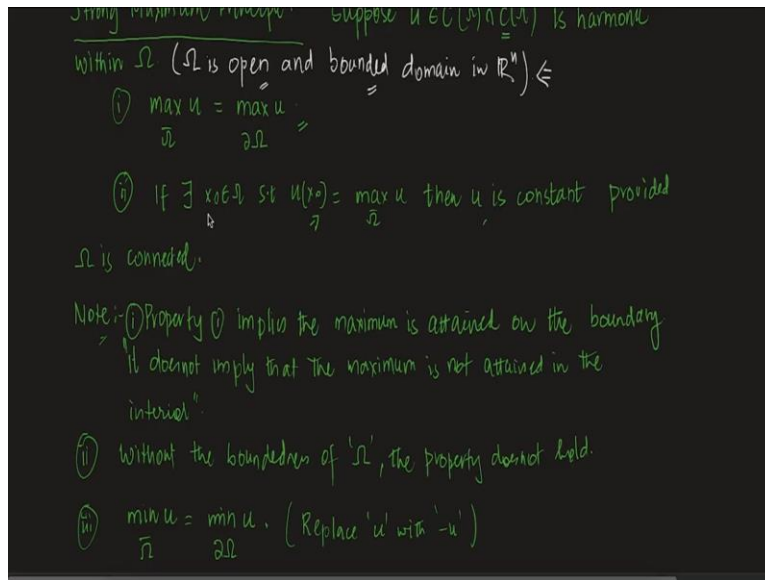

Note:- (i) Property (i) implies the maximum is attained on the boundary.
It does not imply that the maximum is not attained in the interior.

(ii) Without the boundedness of ' Ω ', the property does not hold.

$$(iii) \min_{\bar{\Omega}} u = \min_{\partial\Omega} u. \text{ (Replace 'u' with '-u')}$$

(iv) In this course we always assume Ω is connected.

Hence SMP implies that the maximum of a harmonic function can only be attained on the boundary of Ω .

So, what we are doing is we are going to prove some properties of harmonic functions. If you remember what are harmonic functions, these are functions for which Laplacian of u is equals to 0; so, properties of harmonic functions. So, the first important property very very important property is called the strong maximum principle strong maximum principle; so, what it says is this. It says that suppose u is in $C^2(\Omega) \cap C(\bar{\Omega})$. So, what we are doing is we are saying that the function, let say that is your Ω ; that is your Ω where we are talking about.

And so essentially here Laplacian of u is 0, so we are looking for properties of u . See, we have not solved this problem; of course you can find some solutions but not everyone. But the point is this, let say any u is there which in this Laplacian we can show Laplacian equals to 0. I am writing down some properties of those in some domain; so that is your Ω . Now, we are using u to be C^2 ; so, inside the double derivative exist and they are continuous inside. What about those on the boundary? Boundary double derivative may not exist, but boundary it actually coincides with the continuous function, $C(\bar{\Omega})$.

So, let say this is harmonic, harmonic within Ω ; so this is what we are assuming. Now, let me give you this, and then we will talk about that remark. First of all, what happens is if this happens, you can say that the maximum of u over $\bar{\Omega}$ equals to the maximum of u over the boundary. And number 2, what you can do? Is you can show that if here exist x_0 in Ω , such that $u(x_0)$ is equals to the maximum of u over $\bar{\Omega}$. So, essentially

what it is saying is the maximum of u is attained anywhere in the interior of the domain; then u is constant then u is constant provided ω is connected.

So, what exactly is this saying, let us understand first theorem. This is a very very important theorem; the proof is not very difficult. Once you prove the mean value property, but I mean later understand what is being this saying. In the first assumption, we have not assumed that the ω is connected, we did not assume that.

So, what we are saying is the maximum of u over ω is equal to the maximum of u over the boundary. So, basically what it is saying is the maximum u attains its maximum on the boundary. If you see that the first thing note, property 1 implies implies the maximum is attained on the boundary.

Property 1 does not say anything about the interior, it may happen that it is also there is a point where there in the interior also taking maximum. But you can always guarantee that there is a point this is the t ; one is not saying that t cannot attain the maximum in the interior, please understand this. It is saying that you can always find the point on the boundary of the domain, where the maximum is attaining; this is what we are saying. It may very well be happening, so it says it does not imply, that the maximum is not attained in the, let say it not attained in the interior.

So, it is not saying that the maximum cannot be attaining the interior; it may be, but it is saying that that you do not know whether that happens or not. All we know is it is always attaining on the boundary; this is being the first property note. The second property is this is very important; here I did not assuming anything on ω , so important thing.

So, let me put it I do not know maybe let us put it in quite, ω is open and bounded domain in \mathbb{R}^n . Here, please understand for a strong maximum principle to hold, this has to be open and bounded. This is very important why? Because we see if it is open, ω is closed; and it is a bounded domain.

So, you are looking at a continuous function on a closed bounded domain, which is a compact set. So, continuous function on a compact set attains its maxima; so that is why this maxima is here. Do you understand what are things? It is try to understand this thing; without this condition

this is very important. This condition you cannot guarantee that this happens; because it cannot even guarantee that the maximum is attained. So, let me put it this way without the boundedness of Ω ; the property does not hold, so that is true.

Now, let us give you an example, so let me give you an example; I will. Before that there is another property which we want to talk about, number 3. See, here I am saying the maximum is attained on the boundary that is what I am saying. I am not saying it is not attaining on the interior; I am still talking about 1.

You can also say that the minimum, see u is a continuous function; u is a continuous function on a closed bounded set. $U \Omega$ is open, $u \Omega$ bar is closed; so it is a continuous function on a closed and bounded domain. So, it attains a maxima and the minima, now the question is this, is the maxima is attained on the boundary; what does the minima is attained?

So, the minimum of u over Ω bar on the whole domain including the boundary Ω bar, is attaining on minimum of u over the boundary; this is also true. So, what you can say is the maxima and the minima is always attained on the boundary. How do we prove it? Just replace u with minus u . u satisfies the harmonic equation sorry the Laplace equation; so minus u also satisfies the Laplace equation. So, the Laplace equation the set of the solutions are it is a vector space. So, minus u is also satisfy this and you can just replace u with minus u ; and we can say it is a maximum can be replaced with a minimum.

Now, number 2, this is what is so important about the property 2? Property 2 is important because what it says is this; it connects the whole thing. So, it is saying that once you understand that Ω is connected most of the times; so please remember this thing I am not going to repeat this again. In this course in this course essentially we always assume Ω is connected; this is always assumed. But generally why so? You may ask that one why I am putting this two conditions separately. This condition the second property, what does it say? It says that if there is a maximum.

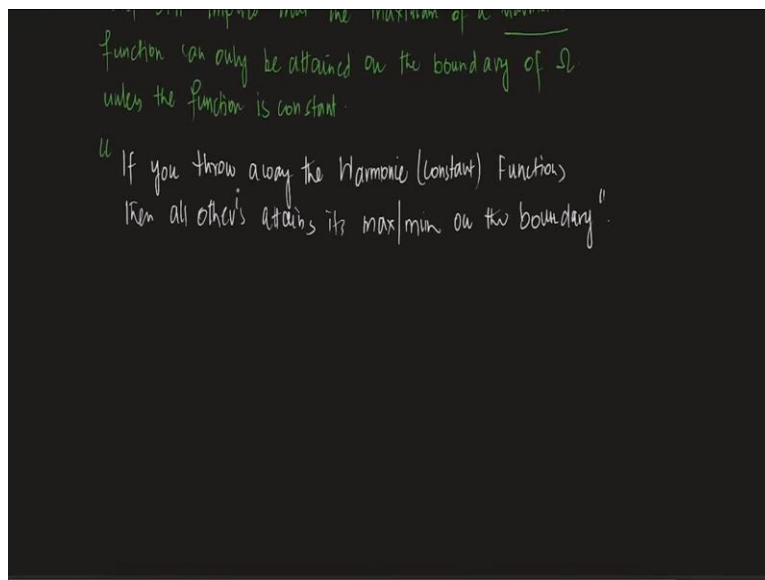

If maximum is attained in the interior, what it is saying is, in the earlier case it is saying that the maximum is attained on the boundary; it does not say anything about the interior; it may or may not happen on the interior. The second property is saying that if there is a point what the

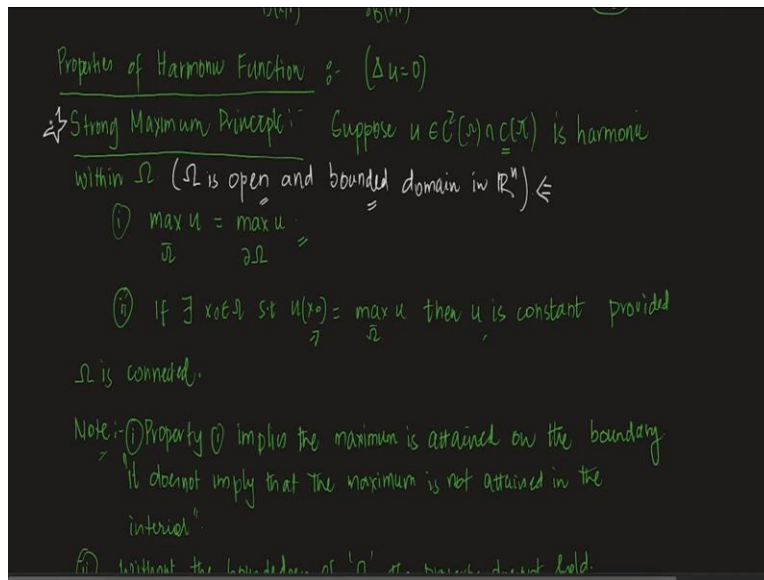

maximum is attained; then the function has to be constant. And this is true, if the domain is connected; but for our course we are always assuming Ω is connected. So, for our course we will always assume that the Ω is connected. So, basically hence the strong maximum principle, I will write it like this SMP Strong Maximum Principle.

SMP implies implies that the maximum the maximum of a harmonic function can only be attained on the boundary of the domain, boundary of Ω . So, clear is this clear, see unless the function is constant; is this clear. So, what it is saying? It is saying that it is saying if the maxima is attained on the somewhere in the interior; then the function is constant, provided that Ω is connected. Now, our course we are always assuming Ω is connected; so, connected or not is you always know that there is always the maxima on the boundary. And here it is saying if it is the interior point where the maxim is attained and then it is constant.

So, you can plus these two together and it says that the maximum of a harmonic function. The maximum of a harmonic function can only be attained on the boundary of the domain, until unless the function is constant. So, if we just show away that constant functions; all other harmonic functions have to attain.

(Refer Slide Time: 17:14)

So, it says let me put it this, if you if you throw away the harmonic constant harmonic functions constant harmonic functions; then all others attains, its maxima plus minima, on the boundary. I hope this is clear and you may think that I have taking too much time explaining these things. This is the most fundamental property of \mathbb{C} z; so mean value property which is always only satisfied by harmonic functions. This maximum principle we are using we are proving maximum principle using mean value theorem. But, maximum principle can be used; you can find maximum principle not only in Laplace equation, but also heat equation and we have heat equation also. So, let us write it down many other partial differential equation, so this is very important property; so, this a very very fundamental property. So, let me put it in a star kind of thing, so it is a star property, let us put it like this.

Very very important please remember this thing. So, this is strong maximum principle, here we are just doing it for a Laplace equation; later we will also used it for a heat equation also. But, for heat equation we will not do any not exactly the mean value property which we did. So, let us look at the proof of this.

(Refer Slide Time: 19:02)

Proof: We assume Ω is connected.

Let $x_0 \in \Omega$ with $u(x_0) = M := \max_{\bar{\Omega}} u$.

Set $0 < r < \text{dist}(x_0, \partial\Omega)$, the HVP says

$$M = u(x_0) \stackrel{\text{HVP}}{=} \int_{B(x_0, r)} u(y) dy \leq M \cdot \int_{B(x_0, r)} 1 dy$$
$$= M \cdot \frac{1}{M(B(x_0, r))} \cdot M(B(x_0, r))$$
$$= M.$$

unless the function is constant.

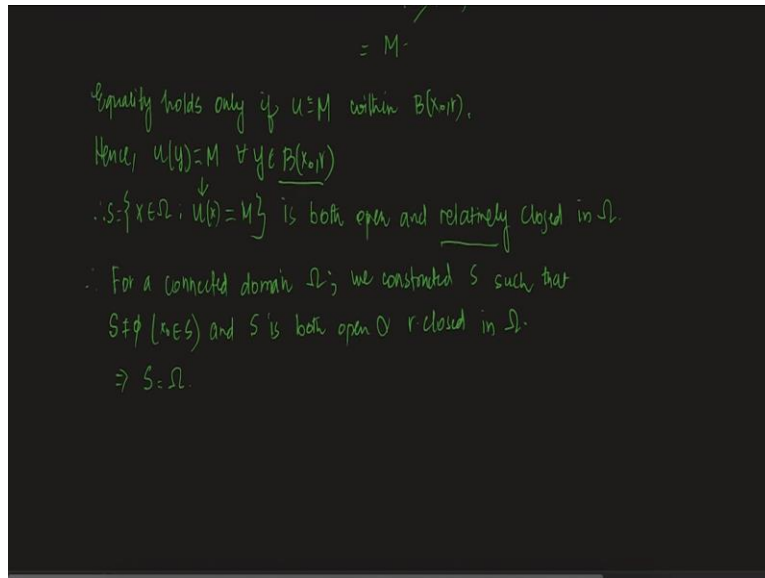

"If you throw away the Harmonic (constant) functions from all others, it's maximum on the boundary".

Proof: We assume Ω is connected.

Let $x_0 \in \Omega$ with $u(x_0) = M := \max_{\bar{\Omega}} u$.

Set $0 < r < \text{dist}(x_0, \partial\Omega)$, the HVP says

$$M = u(x_0) \stackrel{\text{HVP}}{=} \int_{B(x_0, r)} u(y) dy \leq M \cdot \int_{B(x_0, r)} 1 dy$$
$$= M \cdot \frac{1}{M(B(x_0, r))} \cdot M(B(x_0, r))$$

Proof, what is the proof of this is the proof is very easy. So, let us assume that so we are not we are not really interested in all this, you know omega is not connected, no no omega is connected. So, will assume we assume omega is connected omega is connected; and hence if omega is connected. What we are going to do is let will assume let x_0 is in x_0 is in omega with u of x_0 is M ; which is given by the maximum of u over omega bar. So, what we are saying is there is a point in the interior; so essentially what do we have to show?

I just have to show that u is a continuous on omega bar; so definitely u attains its maximum. Maxima and minima is always attained, somewhere either it is on the boundary or in the interior. We have to show it does not attaining the interior that is all; and then definitely it has to be on the boundary. So, let us just assume that there is a point x_0 , where it is taking the maxima. So, the maximum of u over where omega bar is M , where u of x_0 is M ; that is the value of u at the point x_0 . Now, what we are going to do is this set r , which is basically between; what we are going to do is this is something like this.

Let say x_0 is some point here, the distance between x_0 and boundary is this point. And we are choosing r which is like smaller than this; so, you can choose r like d by 2 let say, you can do that so that is your r . So, I am choosing a small ball, so essentially that ball will be on the domain like this. So, if that happens the mean value property the mean value property says

M ; this is equal to u of x naught that is what we have to assume. And that equals to integral over $B(x, r)$ of u of y dy .

U is a harmonic function this holds for harmonic function; we want to show that the strong maximum principle holds for harmonic functions. So, you see u of y dy on the ball $B(x, r)$; here r is a very small, you do not realize this thing. That is equal to u at point x naught, this is mean value property.

And this what happens what is the value of u on this ball? So, the maximum of u is always M ; I do not care whether if it is this ball or some other ball, it is always them. So, I can always dominate it is M times $B(x, r)$ dy ; this we can always do. So, what is this? This is M and this is 1 by the volume of $B(x, r)$; so I will write it like this.

You guys whoever for, if you guys know measure theory; then this is the measure of the ball. If you do not know, do not worry about it; just think of this as a volume of a ball. So, when you do it like this that 1 by volume of ball; and integral of dy that is the again the volume of the $B(x, r)$. So, this gets cancelled out and this is equal to M ; so this is clear. So, now what we are getting is we are going to get from here; that is integral of u over this ball; this is equal to M and less than equal to M . Thus, this so at this equality when does it holds? So, equality holds only u equals to M , within the $B(x, r)$.

This is a point where u is less than M , then this I mean you can please show this. You can dominate that thing with this thing; so, this will be greater than equal that M minus epsilon let say, at the measure of the ball. This cannot happen, you cannot show this is equal to M ; so please check this part that holds in only if u equals to M within $B(x, r)$. So, hence u of y is equal to M for all y in $B(x, r)$; is this clear? So, please check that u is equal to M , u has to be equal to M ; so, you can show that there are no points u less than M . So, let say there are for some epsilon u is M minus epsilon on this ball. You can actually dominate that you can use this thing to dominate that particular thing.

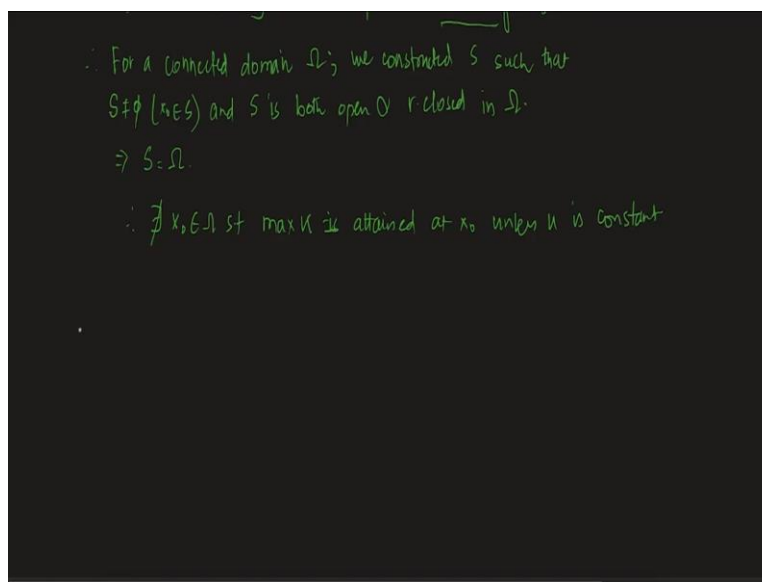

So, basically this will be greater than M minus epsilon times that whole thing; so, please do that part, you can show that this is it cannot be equal to M in that way. So, u of y equals to M , this is clear; now, what is happening is this. So, therefore the set x in Ω such that u of x equals to M ; this set is both open and relatively closed in Ω . Let me explain what I mean by

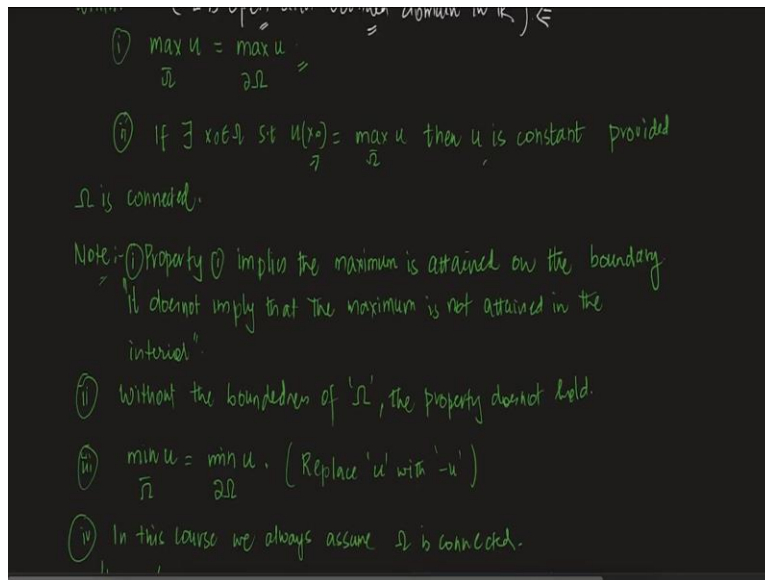

this thing. When I say it is relatively closed, of course this u is a closed set; sorry u is a continuous function and u is there looking at the values of u , level set of u , for the height M . So, this is in its own rights a closed set in \mathbb{R}^n ; it is a closed set in \mathbb{R}^n .

But, at the intersection of it is relatively closed, because this is we are looking with the intersection of ω this set; so that is why it is relatively closed in ω . And why it is open because we have shown that if we take a point there inside this set; then you can always have a ball of radius r when u is m ; so that is why it is open. So, basically you see here therefore for a connected domain for a connected domain ω ; we constructed this set, this set this S let us call it S . S such that S is non-empty of course it is; because we have assumed that this is there is a point where interior where this is happening.

We have assumed that there is a point x_{naught} , where M is attained; so essentially this x_{naught} point is always in S , x_{naught} is always in S . Further this happens and S is both open and relatively closed in ω ; so, all of this is happening. And since ω is connected what can you say, this will imply that S is equals to ω . Because you guys is, already know that in a connected domain, if you have a subset; it goes open and closed. Then the subset has to be either \emptyset or the whole set; it cannot be \emptyset , so it has to be the whole set ω .

(Refer Slide Time: 27:29)

So, hence there cannot exist a point x_0 in Ω such that the maximum of u is attained there. So, what we have shown? We have shown that S is essentially $\bar{\Omega}$; so basically we have shown that the maximum of u is attained on $\bar{\Omega}$. We proved this second part. It proved that if the maximum is attained in an interior point, then it has to be constant. That is what we showed. $S = \bar{\Omega}$, it has to be constant; so basically u is constant on the whole domain Ω , so the maximum of u is attained at x_0 unless u is constant. So, now so this is very good, so we learned this thing; as I have again explained that this is also true, if we assume that if we replace maximum or the minimum; so, the same thing happens.

(Refer Slide Time: 29:01)

$\therefore \nexists x_0 \in \Omega$ s.t. $\max u$ is attained at x_0 unless u is constant

Remark: Maximum Principle does not hold if Ω is unbounded. (Check)

Hint: Take $\Omega = \{x^2 + y^2 < 1\}^c$ (Exterior of the unit ball).
Choose a harmonic function in Ω to show S.M.P. does not hold.

Proposition: (Positivity) If $u \in C(\bar{\Omega}) \cap C^2(\Omega)$ and satisfies
 $\Delta u = 0$ in Ω
 $u = g$ on $\partial\Omega$.

where $g \geq 0$. Then u is positive everywhere in Ω if g is positive

where $g \geq 0$. Then u is positive everywhere in Ω if g is positive somewhere on $\partial\Omega$.

Proof: Harmonic functions attain its max/min on the boundary.

$\forall x \in \bar{\Omega}, u(x) \geq \min_{\partial\Omega} u = \min_{\partial\Omega} g \geq 0$

Hence, u is non-negative in $\bar{\Omega}$. (We have to show that $u(x) > 0$ in Ω)

Let, $\exists x_0 \in \bar{\Omega}$ s.t. $u(x_0) = 0$.

Then, u attains its minimum at an interior point.

S.M.P. $\Rightarrow u$ is constant in $\bar{\Omega}$.

Now, let me make a small remark here, remark so remark. Maximum principle does not hold; whenever I say maximum, see there is nothing maximum here; which you can call it a minimum principle also, same thing. Maximum principle does not hold if omega is unbounded; so of course maximum may or may not be attained that is one point.

Even though maximum may be attained, then also it may not hold. So, let we have to check this part. It is a very simple example; take the exterior of the domain; so it will give some hint. I could have gave you the example, but you have to do it yourself. Hint: take omega to be the exterior of the domain $x^2 + y^2 < 1$ compliment of this thing. Take that to

be your ω ; so essentially what I am doing? I am taking the exterior of the unit ball. So, this is the exterior of the unit ball exterior of the unit ball; that is your domain. Now, choose a function choose a function harmonic function.

Now, choose a harmonic function, of course not a constant; harmonic function in ω to show maximum strong maximum principle does not hold. Please do it yourself, find a harmonic function; it does not for which there will be a similar problem in assignments like this. But, when you are doing this thing, this thing try to find.

Now, let me give you another property so of harmonic function. So, now we are going to use this maximum principle to show some other properties, so properties. This property is called positivity, so what does it says? It says that if u is in $C(\bar{\omega}) \cap C^2(\omega)$; and satisfies satisfies Laplacian u equals to 0 in ω .

And u equals to g on the boundary; let say this it satisfies this. So, basically you are looking at a Laplace equation, but on the boundary it is g ; where g is greater than equals 0. Then you can say u is positive everywhere in ω , if g is positive somewhere on the boundary. So, what it is saying is this, it is a very easy property. It says that you look at a Laplace equation and u equals to g on the boundary. Of course, it is given that g is greater than equal to 0, what it is saying is this please realize this thing. You take a point, if you can show that there is one point on the boundary, where g is positive.

It is saying that just showing one point on the boundary where g is positive; it is enough to show that u is positive everywhere in ω . So, this is the very important property you realize this thing; how can you do that? Take 5 seconds, think about it. So, I think it is most of you got it; so let me give you a short proof; there is nothing to prove but. So, let us look at the proof of this theorem; what it does it take to prove this thing. So, essentially you see this is a harmonic function harmonic functions attains its maxima plus minima on the boundary; that is what we learned boundary.

Now, g is greater than equal to 0, so $u(x)$ for for all x on the closure of ω , $u(x)$ is greater than equals to the minimum of u on the boundary $\partial\omega$, which is definitely true. Because you see $u(x)$ is always greater than equal the minimum of u over $\bar{\omega}$. And that is minimum of u over the boundary; because the maximum is always attaining the on the boundary

using the first property. So, now this is equal to the minimum of Δu over $\bar{\Omega}$, because u is on the boundary; so, and g is always greater than or equal to 0. So, the minimum of a non-negative function is always non-negative.

So, u of x here there hence, hence u is non-negative in $\bar{\Omega}$; now you have to show that if g is positive, somewhere u is positive everywhere. So, let there exist x_0 such that u of x_0 is 0 in Ω ; so x_0 in Ω such that this is 0. What I am doing is this I have to show that u is always strictly greater than 0 in Ω .

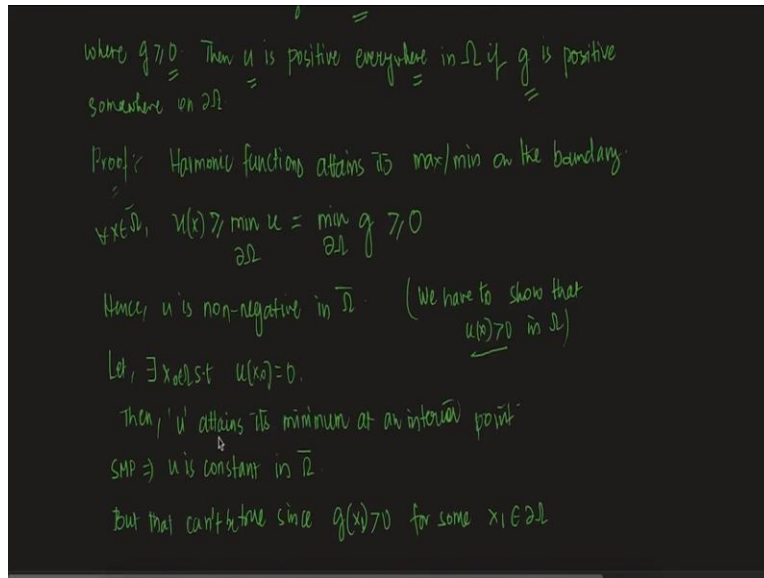

So, this is what, so we have to show we have to show that u of x is strictly greater than 0 in Ω ; this is what we need to show. So, let say there is a point x_0 where u of x_0 is equal to 0. If that happens then what you can say is this; then u of x is always greater than or equal to 0 in $\bar{\Omega}$. And there is a point where u is taking 0 in the interior.

So, again u attains its minimum at an interior point; so, this is contrast about the statement. We are assuming that if u is; we have to show u is greater than or equal to 0. Let say there is a point x_0 in Ω , where u is equal to 0. If that happens then u is in non-negative, it means that u is attaining minima which is 0, at a interior point x_0 . What is that therefore strong maximum principle that will imply u is constant in $\bar{\Omega}$; that is what strong maximum principle says in that case. So, u is constant in $\bar{\Omega}$.

(Refer Slide Time: 37:15)

Then, u attains its minimum at an interior point
SMP \Rightarrow u is constant in $\bar{\Omega}$.
but that can't be true since $g(x) > 0$ for some $x_1 \in \partial\Omega$
 $[u(x_1) = g(x_1) > 0]$
 \uparrow
- Hence a contradiction

Property:- (Positivity) If $u \in C(\bar{\Omega}) \cap C^2(\Omega)$ and satisfies
 $\Delta u = 0$ in Ω
 $u = g$ on $\partial\Omega$.
where $g > 0$. Then u is positive everywhere in Ω if g is positive
somewhere on $\partial\Omega$.
Proof: Harmonic functions attains its max/min on the boundary.
 $\forall x \in \bar{\Omega}, u(x) \geq \min_{\partial\Omega} u = \min_{\partial\Omega} g > 0$
Hence, u is non-negative in $\bar{\Omega}$. (We have to show that $u(x) > 0$ in Ω)
Let, $\exists x_0 \in \bar{\Omega}$ s.t. $u(x_0) = 0$.
Then, u attains its minimum at an interior point.

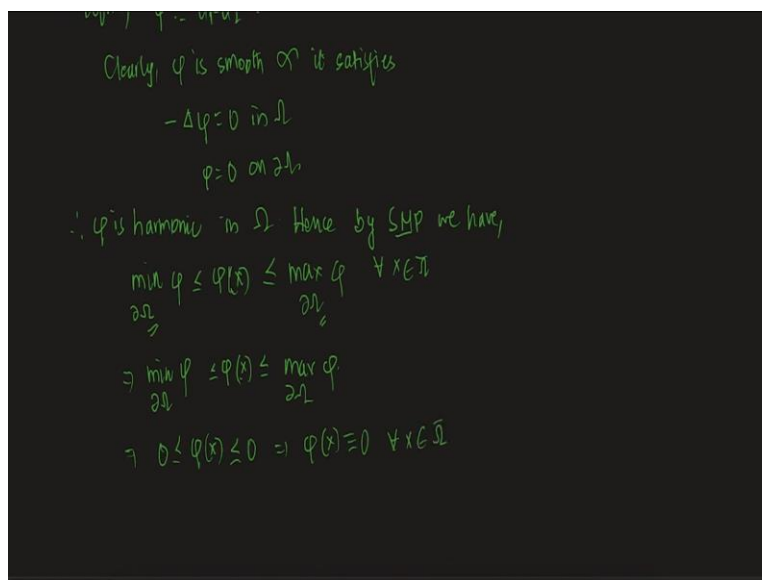

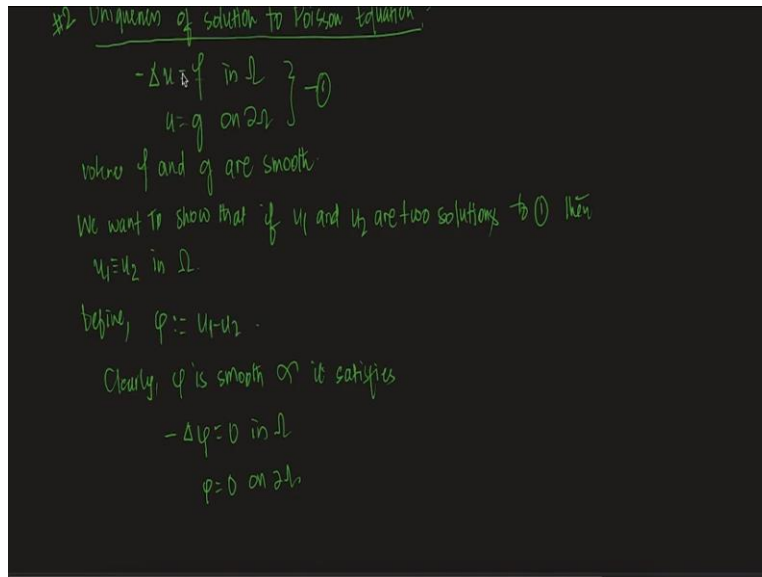

But, that is not true since that cannot be true; let me put it in this way. Cannot be true since g of x is greater than 0; let say g of x_1 is greater than 0, for some x_1 in the boundary. What is happening is this. We already know that g is positive somewhere on the boundary; so let say there is a point x_1 , where g is greater than equals greater than 0 strictly greater than 0. Now, if g is strictly greater than 0 at point x_1 on the boundary; so why because if g is strictly greater than 0 on the boundary x_1 , then u at the point x_1 is g at the point x_1 . Because u and g are same on the boundary; so, this is strictly greater than 0.

You are saying that u is constant on ω ; yes, u is constant along in ω . There is a point on the boundary where u is positive; so, u has to be positive everywhere. But again you showed that on the there is a point on x_1 where u is 0; so that is a contradiction, is it clear. What we did is this, let me explain again. We have to show that this is positive everywhere in ω , strictly positive; let say there is a point where u of x naught is 0 in the interior of the domain. If that happens strong maximum principle says what? It has to be constant in ω . If it is constant in ω , our condition is there is a point x_1 on the boundary where g is positive.

If that happens what happens at the u at the point x_1 is g at the point x_1 , which is positive. So, basically you showed the point x_1 on the boundary where u is positive; and you have showed a point x naught in the interior, where u is 0. So, but you are always strong maximum principle is saying that u is constant in ω . So, that cannot happen a constant function cannot take 0 and 1; 0 at some point and 1 on that point, hence a contradiction. I hope this is fine contradiction

and so we have proved that if g is positive somewhere at one point; then u is positive everywhere, very very important theorem.

(Refer Slide Time: 39:58)

So, another very important property is the uniqueness of solution to Poisson equation. Here what I am doing is this, so this is property 2; that is your property 2. This uniqueness of solution for the Poisson equation what I mean by this is? Let say you are given this equation in omega and u equals g on the boundary. Of course, where f and g are smooth assume that; so, basically infinity differential let us assume this thing. We want to show that we want to show that if u_1 and u_2 are two solutions, distinct solutions, or different solutions to 1; then u_1 is equivalent to u_2 in omega.

So, if you remember last in one of the lectures, we have already covered this thing; that there is a uniqueness solution for this problem.

But now will do it again in a very, we proved earlier it easy in the integration by parts; here, will use the maximum principle to prove it. So, let say so define this is just an application of maximum principle that is all and nothing else. You just define ϕ to be u_1 minus u_2 ; so clearly ϕ is smooth and so ϕ is u_2 in this case. If u_1 and u_2 are ϕ^2 , ϕ is u_2 and it satisfies, this is, and it satisfies. So, let say let me put it like minus or plus; it looks nice, it just a technical thing, nothing problem no problem; you can use Laplacian also. But it satisfies minus Laplacian of ϕ is 0 in Ω , and ϕ equals to 0 on the boundary. I hope this is fine.

So, ϕ is equals to u_1 minus u_2 ; u_1 and u_2 both satisfies this equation. So, the difference of those two will also satisfies this equation because of the linearity of the harmonic function. If that happens therefore ϕ is harmonic in Ω ; here what is happening is these functions are not harmonic. This is not a harmonic function, but since I am taking the difference of those two; so, the difference is harmonic.

So, ϕ is harmonic function such that ϕ is 0 on the boundary. So, what do we hence by strong maximum principle we have; one thing again I am saying this thing again and again, we will always assume Ω is open, bounded and connected. This is always assumed; in this course we are always going to assume this thing Ω is open, bounded and connected. So, my strong maximum principle what do you have? You have the minimum of u over $\partial\Omega$ is less than equal; so over $\bar{\Omega}$, but then that is also in the $\partial\Omega$. So, this is u of x , u of x is always lies between this; maximum of u over the boundary, I hope this is fine. U is always in between the maximum and the minimum of u over; so, this holds this holds for all x in $\bar{\Omega}$. So, maximum of if you replace this thing with $\bar{\Omega}$, this thing is $\bar{\Omega}$.

So, u of x will lies, between the minimum of u over the $\bar{\Omega}$ and the maximum of ϕ over $\bar{\Omega}$. Strong maximum principle says that the minimum of u over $\bar{\Omega}$ is on the boundary; and again, the maximum is also on the boundary. So, u is lies between minimum of u over the boundary and the maximum of u over the boundary. So, what is the minimum, so this means that this is basically minimum of ϕ over $\partial\Omega$, less than equal I think it is already

done. So, maximum of ϕ over $\partial\Omega$; because u is ϕ on the $\partial\Omega$. Now, you see ϕ is identically equals to 0 on the boundary; so, this is less than equal u .

Sorry, I have to change, this is not u , we have to do it for ϕ ; I am sorry for this thing, this is ϕ . ϕ is harmonic so this is ϕ of x , maximum of ϕ ; so, this is again ϕ and that is ϕ . So, what does it means? It means that ϕ of x , it means that ϕ of x is greater than equals 0; and again it is less than equals 0. So, that will give you ϕ of x is identically equals to 0, for all x on the closure of Ω .

(Refer Slide Time: 45:40)

$$\begin{aligned} \Rightarrow \min_{\partial\Omega} \phi &= \phi(x) \leq \max_{\partial\Omega} \phi \\ \Rightarrow 0 &\leq \phi(x) \leq 0 \Rightarrow \phi(x) = 0 \quad \forall x \in \bar{\Omega} \end{aligned}$$

Hence, $u_1 = u_2$ in $\bar{\Omega}$ and uniqueness follows.

$$[u(x) = g(x) > 0]$$

- Hence a contradiction

#2 Uniqueness of solution to Poisson Equation:

$$\left. \begin{aligned} -\Delta u &= f \text{ in } \Omega \\ u &= g \text{ on } \partial\Omega \end{aligned} \right\} \text{ (1)} \quad (\Omega = \text{Open, bounded and connected})$$

where f and g are smooth.

We want to show that if u_1 and u_2 are two solutions to (1) then $u_1 = u_2$ in Ω .

Define, $\phi := u_1 - u_2$.

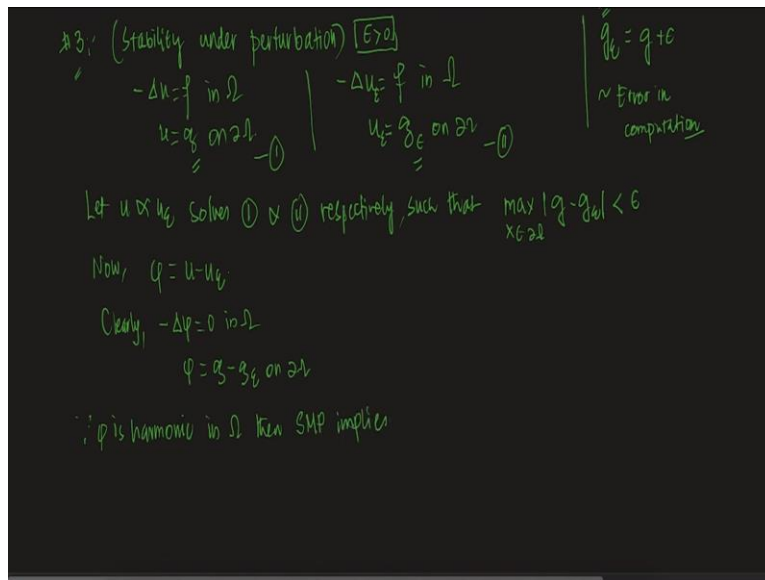

Clearly, ϕ is smooth & it satisfies

$$\Delta \phi = 0 \text{ in } \Omega$$

And hence u_1 is identically equals to 0 is identically equals to u_2 in Ω and uniqueness follows. So, why I gave you this application of this strong maximum principle uniqueness, because we already did uniqueness; but again I am doing it, because I want you to understand that for other problems of the ϕ .

Most of the times other methods which I showed you using integration by part showing uniqueness that may or may not work. You understand what I am saying? That may or may not work all the time. Maximum principle is for operator for some particular equation, which can show maximum principle; then there is a good chance that this sort of equation will hold. I mean you can cut out the uniqueness provided the function is linear; function is the operated with linear.

(Refer Slide Time: 46:43)

$$\varphi = g - g_\epsilon \text{ on } \partial\Omega$$

$\therefore \varphi$ is harmonic in Ω then SMP implies

$$\varphi(x) \leq \max_{\partial\Omega} \varphi \quad \forall x \in \bar{\Omega}$$

$$\Rightarrow |\varphi(x)| \leq \max_{\partial\Omega} |\varphi|$$

$$\Rightarrow |u - u_\epsilon| \leq \max_{\partial\Omega} |g - g_\epsilon| < \epsilon$$

$$\Rightarrow \max_{\bar{\Omega}} |u - u_\epsilon| < \epsilon$$

Hence, For small change in boundary data, the change in solution is also small. More precisely it is bounded by the error in the boundary data.

Ex: (Stability under perturbation) [Ex 2.1]

$$\begin{array}{l|l} -\Delta u = f \text{ in } \Omega & -\Delta u_\epsilon = f \text{ in } \Omega \\ u = g \text{ on } \partial\Omega & u_\epsilon = g_\epsilon \text{ on } \partial\Omega \end{array} \quad \begin{array}{l} g_\epsilon = g + \epsilon \\ \sim \text{Error in} \\ \text{computation} \end{array}$$

Let u & u_ϵ solve ① & ② respectively, such that $\max_{x \in \partial\Omega} |g - g_\epsilon| < \epsilon$

Now, $\varphi = u - u_\epsilon$

Clearly, $-\Delta \varphi = 0$ in Ω

$$\varphi = g - g_\epsilon \text{ on } \partial\Omega$$

$\therefore \varphi$ is harmonic in Ω then SMP implies

$$\varphi(x) \leq \max_{\partial\Omega} \varphi \quad \forall x \in \bar{\Omega}$$

Let see give you another very important property number 3; so the stability under perturbation. What stability under perturbation says is this; says you have equation in omega and equals g on the boundary. So, this is the equation which you already had; so let say we have a phenomena, which you have somehow in a modeled; and you have got something like this and let say why measuring. The next time again you are doing the same thing; you guys know that experiments have to be carried out many times not to get a reliable data. So, again you are doing the same experiments but definitely there is difference in measurement; so, there is a slight change in measurement.

So, the source term is same source term is same; this is f in Ω . But the data which you are going to get on the boundary that is different. So, let say this g is getting transferred to g_ϵ on the boundary; so, we call it u_ϵ , so this is an epsilon perturbation. You solved this problem 1, 2; let u and u_ϵ solves 1 and 2 respectively.

So, what I am saying? I am saying that both u and u_ϵ solve the same problem in Ω Laplacian. So, they satisfies $\Delta u = f$ and $\Delta u_\epsilon = f$. u and u_ϵ are both satisfies the same equation; but on the boundary u is g and u_ϵ is g_ϵ on the boundary, that is the difference.

So, g_ϵ can be for example you can think of g_ϵ to be, this for an example; it can be else also something else. So, think of this as g plus epsilon something like this; so, basically you are just taking a small perturbation. This is think of physically as the error in computation, think of this as error in computation.

So, basically you have this respectively such that now this error; you are measuring the same thing. But it may happened that the measurement is slightly off; so basically difference between g_ϵ and g is very small, so such that the maximum of $g - g_\epsilon$ that is less than epsilon itself. So, which u_ϵ positive, let say that is given to you.

So, the maximum and ϵ Δu_ϵ ; so, if you take the maximum of $g - g_\epsilon$ that is very small. So, what I am doing? I am assuming that while doing this measurement on the boundary; the error is extremely small. So, basically the difference between g and g_ϵ for every the maximum of that is always bounded by epsilon; we are assuming this thing. Now, ϕ you are defining it by $u - u_\epsilon$. Clearly, $\Delta u = 0$ in Ω , and ϕ is equals to $g - g_\epsilon$ on the boundary. So, what this is gives you is the following. U of x it means that the u , so by strong maximum principle this happens.

ϕ is a harmonic function, so therefore since ϕ is harmonic in Ω harmonic in Ω ; then strong maximum principle implies ϕ of x . This so what I am trying to say is this always less than equal the maximum of ϕ on the boundary, for all x in Ω . That is the maximum principle; so it says that the maximum is attained on the boundary. That will imply that ϕ of x , so mod of ϕ of x ; I can say this thing is less than equal maximum of mod ϕ over $\partial\Omega$, I

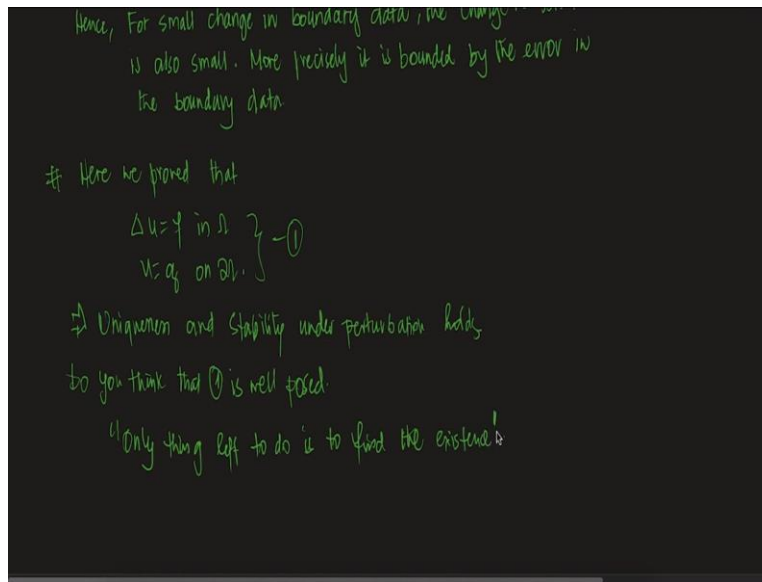

can say this. So, you see what will happen is this mod phi of x is u minus u epsilon; this is less than equal maximum of del omega mod phi g minus g epsilon.

So, basically you see g minus g epsilon is on the boundary; so I am just replacing this with this. And this is given to be less than epsilon. So, what this said is this if you change the initial data, data on the boundary a little bit; the change in the solution is also going to be bounded by that similar error.

That implies that the maximum of mod u minus u epsilon, and over omega bar; this is less than epsilon. So, hence what does it says? For let me put it this way, for small change in boundary data boundary data the change in solution the change in solution in this change, the maximum of u minus u epsilon.

Change in solution is also small; more precisely more precisely it is bounded by the error; error is in epsilon error in the boundary data. I hope this is fine; you have understood, so what it is saying is this. If you change your boundary data a little bit and the change is given by maximum of g minus g epsilon is less than epsilon. If that happens then your initial solution the solution u minus u epsilon; what is change in the solution? That change is also bounded by epsilon. So, little change in boundary data also changes the solution a little bit; so that is expected. So, by doing this uniqueness theorem and the stability under perturbation, we have actually did, two things.

(Refer Slide Time: 54:22)

So, here we proved that Laplacian u in ω , u equals to g on the boundary, for this equation; that is 1. So, uniqueness and stability under perturbation under perturbation holds; so we have proved it. So, we proved this particular thing for this equation, for this equation. Now the question is this now the question is this, so do you think do you think that 1 is well posed? So, if you remember what are the properties of well posed. The first of all you have to show that the existence, uniqueness and then the stability. We have proved the uniqueness on stability; but we did not prove the existence.

So, essentially the only thing left only thing left to do is to find the existence; and this is the difficult question in this case. And this will do it in the next week, but this week we continue to talk about more properties of harmonic functions. So, with this we are going to end this particular lecture.
