Laplace Equation

(Refer Slide Time: 00:14)

Laplace Equation :-
 Given a general linear PDE of the form (2nd order)

$$a u_{xx} + b u_{xy} + c u_{yy} + d u_x + e u_y + f u + g = 0$$
 where $a, b, \dots, g \in C^\infty(\mathbb{R}^2)$

where $a, b, \dots, g \in C^\infty(\mathbb{R}^2)$
Canonical Form :-
 "Under a suitable coordinate system (x, y) gets reduced to either of the following

- (i) $W_{xx} + W_{yy} + L(W_x, W_y, W, x, y) = 0$ — Elliptic
- (ii) $W_x - W_{yy} + L(W_x, W_y, W, x, y) = 0$ — Parabolic
- (iii) $W_{xx} - W_{yy} + L(W_x, W_y, W, x, y) = 0$ — Hyperbolic

where $L(\dots)$ are the lower order terms.
 "Please choose a suitable textbook ex "Myint - Tebrot" to review it"

Today let us talk about Laplace Equation. Now, in the first few lectures we have talked about first order equation. So, ut plus ux equals to that sort of equation, transport equation, work dot equation that sort of thing. But now, we are transitioning into the second order equation. Why Laplace Equation? Let us understand this thing first why Laplace Equation. See, the point is this

is the most basic second order equation of elliptic type. If you remember from earlier PDE courses, what happens is most of the, if given a general linear PDE of the form so second order how does it look like?

If you remember, it will look like this $a u_{xx} + b u_{xy} + c u_{yy} + d u_x + e u_y + f u = g$, I am not writing all of this, but a depends on xy , so, I am talking two dimensions and $b u$ of xy plus $c u$ of yy plus $d u$ of x plus $e u$ of y plus $f u$ plus let us say g equals to 0, that is a expression. So, all of these, here all of these coefficients a , b , c , these are all as in the, I am not writing all that. So, let us just do that all of these coefficients g these are all continuous, let us say these are smooth coefficients in \mathbb{R}^2 . So, that depends on x and y where a , b and all of these is in say infinity \mathbb{R}^2 .

Now the point is this, if you remember the canonical form, so the canonical form of this particular general equation, canonical form. I hope you understand so what I meant by this is see any second order linear PDE can be written in this form. Canonical form let us say that is your 1, let us say that is your star, it is 0 so let us call it star. So canonical form what it does is actually if you in a different in a more suitable coordinate system, so, what it does is under a suitable coordinate system, under the suitable coordinate system star gets.

So, under the suitable coordinate system star gets reduced to either of the following. So what it is, it is either $W_{xx} + W_{yy}$ plus some lower order terms, lower order terms containing W_x , W_y and W_{xy} that is equal to 0 or $W_{xx} - W_{yy}$ plus lower order terms containing W_x , W_y , W_{xy} equals to 0. Or you can have this form number 3, $W_{xx} - W_{yy}$ plus some lower order containing W_x , W_y , W_x and y .

What this canonical form does is, it does not change the nature of the equation. If you remember if you look at the discriminant of this equation and depending on the sign of the discriminant if it is negativity (< 0) (4:39), if it the positive, it is that the hyperbolic problem and if it is 0 it is a parabolic problem. Depending on that nature, if you do one suitable coordinate change, coordinate change then what happens is you can reduce this to something like this. This particular equation is an example elliptic equation. This equation is an example of a heat equation or a parabolic equation. And this equation is an example of a hyperbolic equation.

Let us understand what I meant by this. So, let me recall what I am doing, see, essentially we have a linear second order PDE which looks like this, all the coefficients are smooth this is what

we are assuming. What canonical form does it? See, this is in some coordinate system x and y , you can change the coordinate system to uv . So, here you can change xy to uv but it does not matter, these are all variables. You can right xy you can right uv . So essentially, under the new coordinate system, you can actually change a star to one of the following expression.

So let us say if this star is a elliptic equation to begin with, there is a change of coordinate, which will actually carried from this to this, this is much easier to solve this expression. So essentially, we are only interested in the higher order terms, lower order terms, I mean, those we can handle, higher order terms. So it will look like W_{xx} plus W_{yy} , that is elliptic problem. Again, if the original problem is a parabolic problem, under the change of variable, it will look much simpler, it will look like W_{xx} minus W_{yy} plus lower order term.

So, essentially, this is also a lower order term, but I am just writing it in this way just to make it look special, so, familiar just is like a heat equation, so that is parabolic form. Otherwise, you can just take this W_x over here also it is not a problem. And W_{xx} minus W_{yy} plus L of this is equals to 0 that is a hyperbolic form. So essentially this is like a whole equation form, two second order terms plus lower order terms like this. So, where let me put it like this, where L of are the lower order terms.

Now, so, let me make a small remark. I am assuming here that this is an advanced speaking course I am assuming that you guys know all of this, if you do not know please chose a suitable textbook. Whatever you want because most textbook contains this thing. Yes, please choose a suitable textbook for example, Myint and Debnath to review it.

See, this all thing, which I said if you guys are familiar with this thing, there is absolutely no issue is there. If you are not, then obviously you can just choose any textbook you want, I mean, this is just an example, Myint and Debnath, Partial Differential Equation this book, you can just look at that book and just review this whatever I said is not very difficult thing to do. Now, what is the point of all of this, the point of all of this is, see if we want to study most linear equations, you do not need to know, you understand you do not need to know how to solve a general equation like this. All you need to know is how to solve this three prototype equation.

If you know how to work with this three prototypes you are done, because ultimately any linear equation can be reduced to something like the second order. Any linear second order equation

can be reduced to one of these three forms. So, if you can just study these three forms, these are the fundamental forms, if you can just study these forms. So basically, we call these an operator L of W is W_{xx} plus W_{yy} . How these operators behave? Then we are done. So then we can actually work out our problems.

(Refer Slide Time: 09:10)

Define $L(u) := u_{xx} + u_{yy}$ is a linear operator
 So $L : C^2(\Omega) \rightarrow C(\Omega)$ is a linear second order operator
 Laplace Equation:- $\nabla u = (u_{x_1}, u_{x_2})$
 $\Delta u = \text{div}(\nabla u) = u_{x_1 x_1} + u_{x_2 x_2} + \dots + u_{x_n x_n} \Rightarrow \text{div}(\nabla u) = u_{xx} + u_{yy}$
 Poisson Equation:- (x_1, x_2)
 $-\Delta u = f$
 Here, $x \in \Omega (\subseteq \mathbb{R}^n)$ ($x = (x_1, x_2, \dots, x_n)$)

So, let us start by first of all, with a example. So, we define L of u , so, this is what I mean by an operator. Define L of u to be U_{xx} plus U_{yy} . Before I move on doing anything, I just want you to take 15 seconds, take 15 seconds and think about if what is L ? So L is supposed to as you can understand, it is kind of a function right is taking something and putting it into something, which is taking a function and giving back another function which looks like this. So can you tell me where is L defined from, just take 10 to 15 seconds and just think about it.

So let me just tell you where it is. See, L is an operator what I mean by operator here. So, L is a linear operator, what do I mean by a linear operator, what I meant by this is essentially see it is taking value from some vector space u . See if I am taking a u U_{xx} and U_{yy} has to be satisfied. So, u have to be accessed twice differentiable. So, it is C^2 or whatever domain it is yeah, I do not care some domain let us say Ω , I am starting out with an Ω which is a subset of \mathbb{R}^2 .

So, L is from $C^2 \mathbb{R}^2$ I mean you are choosing an element of twice differentiable element and it is giving back U_{xx} plus U_{yy} , if u is twice differentiable U_{xx} is continuous and U_{yy} is continuous the sum of two continuous function is continuous. So, it is giving you back something like this.

So, L from is a linear of second order operator. This is what I mean by operator. So, see this is also a function, but in a special way. What is so special about it, that is not taking element from any ordinary set, but a vector space of functions, it is taking element from vector space of functions.

Now, let us look at where all of this comes from. So, let us look at some physical motivation. So, before I do this let us do put some name to this particular operator. So, Laplace Equation, Laplace Equation, if you are looking at equation which looks like this Laplacian of u that is given by divergence of gradient u . If you remember gradient u is let us just start with two dimensions do not worry about anything, it is exactly the same.

Let us just start with two dimensions. So, in two dimension gradient of u is U_x and U_y . So divergence of gradient of u that is U_{xx} plus U_{yy} . So this is the U_{xx} plus U_{yy} . That is your Laplacian. Now, there is something this equation, this is not an equation anymore, I mean this is just an operator, now this if it is 0 equals to 2 then it is called the Laplacian equation.

Now, we also talk about a similar equation which is called the Poisson Equation. So, the name is Poisson Equation, this is I mean most probably I am not 100 percent sure, but Poisson is just is like a fish in French. So, the equation looks like this minus Laplacian of u minus there is nothing special about minus you can write it, may not write it, this is just in front mentioned minus Laplacian of u equals to f that is called a Poisson equation.

Here we will assume x is in from ω which is subset of \mathbb{R}^n . So, what I meant by x is an $n \times 1$, x_1, x_2, \dots, x_n . I have used a something. So, let me change this thing. So, maybe, let me do it for, from now on I will do it for \mathbb{R}^n itself. Actually, this is the problem, see I should write it like this. Let me change this part. So in two dimension it will look like this, $x_1 x_1, x_2 x_2$, so essentially your, I mean, $x_1 x_2$, so I am just writing a tuple in \mathbb{R}^2 as $x_1 x_2$.

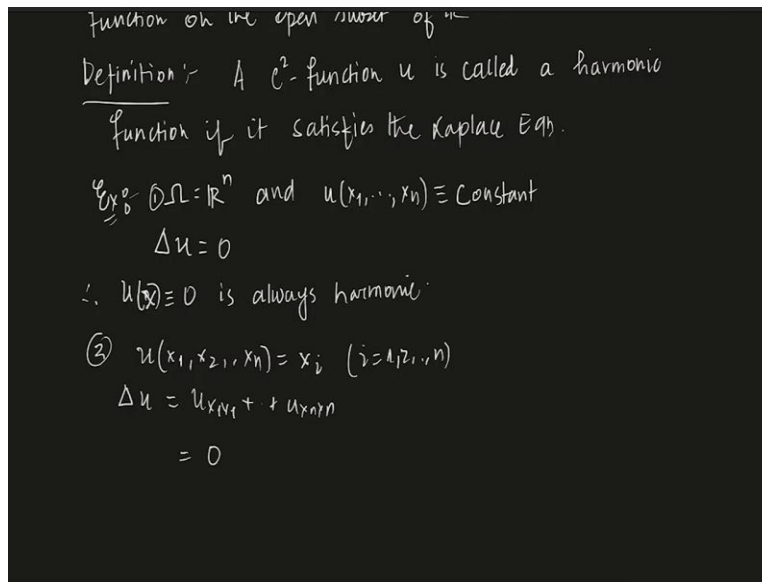

You can write it as xy also, but in that case, you cannot, I mean, I just want to I mean, reserve x for a element in \mathbb{R}^n . So x is $x_1 x_2$, so essentially, when I am saying it is a element of \mathbb{R}^n , what I meant is, so let me put it here to the \mathbb{R}^n . So this is u_{xx} , n equal to 2 is just this I mean, here I just want to write x is in ω subset of \mathbb{R}^n means x , so essentially x is $x_1 x_2 \dots x_n$. I mean, you do not have to worry about x_n , the end component just two component, whatever, it does end component same sort of thing.

(Refer Slide Time: 14:59)

Laplace Equation:- $\nabla u = (u_{x_1}, u_{x_2})$
 $\Delta u = \text{div}(\nabla u) = u_{x_1 x_1} + u_{x_2 x_2} + \dots + u_{x_n x_n} = 0$ $\text{div}(\nabla u) = u_{xx} + u_{yy}$
Poisson Equation:- (x_1, x_2)
 $-\Delta u = f$
Here, $x \in \Omega (\subseteq \mathbb{R}^n)$ ($x = (x_1, x_2, \dots, x_n)$)
 $u: \bar{\Omega} \rightarrow \mathbb{R}$ is unknown function and f is any given function on the open subset of \mathbb{R}^n .

Now, Poisson equation is minus Laplacian of u equals to f , this f will be given to you, u from $\bar{\Omega}$ to \mathbb{R} is the unknown function which you need to find unknown function. And f is any given function on the open subset of \mathbb{R}^n , so, just think about it what I am saying, what I have said is you are looking at u which is from $\bar{\Omega}$, $\bar{\Omega}$ is a closed set. As I told you, if I am not specifying what exactly Ω is most of, all the time in this course, just assume Ω to be an open set in \mathbb{R}^n . So, $\bar{\Omega}$ is a closed set the closure of Ω to \mathbb{R} that is an unknown function and f is any given function on a open subset of \mathbb{R}^n . Now the question is you just have to find what u is that is the question.

(Refer Slide Time: 16:15)

So, we start with a small definition here, definition. So, let us say C^2 function u is called a harmonic function if it satisfies the Laplace Equation. So, if we are looking at a u such that Laplacian of u equals to 0 then that is, that sort of function is called a harmonic function. Now, example, take 5 seconds, just think about an example of a harmonic function. Let me tell you what is very easy example, let us say if your, let us say Ω to be \mathbb{R}^n and u of $x_1 \times \dots \times x_n$ to be identically equals to a constant.

Now, if that is the case, what do you think Laplacian of u should be any derivative of this is 0. So, Laplacian equals to 0. So that is a trivial harmonic function. And, of course, one special thing about harmonic functions are 0 is always included. So 0, so $u(x)$ equals to since constants always hold 0, therefore $u(x)$ equals to 0 is always harmonic. And this is harmonic in any domain. I mean, it does not matter whenever you can take any Ω you want Ω is any open set, and u of x is always going to be a harmonic function. So that is one example.

Can you give think of another example? So let us assume that Ω is an open set, and u of x_1 maybe, I do not know, maybe x_1, x_2, \dots, x_n let us just call it I am writing it for x_n you can just think of two dimension also no issues. So let us say that is x_i , whatever i is, i can be 1, 2, whatever, n . Now if that is the case, let us look at what Laplacian of u is, Laplacian of u in this case is $u_{x_1 x_1} + \dots + u_{x_n x_n}$. Now I do not have to calculate this thing, you guys can understand that this is

going to be 0. So any coordinate function, this sort of function is called a coordinate function. Any coordinate function is harmonic.

(Refer Slide Time: 19:19)

$$\begin{aligned}
 &= 0 \\
 \textcircled{3} \quad u(x_1, x_2) &= x_1^2 - x_2^2 \\
 \Delta u &= u_{x_1 x_1} + u_{x_2 x_2} \\
 &= 2 + (-2) = 0
 \end{aligned}$$

Properties:

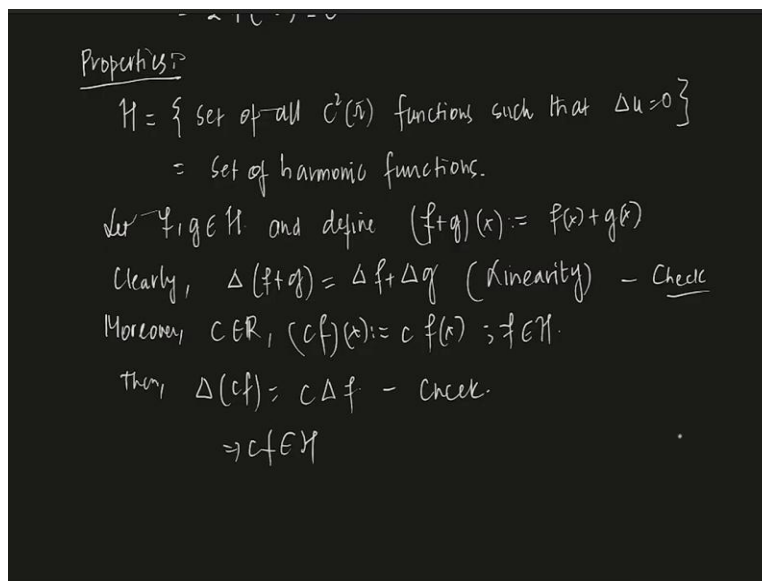

$$\mathcal{H} = \left\{ \text{set of all } C^2(\bar{\Omega}) \text{ functions such that } \Delta u = 0 \right\}$$

= set of harmonic functions.

Let us take another non-trivial function here. So in two dimension, let us just think two dimension x_1, x_2 , to be x_1 square minus x_2 square. Let us see if this is harmonic or not. It may be, it may not be, let us just look at it. Laplacian of u is U_{xx} , $x_1 x_1$ minus $U_{y_1 y_1}$ plus U_{y_1} . Now, $U_{x_1 x_1}$ as you can see, the first derivative is $2x_1$ second derivative is x_2 . So that is $2x_1$ sorry this is not y_1 along, it is $x_2 x_2$ plus $2x_2 x_2$ is minus 2 that will give you 0. So Laplacian of u is 0. So, hence, this is an example therefore $U_{x_1 x_2}$ given by x_1 square minus x_2 square is also harmonic.

So, I mean there are going to be other examples also, but these are more or less the basic examples of harmonic function. Before we move on let us look at what is so special about harmonic function. So, first of all properties, we define \mathcal{H} to be the set of all C^2 omega bar functions such that Laplacian of u equals to 0. So, this is the set of harmonic functions, set of harmonic functions. \mathcal{H} is a set of all C^2 omega bar functions such that Laplacian u equals 0. So, that is a set of harmonic function.

(Refer Slide Time: 21:20)

Now, I want to see what are some special properties of this set. Let us say that let f and g are in H , let us see what happen and define f plus g acting at x to be f of x plus g of x . If I define it like this clearly see if this is the case then Laplacian of f plus g , this is going to be Laplacian of f plus Laplacian of g , how is this true because of linearity. If you are not convinced about this thing, I am not proving all of this here, it is going to be time consuming I mean, it is not, it is just two lines, but please check this part here it is not very difficult.

Moreover, you see for a c in \mathbb{R} , if you define c times f acting at x to be c times f of x and f is in H , you start with a f in H and c in \mathbb{R} and you define cf like this, then Laplacian of cf let us see what happens, it is definitely c times Laplacian of f this also you can check, please check this part, check this.

Now, think about this. If you consider this property that given two functions f and g the sum is linear and constant times f is also in H . So, this definitely belongs to H , it means that cf belongs to H . What does that say, it says therefore H is a vector space, H is a vector space. So, this is very special about H . All of this happening because the operator is a linear operator. Since delta, so this is called a delta, this symbol is called delta is a linear operator. Now, what we are going to do is we are going to look at some physical interpretations how, where do we use this sort of operator.

(Refer Slide Time: 23:55)

Moreover, $c \in \mathbb{R}$, $(cf)(x) := c f(x) ; f \in H$.
Then $\Delta(cf) = c\Delta f - c\Delta c$.
 $\Rightarrow cf \in H$
 $\therefore H$ is a vector space ($\because \Delta$ is a linear operator).
Physical Interpretation
 $u =$ density of some chemical composition in equilibrium.
 $\Omega =$ Region where the chemical is contained.

See this is the most widely used operator in all of partial differential equation and probably one of the most important objects in all of mathematics Laplacian. So, it is very important that we know understand and I mean appreciate what, how beautiful this operator is. So, let us look at some physical interpretation. So, first of all, let us assume that u is the density of some chemical concentration in equilibrium.

Let us assume u is some function, so this represents the density of some chemical composition. I mean some substance is given you are looking at a chemical composition of that thing in equilibrium, equilibrium means when it is stable. Now, let us say that the chemical is contained in some I mean region which we will call as ω .

So, the region where the chemical is contained. So, that is your ω , ω is our domain. So, let us see what happen. See, let us say that is your ω . Now, let us assume that v is some. So, let v be a smooth region contained in ω . So, that is your v let us say any smooth region which is contained in ω . If that is the case, there seems to be some problem with the software.

(Refer Slide Time: 26:28)

$v \in \Omega$ is smooth

\therefore the net flux of u through ∂v is zero.

$$\int_{\partial v} F \cdot \nu \, ds = 0$$

where F is the flux density and ν is the unit outward direction.

From Gauss divergence theorem

\therefore the net flux of u through ∂v is zero.

$$\int_{\partial v} F \cdot \nu \, ds = 0$$

where F is the flux density and ν is the unit outward direction.

From Gauss divergence theorem,

$$\int_v \operatorname{div} F \, dx = \int_{\partial v} F \cdot \nu \, ds = 0$$

$\Rightarrow \operatorname{div} F = 0$ in Ω (v is arbitrary)

Check
 $u \in C^2(\Omega)$ be
 such that
 $\int_v u \, dx = 0$
 for any smooth $v \subset \Omega$
 then $u \equiv 0$ in Ω

Let us just take another page. So, if that is the case then, so basically what I am saying is if v is a smooth so containing u smooth, is smooth. So, what am I doing that is your u and this is where the chemical, so the chemical is and u is the density of the chemical and that chemical is in equilibrium and you are just looking at another small sub-region, which is v , sorry this is not u only is in Ω . v something in Ω .

Now, since the I mean the chemical, the concentration that is in equilibrium, the chemical is in equilibrium. So, therefore, the net flux, so net flux means whatever is going in or coming out of u through the boundary of v , $\operatorname{div} v$ is 0, this is quite easy. And if that is proved what does that say

$\text{div } \mathbf{F}$ if $\int_V \mathbf{F} \cdot d\boldsymbol{\gamma}$ is 0. So, basically there is no flow of, the flux density is not changing in the unit direction. So, let us say $\boldsymbol{\gamma}$ is this, $\boldsymbol{\gamma}$ is the unit outward direction. So, where \mathbf{F} is the flux density and $\boldsymbol{\gamma}$ is the unit outward direction.

So, what I meant by this is, see the whole liquid or whatever the chemical is it is in equilibrium. So, if you look at a small region wherever on the Ω , small smooth region the net flow of the chemical, the density, the change in the density basically the net flux of \mathbf{u} , through this boundary of the V that is going to be 0. So, if \mathbf{F} denote the flux density then I mean in that direction in any direction I mean whatever the $\boldsymbol{\gamma}$ is here, in any given direction $\boldsymbol{\gamma}$, the flux density if you take the integral of that that is going to be 0.

Now, if that is the case from Gauss theorem actually, from Gauss divergence if you remember when you looked at I mean integration by parts, I said that it is going to be one of the most important how do I put it most things important thing you can learn integration by parts. We are going to use that integration by parts over here.

So, let us say that $\int_V \text{div } \mathbf{F} \, dV = 0$, then use Gauss divergence and say that you see $\int_V \text{div } \mathbf{F} \, dV = \int_{\partial V} \mathbf{F} \cdot d\boldsymbol{\gamma}$ that is equals to $\int_V \text{div } \mathbf{F} \, dV$ and that is going to be 0, yes. So, how are you getting, this is Gauss divergence theorem. So, basically GD Gauss divergence theorem, Gauss divergence theorem says this and from here we get this flux is 0.

Now see this V is arbitrary, this V can be anything. So, you are saying that a object when you integrate that object over any sub-regions, move sub-region that is going to be 0, what does that say that the divergence of \mathbf{F} is going to be 0 in V , V is arbitrary of course, in Ω , arbitrary, in Ω , I have to say it is in Ω . Why it is in Ω , see V is contained in Ω , V is arbitrary. So, you are saying that you are taking the divergence, you are taking some object and integrating it in any smooth sub-region of Ω and that integration is 0, so definitely the object in question that is going to be 0.

If you are not convinced here please check this part. So, check this, check that let us say u is in C^2 let us say $u \in C^2(\Omega)$ be such that $\int_{\partial V} u \, ds = 0$ for any smooth V containing Ω , then u has to be 0 in Ω . See one thing is this why am I talking about smooth V in Ω . If you remember Gauss divergence theorem says that you have to have

this region where you are integrating, that region has to be a smooth region at least C^1 . So that is why I am just assuming it to be smooth.

(Refer Slide Time: 32:04)

Fick's Law of diffusion
 $F = -c \nabla u$ (Flow is from the region of higher to lower concentration)
(c>0)
 $\therefore \operatorname{div}(-c \nabla u) = -c \operatorname{div}(\nabla u) = 0$
 $\Rightarrow \Delta u = 0$ (c>0)
Laplace Equation

Now, you see there is something called, since we are talking about chemical concentration, there is something called a Fick's Law of diffusion this is from your physics, Fick's Law of diffusion that says that the flux density F is proportional to the gradient of u . So, basically what it is saying is minus some constant times gradient of u . So, why minus because the flow, the flux density the flow, is from the region of higher to lower concentration.

See, if there is a flow in the system here it is none, if there is a flow in the system that is always going to be from a region of higher concentration to the lower concentration. So, that is why this negative sign is there, you just say that the flow is somehow in a negative way. And this C , of course, is a constant or proportionality, I mean, we are just saying that it is proportional to gradient of u , and gradient of u is just the change of the flux. So, basically it is the change in the density.

And this C is positive we are assuming because otherwise there is minus C we will get it. So, if f is minus C times gradient u , let us just put it here therefore divergence of minus C times gradient of u that will give you minus C times divergence of gradient of u that will be 0, because divergence of f is 0, f look like this. So, divergence of gradient u is 0. So, that will give us that

Laplacian of u is 0 because C is positive. Since C is positive, that will give you our minus Laplacian, I do not care.

Now, see, the very important thing is this is from Fick's Law, we got that Laplacian of u is equals to 0 now you just if you want to, so this is the Laplace Equation, that is the Laplace Equation. The whole idea of this is see here, if it is chemical concentration, you are talking about Fick's Law. Fick's Law will give us the Laplace Equation. Actually, if it is a Fourier law of heat conduction that is also similar to this, if the Fourier law of heat conduction, then that also will give you a Laplace Equation.

In that case, u will consider so let us say for heat conduction, u will be your temperature, the function u . And if it is a Ohm's Law, electricity conduction then u will be the electrostatic potential. So this is a very, very important thing to understand. So with this what we are going to do is in the next lecture set of lectures, we are going to talk about how to work with Laplace Equation, yeah. So with this we are going to end this particular video.
