Vector Spaces, Subspaces, linearly Dependent/Independent of Vectors

Now we are ready to define a vector space or a linear space or which is the basic object of a linear algebra.

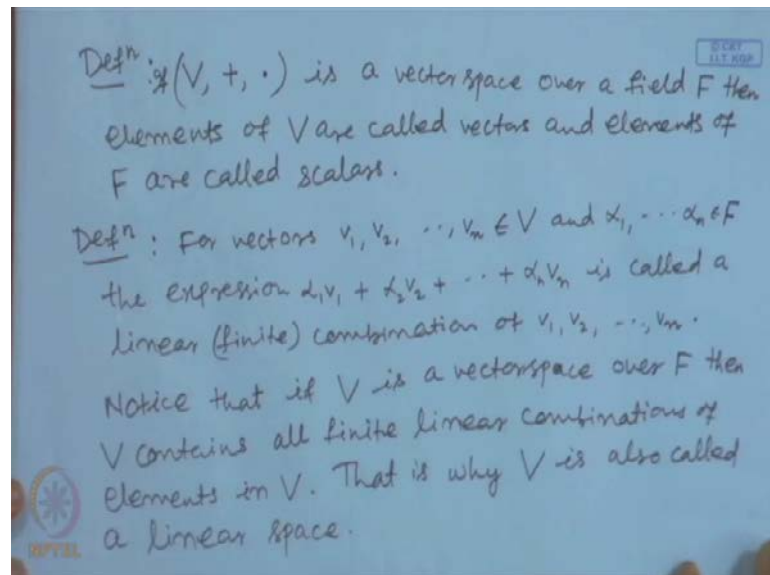

(Refer Slide Time: 00:37)

So, we will say these vector spaces. So, this is also starts with a non-empty set with some operations. A non-empty set given together with operations called addition and scalar multiplication **scalar multiplication** is a vector space over a field F , if the following axioms hold: first one is this; V with respect to this addition operation is a commutative group. Second property is that, V is closed under scalar multiplication; that is, for any element u in V and α belongs to F , this $\alpha \cdot u$ belongs to V . Third property is this, for α, β in F and u belongs to V , $\alpha + \beta$ dot u is equal to α dot u plus β dot u . Fourth property is for α belongs to F , and elements u and w in V , α dot u plus w is equal to α dot u plus α dot w . Fifth property is that, for α, β in F , and u in V , α dot β dot u is equal to $(\alpha \beta)$ dot u .

beta u. And this sixth axiom is this, $1 \cdot u$ is equal to u , for every element u in V , and 1 is the multiplicative identity of F , identity of this field. So, if a non empty set together with two operations called addition and scalar multiplication, that is called a vector space over a field F if this axioms hold.

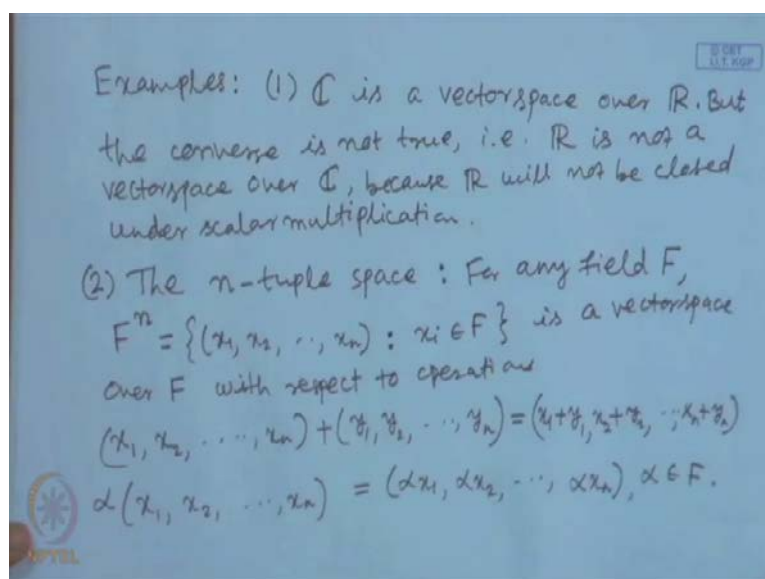

(Refer Slide Time: 05:24)

Here, whenever this V together with addition and scalar multiplication is a vector space. So, if this is a vector space over a field F then, elements of v are called **elements of V are called vectors**, and elements of F are called **elements of F are called** scalars.

So, we will have also linear combination of vectors that, for vectors v_1, v_2, v_n in V and α_1, α_2 to α_n in F . The expression $\alpha_1 v_1$, plus $\alpha_2 v_2$ plus $\alpha_n v_n$ is called a linear. Of course, this is also made this set as finite linear combination of v_1, v_2 to v_n . Notice that, if V is a vector space over F then, V contains all finite linear combinations **all finite linear combinations** of elements in V . That is why V is called a linear space. **that is why v is also called a linear space**

(Refer Slide Time: 08:48)

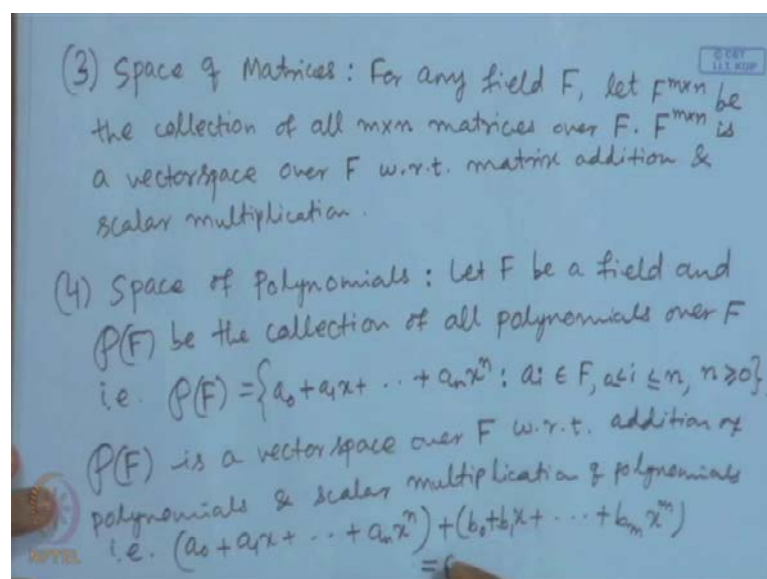

Next, we will have some example of vector spaces. So, the first example that is very natural one is that, set of complex numbers \mathbb{C} is a vector space over the real field \mathbb{R} , but the converse is not true, **but the converse is not true** that is \mathbb{R} is not a vector space over \mathbb{C} , because \mathbb{R} will not be closed under scalar multiplication.

So, the second example is basically, that is called the n -tuple space **the n tuple space** that is, for any field F , **for any field** F to the power n that is Cartesian product of F with itself, n number of times that, F to the power n consist of all n tuple that x_1, x_2 up to x_n such that, each x_i is an element of F . This is the F to the power n is a vector space over F with respect to the operations. That for any two elements that addition is defined like this: x_1, x_2 to x_n plus y_1, y_2 to y_n is equal to x_1 plus y_1, x_2 plus y_2 , like this x_n plus y_n coordinate wise addition. And scalar multiplication is α times this x_1, x_2, x_n that is equal to $\alpha x_1, \alpha x_2, \alpha x_n$ for any α in F .

So, here we can observe that, this \mathbb{R} to the power n is also vector space because. So, as a particular case **as a particular case as a particular case** \mathbb{R} to the power n is a vector space over \mathbb{R} , this \mathbb{R} to the power n is also called that n dimensionally Euclidean space.

(Refer Slide Time: 12:58)

Next, we will have this example, third example that is, space of matrices: space of matrices, that collections of some matrices also form vector space. So, here for any field F , let us denote that F to the power m into n be the collection of all m into n matrices over F . Then this F to the power m into n this is a vector space over this field F with respect to matrix addition and scalar multiplication. with respect to matrix addition and scalar multiplication

So, next we will have this fourth example, it is space of polynomials: space of polynomials. So, let F be a field and $P(F)$ be the collection of all polynomials over F that is, $P(F)$ is this set of all polynomials a_0 , plus a_1x , plus a_nx to the power n , such that each a_i that comes from this field F , i from greater than or equal to 0 , less than or equal to n , and this n is an integer that is greater than or equal to 0 . So this, $P(F)$ will be the collection of all this polynomial. So, over this field F is a vector space, over this field F with respect to addition of polynomial and scalar multiplication of polynomials with respect to addition of polynomials and scalar multiplication of polynomials that is, you were having two polynomials that a_0 , plus a_1x , plus a_nx to the power n plus another polynomial say b_0 , b_1x , plus b_mx to the power m then, their sum is the polynomial c_0 , plus c_1x up to this c_kx to the power k .

(Refer Slide Time: 17:42)

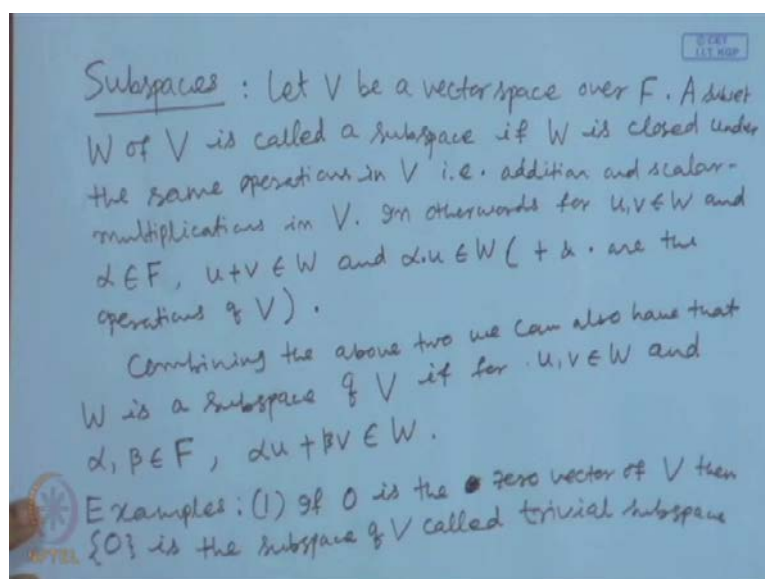

$c_i = a_i + b_i, 0 \leq i \leq k, k = \max\{n, m\},$
 $a_i = 0 \text{ for } i > n, b_i = 0 \text{ for } i > m.$
 For $\alpha \in F, \alpha(a_0 + a_1x + \dots + a_nx^n) = \alpha a_0 + \alpha a_1x + \dots + \alpha a_nx^n$

Lemma: If V is a vector space over F then
 (a) $\alpha \cdot 0 = 0, \alpha \in F$ and 0 is the additive identity of $(V, +)$ called the zero vector.
 (b) $0 \cdot v = 0, v \in V$, and 0 in LHS is the scalar zero & 0 in RHS is the vector zero.
 (c) $(-\alpha) \cdot v = -(\alpha v)$, for $\alpha \in F, v \in V$.
 (d) If $v \neq 0$ in V then $\alpha \cdot v = 0$ implies that $\alpha = 0$

Where this k is equal to for this c_i is your c_i is equal to $a_i + b_i$, for i greater than or equal to naught, less than or equal to k and k is equal to maximum of $\{n, m\}$ and of course, this a_i is equal to naught for i greater than n , and b_i is equal to naught for i greater than m . And for any scalar α , in to any polynomial that a naught, plus a_1x , plus a_nx to the power n is equal to αa naught, plus αa_1x like this αa_nx to the power n . So then, we can have some natural properties of a vector space that we will write in a lemma and then of course, the proof of this lemma is not difficult to check and one can take this is an exercise.

So, these properties are very trivial, but useful we use them again and again. So, if V is a vector space over a field F then, we will have the following results. A is this: α dot naught is equal to naught, for α belongs to F and naught is the additive identity of $(V, +)$ called the naught vector. Second property we can have is this, 0 dot any vector v that is equal to naught, for any vector v in the vector space, and naught in LHS is the scalar naught and naught in RHS is the vector naught. Third property we can having this, minus α into v is equal to minus αv , for any α in the field F , and that v in the vector space. Fourth property you can having this, if v is not equal to non naught vector not equal to naught or a non naught vector in v , then α dot v is equal to naught implies that α equal to naught; that means, for any non naught vector v if this α dot v , v equal to naught then α equal to naught for any α in F .

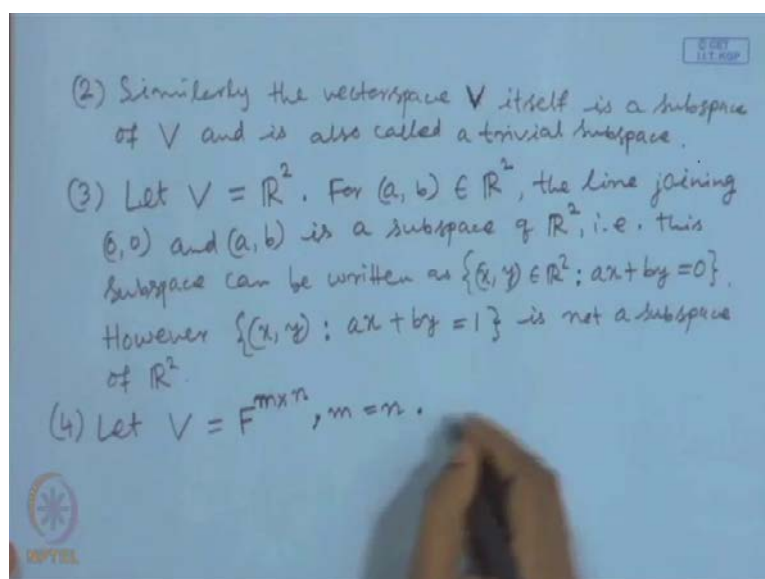

(Refer Slide Time: 23:03)

So, the next we will write this subspaces concept, whenever we are having some algebraic structure we have it is sub structure. So, we will have these subspaces. So, let V be a vector space over a field F . Then a subset **a subset** W of V is called a subspace. If W is closed under the same operations **same operations** in V that is, addition and scalar multiplications **scalar multiplications** in V . In other words **in other words** for u, v belongs to W and α belongs to F , u plus v belongs to W and this αu belongs to W (**plus, and this dot** plus, and, dot are the operations of V). Operations of V ; One can also combine this two and write in a single condition that combining the above two we can also have that W is a sub space of V if for u, v belongs to W and α, β belongs to F , αu plus βv belong to W .

So, let us see some example of subspaces, **let us set some example of sub spaces sub**. So, that trivial subspaces are if this naught is the naught vector of **is the naught vector of** V then, this set consist of the naught vector only is the **this is a sub space this is the** sub space of V **called trivial** called trivial subspace.

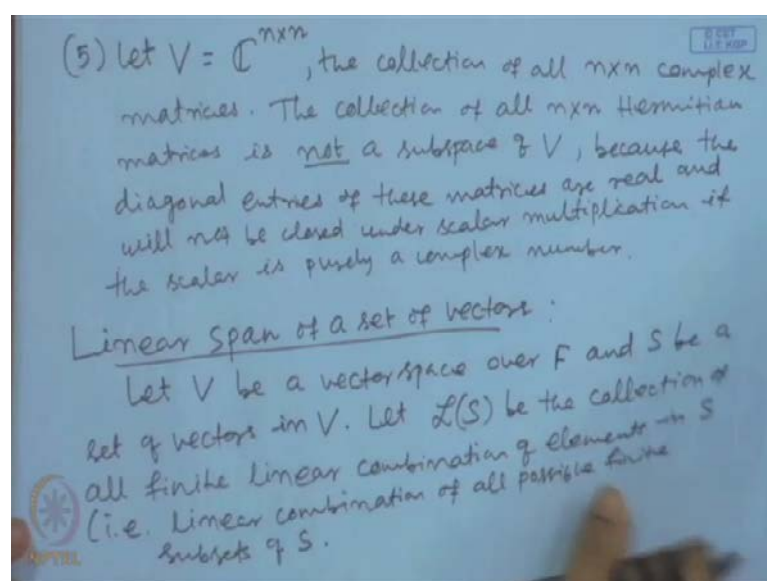

(Refer Slide Time: 27:38)

Similarly **similarly** the vector space V **the vector space V** itself is a subspace **subspace** of V and is also called a trivial subspace. So, next will have another example, let us consider this \mathbb{R} to the power 2, we will take this Euclidean plane \mathbb{R} to the power 2 then, this for any point (a, b) in \mathbb{R} to the power 2, the line joining the origin $(0, 0)$ and this point (a, b) is a subspace of \mathbb{R} to the power 2, that is; this subspace can be written in set of all (x, y) in \mathbb{R} to the power 2 such that $a x$ plus $b y$ is equal to naught; however, if we consider any other line that is not **not** passing through the origin; however, this line that collection of all (x, y) such that $a x$ plus $b y$ is equal to one, this is not passing through origin is not in subspace of \mathbb{R} to the power 2.

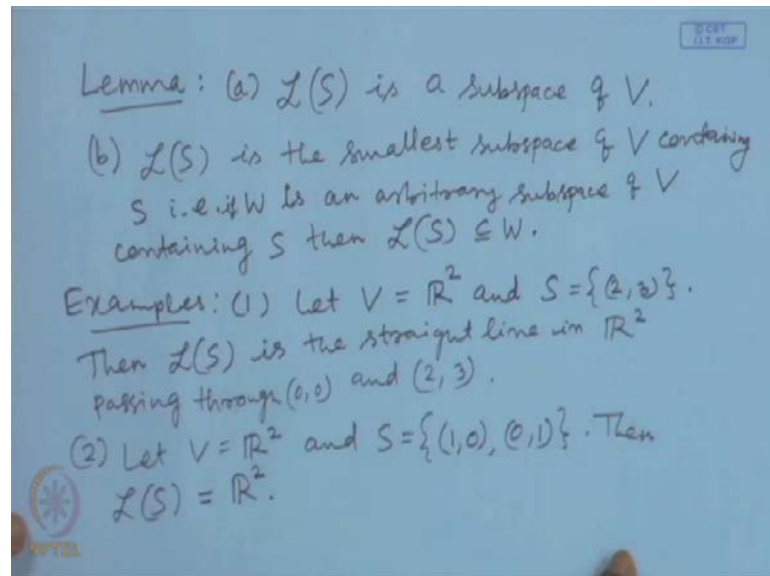

So, next we will have different kind of vector space and sub spaces, **that is** they are matrices. So, now you consider this set of all m by n . Let V be the space of this n -tuple no **we will** **sorry**. We will consider this V with this set of all m into n matrices over F , then the collection of all with this m into n matrices with m is equal to n then, this set of all m into n symmetric matrices over F form a subspace of V . **then the collection of all n by n symmetric matrices over F forms a sub space of this V .**

(Refer Slide Time: 32:17)

Similarly we will write another example that, fifth example, that the set of all hermitical matrices. Let, again we will consider this vector space V be \mathbb{C} to the power m into n or in other words, the collection of all n into n complex matrices. This is the collection of all n into n complex matrices. Then here the collection of all n into n hermitian matrices **hermitian matrices** is not a subspace **not a subspace** of V , because the diagonal entries of this matrices are real and we will not be closed under scalar multiplication **scalar multiplication**, if this scalar is purely a complex number a complex number. So, these are some example of subspaces then **we will** we will define another important concept that is a linear span of a set. Linear span of a set of vectors. So, let us have a vector space let V be a vector space over field F and s be a set of vectors in V . So, let us denote, let $L(s)$ be the collection of **collection of** all **finite linear combination of** finite linear combination of elements in S . Finite linear combination means; linear combination of finite number of elements in S that is, linear combination of **linear combination of** all possible finite subsets of S then, this $L(s)$ satisfy some properties that we will write that as a lemma of course.

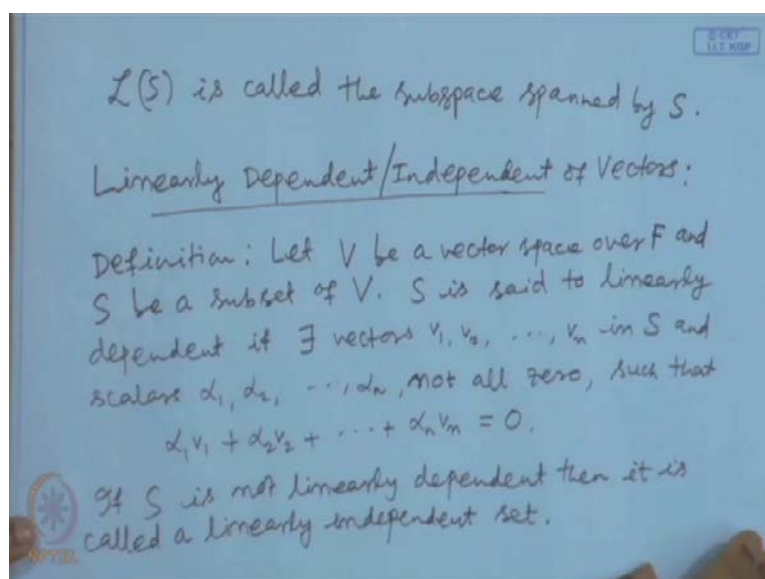

(Refer Slide Time: 36:46)

This proof is easy and that is, then let us and exercise it is not difficult to check, that first **first** property is this $L(S)$ is a sub space **$L(S)$ is a sub space** of V . And second, that one can see is that. In fact, not only this is subspace, this $L(S)$ is the smallest subspace **smallest sub space** of V containing **containing** S . $L(S)$ is the smallest sub space of V containing S , in other words that is another the W is, that is if W is an arbitrary subspace of V containing S then, this $L(S)$ will be contained in W . This you mean that, this $L(S)$ is the smallest subspace. It will be contained in a subspace if that subspace contains this set S . So, let us have some examples.

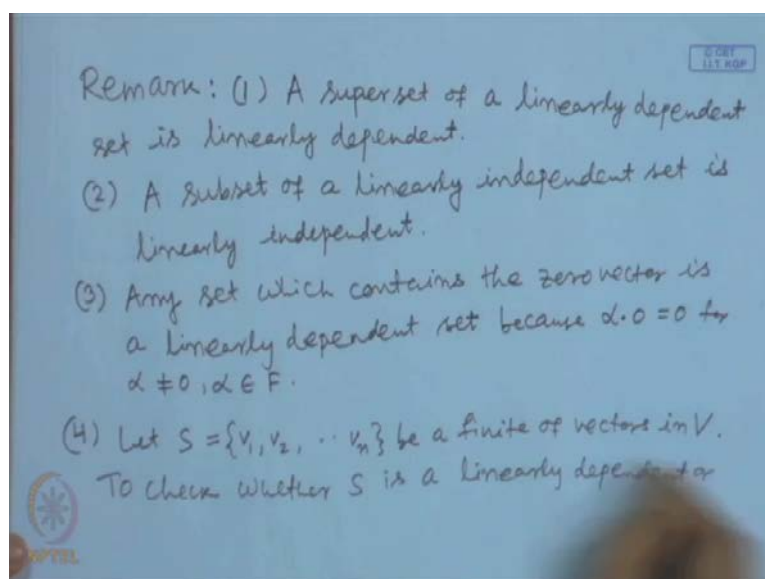

So, first example is that, we can take this vector space is equal to \mathbb{R} to the power 2 and this S is consist of only one element **1 element** or 1 vector of this vector space, that is $(2, 3)$ then $L(S)$ is actually the straight line passing through origin and $(2, 3)$, then $L(S)$ is the straight line in \mathbb{R} to the power 2 passing through the origin $(0, 0)$ and $(2, 3)$. This point, second **second** example is that, again if you take this V is equal to \mathbb{R} to the power 2 and S is consist of the points $(1, 0)$ $(0, 1)$ then $L(S)$ is equal to the whole space \mathbb{R} to the power 2.

(Refer Slide Time: 40:43)

So, this linear span of sets will be useful and this $L(S)$ is also called this subspace spanned by S . $L(S)$ is called the sub space spanned by the set of vectors S . Then we will discuss about linearly dependent and independent of vectors. So, that is very important concept in a linear algebra, linearly dependent or independent of vectors. So, this is the very important concept in linear algebra. So, give this definition. So, let V be a vector space over a field F and S be a subset of V . **subset of V** . S is said to be a linearly dependent **said to be linearly dependent** if there exist **there exist** vectors v_1, v_2 to v_n in S and scalars α_1, α_2 to α_n not all naught of course, α_n not all naught, this is very important such that, this linear combination $\alpha_1 v_1$, plus $\alpha_2 v_2$, plus $\alpha_n v_n$ is equal to naught. This naught is the naught vector. If S is not linearly dependent **not linearly dependent** then it is called a linearly independent set. **linearly independent set**.

(Refer Slide Time: 44:22)

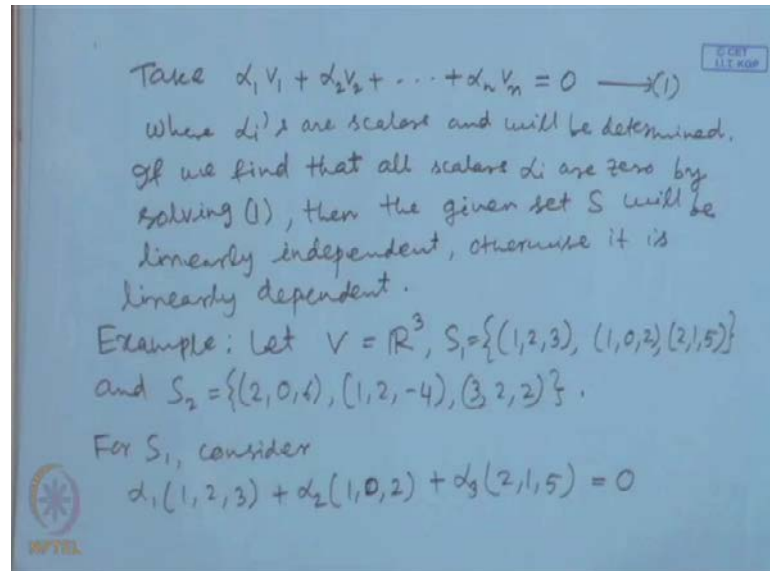

Here we will have some results in this linearly dependent and independent sets they are trivial. So, we can write them as a remark set of things of course, these are trivial, and trivially one can get using the definition of linearly dependent and independent of vectors. So, first one is like this; a super set **a super set** of a linearly dependent set **of a linearly dependent set** is linearly dependent. Similarly you can have, that a subset every subset of a linearly independent **linearly independent** set is linearly independent. And third observation one can have is this, any set which contains the zero vector **which contains the 0 vector** is a linearly dependent set **linearly dependent set** because $\alpha \cdot 0 = 0$ for $\alpha \neq 0, \alpha \in F$.

Then fourth remark we can have that, here one can check this and a linearly dependency of a finite number of vectors suppose, a finite number of vectors are given and we want to check whether they are linearly dependent or independent. So, how should we do? What is the working formula for that? So, this is all about the definition that we have given, but how to check? And what is the method for checking either a given of course, finite set of vectors are linearly dependent or independent? So, using this definition also one can check directly and we will also give another method for verification of linearly dependent and independent by using some special type of matrices. So, here we consider that, I mean let that S be subset of vectors that v_1, v_2 to v_n be a finite set of vectors in V . So, to check whether S is **whether s** is a linearly dependent or independent set

independent set we do the following that is, we consider a linear combination of vectors in S and equal to zero.

(Refer Slide Time: 48:55)

Take this $\alpha_1 v_1 + \alpha_2 v_2 + \dots + \alpha_n v_n = 0$. Where α_i 's are scalars and will be determined. So, if we can find that **if we find that** all scalars α_i 's are 0, scalars α_i are 0, **say this equation 1** by solving equation one, then **then** the given set S will be linearly independent, otherwise it is linearly dependent. So, let us take one example and explain this concept. That you take a V be \mathbb{R}^3 and S_1 be the set of vectors $(1, 2, 3)$ $(1, 0, 2)$ $(2, 1, 5)$ and S_2 be the set of vectors $(2, 0, 6)$ $(1, 2, -4)$ $(3, 2, 2)$ **subset** subsets of V . So, we will check linearly dependency or independency of S . So, for S_1 consider this $\alpha_1(1, 2, 3) + \alpha_2(1, 0, 2) + \alpha_3(2, 1, 5) = 0$ take this linear combination of vectors in S_1 and equal to naught.

(Refer Slide Time: 52:28)

Then we get equations

$$\alpha_1 + \alpha_2 + 2\alpha_3 = 0$$
$$2\alpha_1 + \alpha_3 = 0$$
$$3\alpha_1 + 2\alpha_2 + 5\alpha_3 = 0$$

On solving these equations we get $\alpha_1 = \alpha_2 = \alpha_3 = 0$.

So S_1 is a linearly independent set.

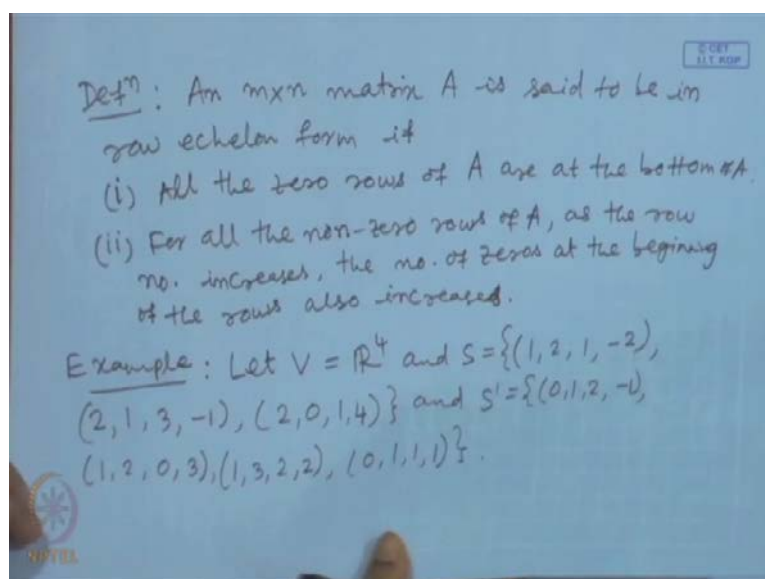

For S_2 , we can take $\alpha_1 = \alpha_2 = 1$ and $\alpha_3 = -1$ & get $\alpha_1(2, 0, 6) + \alpha_2(1, 2, -4) + \alpha_3(3, 2, 2) = 0$.

So S_2 is a linearly dependent set.

Then we will get equations like this, then we get equations alpha 1 plus alpha 2 plus 2 alphas 3 is equal to 0. Two alpha 1 plus alpha 3 is equal to 0. 3 alphas 1 plus 2 alpha 2 plus 5 alpha 3 is equal to 0.

On solving these **system on solving this** equations **these equations** we get alpha 1, alpha 2 and alpha 3 are all equal to 0. Therefore, this S_1 is a linearly independent set; however, for S_2 . So, S_2 we can take alpha 1 is equal to alpha 2 equal to one and alpha 3 equal to minus 1 and get that, this alpha 1 times (2, 0, 6) plus alpha 2 times (1, 2, minus 4) plus alpha 3 times (3, 2, 2) is equal to 0. So, S_2 is a linearly dependent set. **this is a linearly dependent set.** So, there is another way also to verify that whether the given set of vectors are linearly dependent or independent and for that we need a type of matrix it is called echelon matrix.

(Refer Slide Time: 54:55)

So, here we give this definition of an echelon matrix. So, an m into n matrix A is said to be in **echelon form** if it satisfies the following. That first condition is that all the 0 rows of A are at the bottom of A . And second is this, for **the entire non zero rows** all the non-zero rows of A , as the row number increases, the number of 0's at the beginning **at the beginning** of **at the beginning of** the rows also increases **also increases**. So, let us see one example here, how to apply this echelon matrices and verify whether it is a set of vectors are linearly dependent or independent. So, let us take V be the vector space \mathbb{R} to the power 4 and S be the set of vectors that $(1, 2, 1, \text{minus } 2)$, and this $(2, 1, 3, \text{minus } 1)$, $(2, 0, 1, 4)$ and S' be the set of vectors $(0, 1, 2, \text{minus } 1)$, $(1, 2, 0, 3)$, $(1, 3, 2, 2)$, $(0, 1, 1, 1)$. So, let us verify whether they are linearly dependent or independent sets. So, for this set S , this subset S of vectors we form a matrix by taking the vectors in S , S rows.

(Refer Slide Time: 58:32)

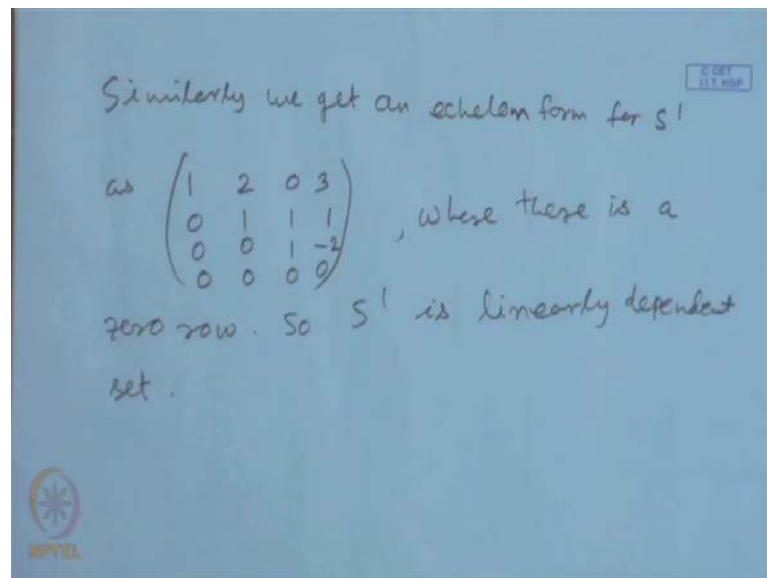

from S form matrix

$$\begin{pmatrix} 1 & 2 & 1 & -2 \\ 2 & 1 & 3 & -1 \\ 2 & 0 & 1 & 4 \end{pmatrix} \xrightarrow{R_2 \rightarrow R_2 - 2R_1} \begin{pmatrix} 1 & 2 & 1 & -2 \\ 0 & -3 & 1 & 3 \\ 2 & 0 & 1 & 4 \end{pmatrix} \xrightarrow{R_3 \rightarrow R_3 - 2R_1} \begin{pmatrix} 1 & 2 & 1 & -2 \\ 0 & -3 & 1 & 3 \\ 0 & -2 & -1 & 8 \end{pmatrix} \xrightarrow{R_3 \rightarrow 3R_3 - 2R_2} \begin{pmatrix} 1 & 2 & 1 & -2 \\ 0 & -3 & 1 & 3 \\ 0 & 0 & -5 & 18 \end{pmatrix}$$

The last matrix is in echelon form. Here there is no non-zero row. So S is a linearly independent set.

So, from S form matrix, that (1, 2, 1, minus 2) taking the vector says rows of this matrix, and the (2, 0, 1, 4). So, applying this elementary row operations or replacing R 2 by R 2 minus twice R 1, we get this matrix that (1, 2, 1, minus 2) this is unchanged and (0, minus 3, 1, 3) (2, 0, 1, 4). So, again from this matrix we can have this elementary row operation R 3, that we replace R 3 by R 3 minus twice R 1 and get this matrix (1, 2, 1, minus 2) (0, minus 3, 1, 3) (0, minus 2, minus 1, 8) and again by elementary row operations, that R 3 we replace by this 3 R 3 minus twice R 2 and we get this matrix that (1, 2, 1, minus 2) (0, minus 3, 1, 3) (0, 0, minus 5, 18) the last matrix **matrix** is in echelon form. Here there is no non-zero **zero** **there is no non zero** row. So, S is a linearly independent set linearly independent set.

(Refer Slide Time: 1:01)

Similarly, one can get this echelon form of S prime like this. Similarly, we get an echelon **echelon** form for S prime as this $(1, 2, 0, 3) (0, 1, 1, 1) (0, 0, 1, \text{minus } 2) (0, 0, 0, 0)$ where there is a zero row. So, S prime is linearly dependent **linearly dependent** set. This is how we verify that whether set of vectors are linearly dependent or independent by using this echelon form of matrices, that given any **set of** finite set of vectors we form a matrix by taking the rows of the matrix is the vectors in that set and we convert to echelon form. If in the echelon form all the rows are non zero then, this set will be linearly independent. And if there is a zero row then these set of vectors will be linearly dependent set of course, we will repeat this echelon form again in our next lecture while finding basis, and dimension of vector spaces that is all for this lecture. **thank you.**
