Lecture No. # 06
Method to Find Eigenvalues and Eigenvectors
Diagonalization of Matrices

So, here we will discuss about a method to find eigenvalues and eigenvectors of matrices.

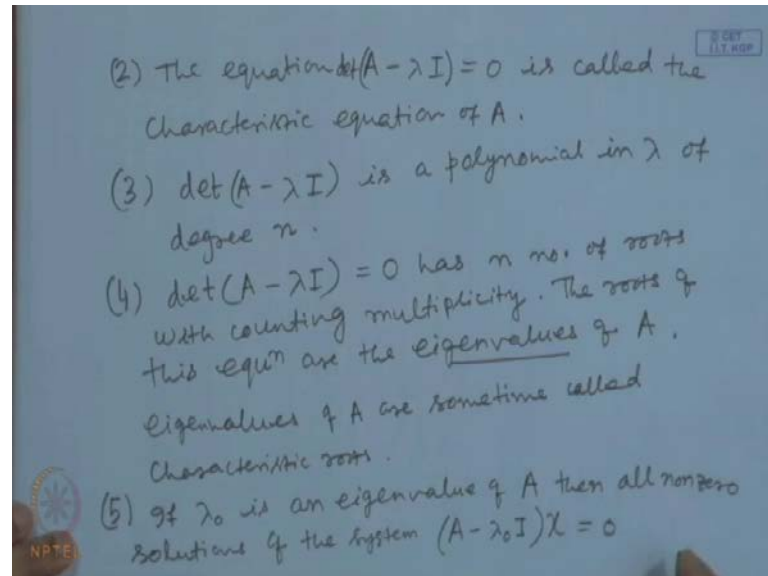

(Refer Slide Time: 00:38)

So, we will discuss about this method to find Eigen values and eigenvectors of matrices. Recall that if it become that if λ is an Eigen value of a matrix A of size n by n , then there exist a vector x in the field, in this vector space F^n such that Ax is equal to λx , here x is not the 0 vector; or you can write this as A minus λ times I x is equal to 0 , where I is at the n by n identity matrix. So, we have the following observations, that first observation is like this, if there is a non-zero solution of, if there exist a non zero vector x such that. A minus λ I x is equal to 0 , then rank of this A minus λ I is less than n , that this number of variables. So, in other words, that is A minus λ I is not invertible and that is same as which is same as determinant of A minus λ I is

equal to 0. So, from this equation we find all Eigen values of the matrix A. So, this equation.

(Refer Slide Time: 03:56)

So, this the equation A minus lambda I is equal to 0. So, the determinant of A minus lambda I is equal to 0 is called the characteristic equation of A. And this is, this determinant of A minus lambda I is a polynomial in lambda of degree n this is or degree n polynomial. So, this equation is therefore, this determinant of A minus lambda I equal to 0 has at most n distinct solutions or roots and distinct roots are with counting multiplicity, this has n number of roots with counting multiplicity. And the roots of this equation are the Eigen values of A.

So, given any matrix A therefore, we form the matrix A minus lambda I first and then take its determinant and equal to 0 and get all roots of this equation. The roots of this equation are exactly the Eigen values of the matrix A. Eigen values are also called characteristic root sometime, because of this second. So, Eigen values of A are sometime called characteristic equations sorry characteristic roots, Eigen values of A are sometimes called characteristic roots. Then next we will see how to find Eigen vectors corresponding to an Eigen value of the matrix A. If lambda 0 is an Eigen value of A then all non zero solutions of the system A minus lambda 0 I x is equal to 0 are the eigenvectors corresponding to.

(Refer Slide Time: 08:20)

Eigenvectors corresponding to the eigenvalue λ_0 .

Example : Find all eigenvalues and corresponding eigenvectors of the matrix

$$A = \begin{pmatrix} 5 & 4 & 2 \\ 4 & 5 & 2 \\ 2 & 2 & 2 \end{pmatrix}$$

Solution: The characteristic polynomial of A is $\det(A - \lambda I) = \begin{vmatrix} 5-\lambda & 4 & 2 \\ 4 & 5-\lambda & 2 \\ 2 & 2 & 2-\lambda \end{vmatrix}$

$$= -(\lambda - 10)(\lambda - 1)^2.$$

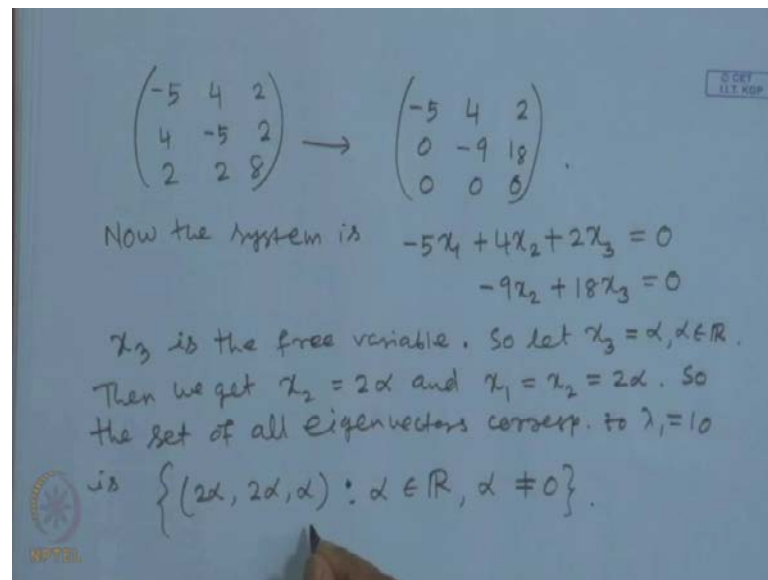

Are the eigenvectors corresponding to the Eigen value lambda 0. So, next let us see one example, where you find Eigen values and eigenvectors of matrices. So, find all Eigen values and Eigen and corresponding eigenvectors of the matrix A, that is given by 5 4 2 4 5 2 2 2 2. So, we solve like this, solution: first we find characteristic polynomial of A, the characteristic polynomial of A is determinant of A minus lambda I, here we consider I be 3 by 3 identity matrix. So, the given matrix thus A minus lambda I is therefore, 5 minus lambda 4 2 4 5 minus lambda 2 2 2 2 minus lambda and here to find out it is determinant, determinant of this matrix. And that is one gets like this after computation, one can find the determinant will like this, minus lambda minus 10 into lambda minus 1 whole square.

(Refer Slide Time: 11:21)

Now the Eigenvalues are
 $\lambda_1 = 10, \lambda_2 = 1$, where multiplicity of λ_2 is 2.
Eigenvectors corresp. to $\lambda_1 = 10$: Here we have to
solve $(A - 10I)x = 0$, where $x = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \in \mathbb{R}^3$.
or $\begin{pmatrix} -5 & 4 & 2 \\ 4 & -5 & 2 \\ 2 & 2 & -8 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = 0$
Echelon form of the co-efficient matrix will
be :

So, the roots of this equation determinant of A minus lambda I are this lambda 1 is 10 lambda 2. So, now the Eigen values are lambda 1 equal to 10 lambda 2 is equal to 1 with multiplicity 2, where multiplicity of lambda 2 is 2. So, next we shall find out eigenvectors corresponding to this Eigen values. So, eigenvectors corresponding to lambda 1 that is equal to 10 so, we find like this here, we have to solve the system, we have to solve this homogenous system A minus 10 I into this x is equal to 0, where x is this x 1 x 2 x 3 this is 3 components this is a vector in R 3 you can take. So, that is the system is like this A minus 10 I is like this, minus 5 4 2 4 minus 5 2 2 2 minus 8 and this x 1 x 2 x 3 so, this system is like this, this is equal to 0. Now, we consider echelon form of the coefficient matrix, are to find all solutions. So, the echelon form of echelon form of the co-efficient matrix will be like this.

(Refer Slide Time: 14:31)

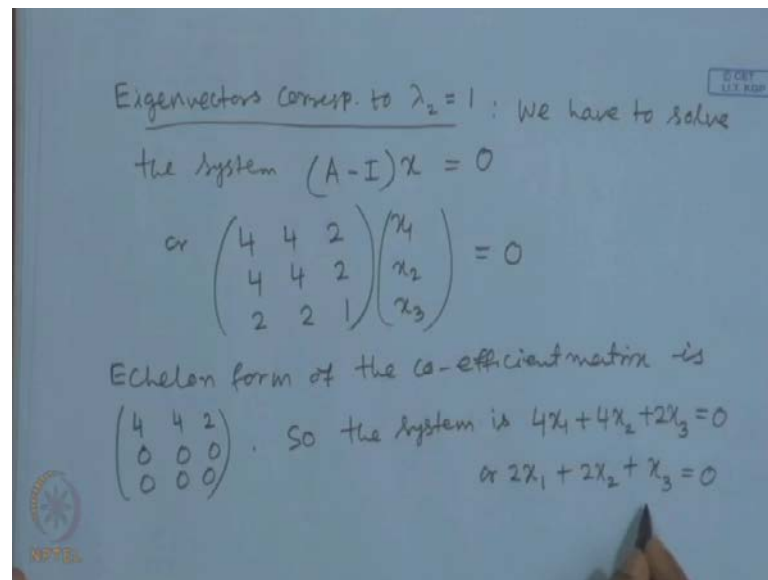

$$\begin{pmatrix} -5 & 4 & 2 \\ 4 & -5 & 2 \\ 2 & 2 & 8 \end{pmatrix} \rightarrow \begin{pmatrix} -5 & 4 & 2 \\ 0 & -9 & 18 \\ 0 & 0 & 0 \end{pmatrix}$$

Now the system is $-5x_1 + 4x_2 + 2x_3 = 0$
 $-9x_2 + 18x_3 = 0$

x_3 is the free variable. So let $x_3 = \alpha, \alpha \in \mathbb{R}$.
Then we get $x_2 = 2\alpha$ and $x_1 = x_2 = 2\alpha$. So
the set of all eigenvectors corresp. to $\lambda_1 = 10$
is $\{(2\alpha, 2\alpha, \alpha) : \alpha \in \mathbb{R}, \alpha \neq 0\}$.

Here, this coefficient matrix is minus 5 4 2 4 minus 5 2 2 2 8 and on the echelon form of this is like this, minus 5 4 2 0 minus 9 18 0 0. So, the system of the equation is now the system is minus 5 x 1 plus 4 x 2 plus 2 x 3 is equal to 0, minus 9 x 2 plus 18 x 3 is equal to 0. Here, we consider x 3 is the free variable that is a variable which is free to take any value in the field. So, let x 3 is equal to alpha, alpha belongs to R, then we get x 2 is equal to twice alpha and x 1 is also equal to that is x 2 and it is equal to twice alpha. So, the set of all eigenvectors corresponding to lambda 1 is equal to 10 is this set, where it is consist of twice alpha, twice alpha, alpha; alpha belongs to R and alpha is not equal to 0. If alpha equal to 0 then we get this vector be a zero vector and zero vector cannot be an eigenvector. So, this is the set of all eigenvectors, corresponding to the Eigen value lambda 1 is equal to 10.

(Refer Slide Time: 17:32)

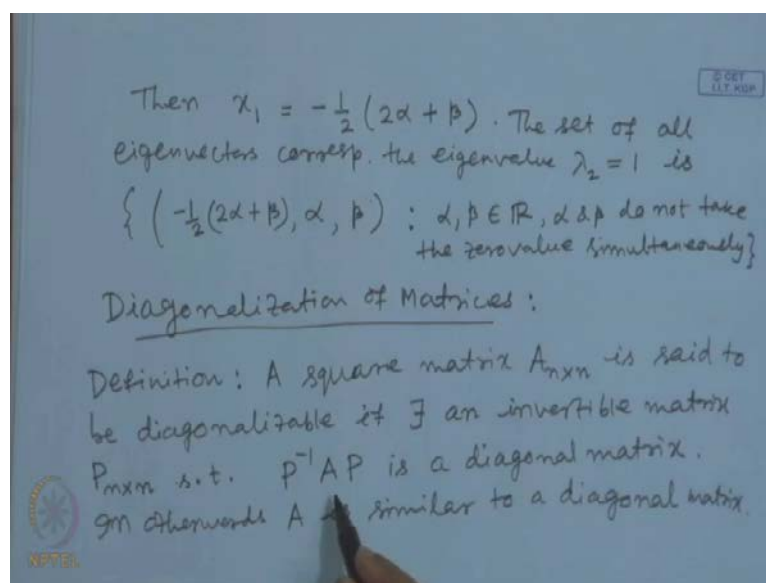

Eigenvectors corresp. to $\lambda_2 = 1$: We have to solve
the system $(A - I)x = 0$
or $\begin{pmatrix} 4 & 4 & 2 \\ 4 & 4 & 2 \\ 2 & 2 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = 0$
Echelon form of the co-efficient matrix is
 $\begin{pmatrix} 4 & 4 & 2 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$. So the system is $4x_1 + 4x_2 + 2x_3 = 0$
or $2x_1 + 2x_2 + x_3 = 0$

So, next we will find this eigenvector corresponding to lambda 2 that is equal to 1. So, here to solve the system A minus I times x is equal to 0 or it is $4 \ 4 \ 2 \ 4 \ 4 \ 2 \ 2 \ 2 \ 1 \ x \ 1 \ x \ 2 \ x \ 3$ that is equal to 0. And we get the echelon form of the coefficient matrix, we will like this echelon form of the coefficient matrix is given by $4 \ 4 \ 2 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0$. So, the system will be, the system is given by $4 \ x \ 1$ plus $4 \ x \ 2$ plus $2 \ x \ 3$ is equal to 0 or $2 \ x \ 1$ plus $2 \ x \ 2$ plus $x \ 3$ is equal to 0.

So, here we are having only one equation and three variables. So, two variables are free variables and $x \ 2$ and $x \ 3$ are therefore, free variables here, $x \ 2$ and $x \ 3$ are free variables. So, let us take that $x \ 2$ is equal to alpha and $x \ 3$ is equal to beta where alpha and beta they come from this certain real numbers, because we are considering real system, system over real numbers.

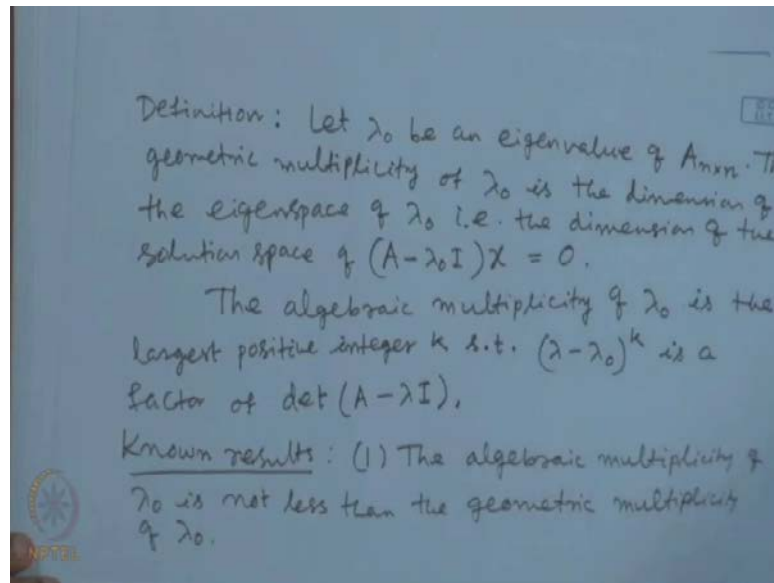

(Refer Slide Time: 20:45)

So, then we get x_1 be like this, that is minus half into twice alpha plus beta. So, now the set of all eigenvectors corresponding to the Eigen value $\lambda_2 = 1$ is equal to 1 is given by this minus half into twice alpha plus beta, alpha, beta. Where alpha beta belongs to the set of real numbers and alpha and beta do not take the zero value simultaneously otherwise this vector will be a zero vector and that cannot be an Eigen vector. So, this is how we find Eigen values and eigenvectors of matrices. So, next we shall discuss about another important concept that is diagonalization of matrices.

Here also, we consider only square matrices that, let us see first what is the meaning of diagonalization of matrices that we given this definition, A square matrix A of size n is said to be diagonalizable if, there exist an invertible matrix P of size n by n such that, $P^{-1}AP$ is a diagonal matrix. In other words this A is similar to a diagonal matrix. So, not all matrices; not all square matrices are diagonal matrices, that is not for any diagonal sorry not for any square matrix A we get an invertible matrix P so that we will have this $P^{-1}AP$ will be similar, this will be a diagonal matrix. So, here we shall see have two more on definitions or terminologies for discussion of this diagonalization of matrices.

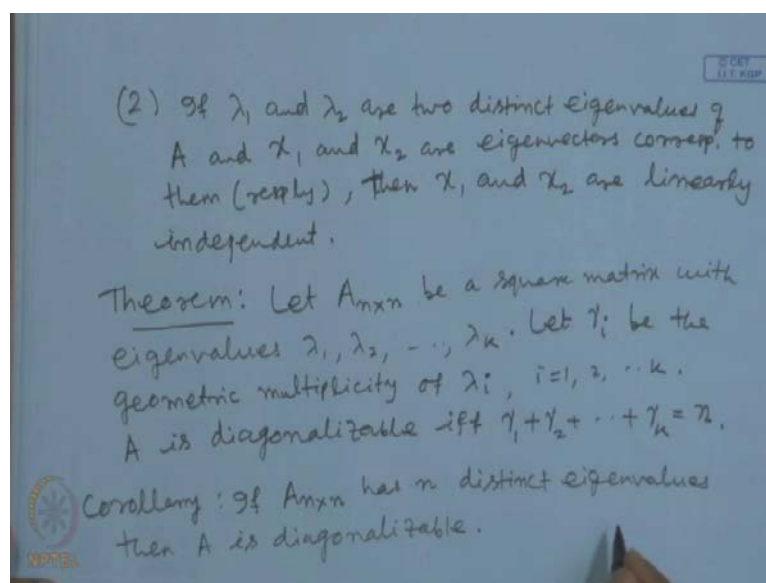

(Refer Slide Time: 25:29)

So, let us see that definition of multiplicity, geometric multiplicity and algebraic multiplicity of an Eigen value. So, let λ_0 be an Eigen value of a matrix A of size n by n . Then the geometric multiplicity of λ_0 is the dimension of the Eigen space of λ_0 . That is the dimension of the solution space of this homogenous system A minus $\lambda_0 I$ x equal to zero. Here also, we will find algebraic multiplicity of λ_0 , that is the algebraic multiplicity of λ_0 is the largest positive integer k such that $\lambda - \lambda_0$ whole to the power k is a factor of this characteristic polynomial that $A - \lambda I$ are in other words.

This is a multiplicity λ_0 is the multiplicity of I mean, this algebraic multiplicity of λ_0 it is actually multiplicity of λ_0 is a root of this characteristic equation. So, next we will just states some known results on this geometric multiplicity and algebraic multiplicities known results and also that relation among Eigen vectors corresponding to different Eigen values. So, the first one is like this the algebraic multiplicity is greater than or equal to the geometric multiplicity of an Eigen value. That the algebraic multiplicity of λ_0 is not less than the geometric multiplicity of λ_0 , then next we have another important result that we shall use is that.

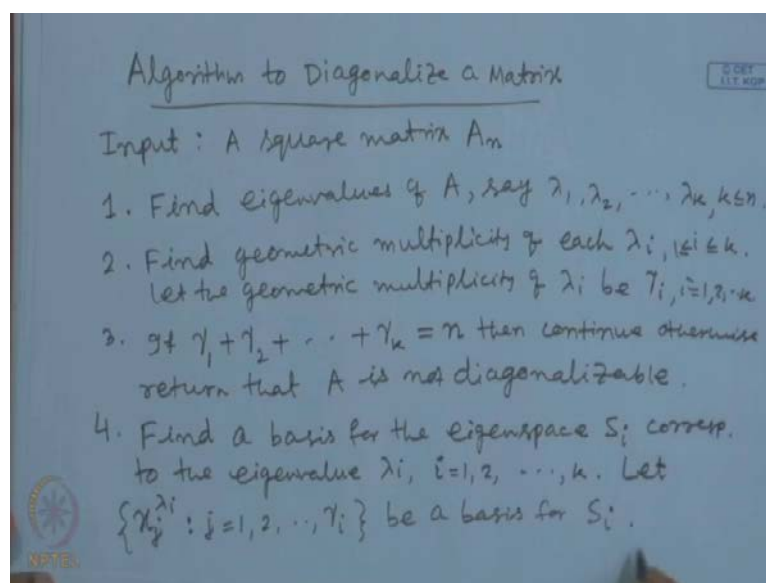

(Refer Slide Time: 29:53)

If λ_1 and λ_2 are two distinct Eigen values of A and x_1 and x_2 are eigenvectors corresponding to them respectively, then x_1 and x_2 are linearly independent. That is eigenvectors corresponding to distinct Eigen values are linearly independent one can prove this easily. So, next we shall use this results and find this diagonalization of matrices of course, here important criteria is tells about diagonalization of matrices. And here is this result that tells a necessary and sufficient condition for diagonalization of matrices.

So, let this A be a matrix of size invariant and be a square matrix, the square matrix with eigenvalues $\lambda_1, \lambda_2, \dots, \lambda_k$. Let γ_i be the geometric multiplicity of λ_i , i from 1, 2 to k . Then A is diagonalizable if and only if, this γ_1 plus γ_2 plus γ_k is equal to n that is the size of this matrix. Or in other words we can also relate this A matrix is diagonalizable if and only if, this algebraic multiplicity is equal to the geometric multiplicity of every Eigen value. So, here we are having a corollary that, one gets if this matrix of size n by n has n distinct Eigen values then A is diagonalizable, because the geometric multiplicity of an Eigen value is at least 1.

(Refer Slide Time: 34:42)

So, the next we will see, a method for diagonalization of matrices are, that we write is in algorithm to diagonalizable a matrix. So, here our input is a square matrix A of size n , then first take is this, we find eigenvalues of A say $\lambda_1, \lambda_2, \lambda_k$ here, k is less than or equal to n of course. Then second step is we find geometric multiplicity of each λ_i, i from 1 to k . Let the geometric multiplicity of λ_i be γ_i, i from 1, 2 to k . Then third step is that we check, whether the sum of the geometric multiplicities that each γ_1 plus γ_2 up to γ_k plus γ_k is equal to n , then we continue this; then continue otherwise we return that k is not diagonalizable.

So, in fourth step we find, we know the geometric multiplicity of is eigenvalue and sum of the geometric multiplicities equal to n then here, for each Eigen value we shall find a basis for the eigenspace. So, here find this is, find a basis for the eigenspace S_i corresponding to the eigenvalue λ_i , for $i = 1, 2$ up to k . So, let the basis be; let this $x_j^{\lambda_i}$ such that, j is equal to 1, 2 to γ_i be a basis for S_i . So, dimension of S_i is γ_i . So, therefore, in this set we have this γ_i number of vectors and this is basis for this eigenspace corresponding to the eigenvalue λ_i . So, here is i is therefore, from 1, 2 to k for each λ_i we consider a basis for it is eigenspace S_i .

(Refer Slide Time: 40:15)

5. Take $P = \begin{pmatrix} \gamma_1^{\lambda_1} & \dots & \gamma_1^{\lambda_k} & \gamma_2^{\lambda_1} & \dots & \gamma_2^{\lambda_k} & \dots & \gamma_n^{\lambda_1} & \dots & \gamma_n^{\lambda_k} \end{pmatrix}$

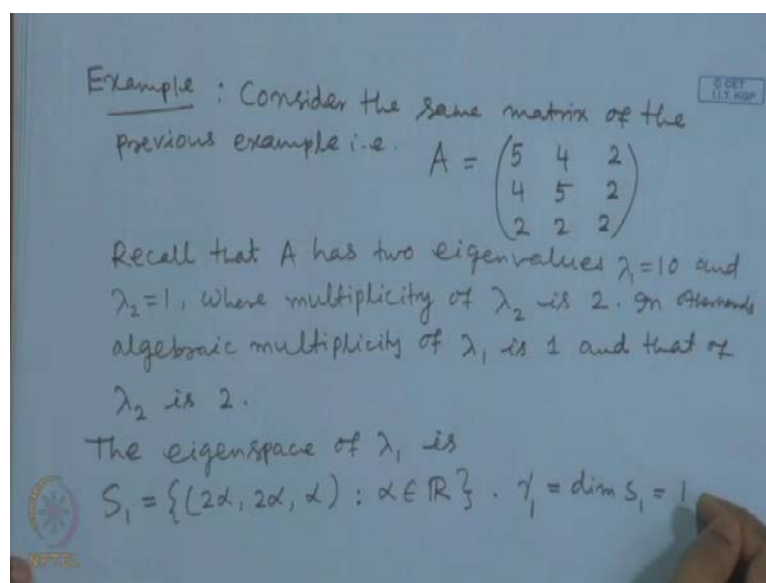

Where each $\gamma_j^{\lambda_i}$ is a column vector or a matrix of size $n \times 1$. Therefore P is a square matrix of size $n \times n$.

6. $P^{-1} A P = \begin{pmatrix} \gamma_1^{\lambda_1} \gamma_1^{\lambda_1} & & & \\ & \gamma_1^{\lambda_2} \gamma_1^{\lambda_2} & & \\ & & \ddots & \\ & & & \gamma_k^{\lambda_k} \gamma_k^{\lambda_k} & & \\ & & & & & 0 & \\ & & & & & & \ddots & \\ & & & & & & & 0 & \end{pmatrix}$

So, now this in this step, we find that invertible matrix P the like this take P be, the matrix that it is consist of $x_1 \lambda_1$ up to this $x_1 \gamma_1 \lambda_1$, then $x_1 \lambda_2$ $x_1 \gamma_2 \lambda_2$ like this, this $x_1 \lambda_k$ up to this $x_1 \gamma_k \lambda_k$. That is; this is a matrix of size n by n a is where each $x_j \lambda_i$ is a column vector or a matrix of size n by 1 . Therefore, P is a square matrix of size n by n , what is that this P each invertible matrix, because all this columns in p are linearly independent and hence this rank of this P is equal to n and therefore, it is invertible.

So, now we get that this P inverse $A P$ is equal to the matrix where in this diagonal [host/first] this $\gamma_1 \lambda_1$ in number they will be $\gamma_1 \lambda_1$ in number or λ_1 then λ_2 like this, this λ_k there $\gamma_k \lambda_k$ in number until rest are the zero matrices.

(Refer Slide Time: 43:39)

So, this is how we find a; that diagonalization of this matrix A . Let us see this example to support this algorithm, let us help this example here, we consider the same matrix of the previous example. That is A is this matrix $\begin{pmatrix} 5 & 4 & 2 \\ 4 & 5 & 2 \\ 2 & 2 & 2 \end{pmatrix}$ and also recall that this is two eigenvalues; recall that A has two eigen values λ_1 is equal to 10 and λ_2 is equal to 1, where λ_2 multiplicity of λ_2 is 2 or in other words algebraic multiplicity of λ_2 is 2. In other words algebraic multiplicity of λ_1 is 1 and that of λ_2 is 2. So, the next we shall find geometric multiplicity of λ_1 and λ_2 .

So, **again** recall that the Eigen space of λ_1 is the set S_1 that is consist of twice alpha, twice alpha, alpha. So, is that alpha belongs to \mathbb{R} . So, here including the zero vector so therefore, we do not take alpha is non zero. So, notice that dimension of that is γ_1 is dimension of S_1 that is equal to 1. This also we get again from that it value take here on. So, next we consider the eigenspace of λ_2 . So, the eigenspace of λ_2 is the set S_2 , it is consist of minus half into twice alpha plus beta, alpha, beta here, alpha beta are real numbers and the dimension of S_2 , that is geometric multiplicity of λ_2 .

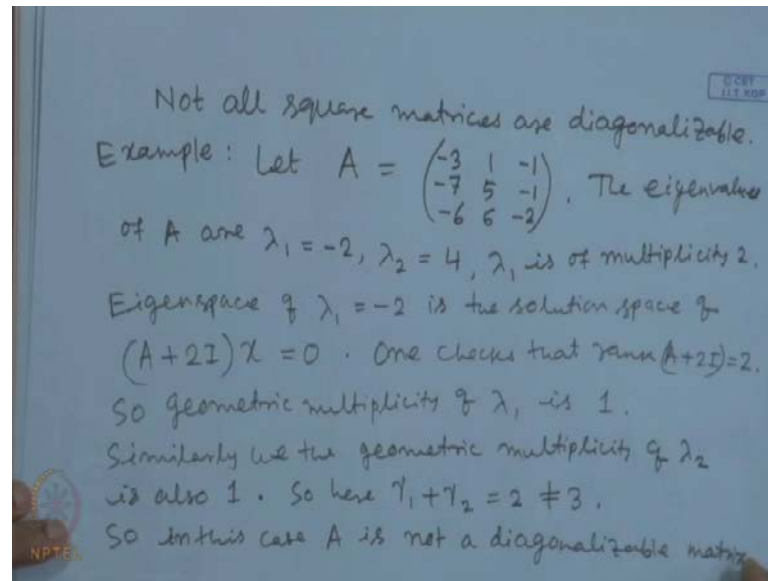

(Refer Slide Time: 48:08)

$\gamma_2 = \dim S_2 = 2$.
Now $\gamma_1 + \gamma_2 = 3 = \text{size of the matrix } A$. So
 A is diagonalizable.
A basis for S_1 is $\{(2, 2, 1)\}$. A basis for S_2
is $\{(-1, 1, 0), (-\frac{1}{2}, 0, 1)\}$ (obtained by taking
 $\alpha = 1, \beta = 0$ and then $\alpha = 0, \beta = 1$).
So $P = \begin{pmatrix} 2 & -1 & -\frac{1}{2} \\ 2 & 1 & 0 \\ 1 & 0 & 1 \end{pmatrix}$
One checks that $P^{-1}AP = \begin{pmatrix} 10 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$.

Gamma 2 is dimension of S_2 that is equal to 2. Now, this gamma 1 plus gamma 2 that is equal to 3, that is size of matrix A . So, this matrix A is diagonalizable. So, next we shall find that invertible matrix P . So, for that to you have to find a basis for S_1 . So, a basis for S_1 is its dimension is 1 so, we can take any non zero vector in this one and that will be a basis for S_1 . Then a basis for S_2 is that its dimension is 2 so therefore, it consists of two linearly independent vectors minus 1, 1, 0 and minus half, 0, 1.

That we have obtained by taking, that has been obtained by taking alpha equal to 1 beta equal to 0 and then alpha equal to 0 beta equal to 1. Now, the matrix P will be like this, we take the basis in S_1 and S_2 as columns of this matrix P . So therefore, first column will be basis for S_1 that 2 2 1 and then we write basis of S_2 . So, that is minus 1 1 0 minus half 0 1. So now, one can check that this $P^{-1}AP$ is the matrix this, the diagonal matrix 10 0 0 0 1 0 0 0 1, this is we find this matrix P to diagonalize the given matrix A .

(Refer Slide Time: 51:50)

Next will see one example that, not all matrices are diagonalizable, not all square matrices are diagonalizable. So, let us see one example of it that here we consider the matrix A be like this, that minus 3 1 minus 1 minus 7 5 minus 1 minus 6 6 minus 2. So, here one checks that the eigenvalues will like this eigenvalues of A are λ_1 is equal to minus 2, λ_2 is equal to 4 and λ_1 is of multiplicity 2. So, eigenspace of λ_1 is the solution space of here, eigenspace of λ_1 is the solutions space of the system A plus twice I x equal to 0. Here this rank of 1 can see that, this rank of A plus 2 I is equal to 2.

So, one checks that rank of A plus twice I is equal to 2. So, geometric multiplicity of λ_1 is 1 similarly, we get the geometric multiplicity of λ_2 is also 1. Therefore so here, γ_1 plus γ_2 is equal to 2 and that is not equal to 3. So, in this case A is not a diagonalizable matrix, and that (()) one, this lecture we start here and this diagonalization of matrices there also useful. And in the next lecture, we shall discuss that using diagonalizable matrices, we can also compute higher power of matrices that (()) for this lecture. Thank you.
