Lecture No. #07
Jordan Canonical Form
Cayley Hamilton Theorem

(Refer Slide Time: 00:30)

So, we shall start today about this Jordan canonical form **Jordan canonical form**. (No audio from 00:32 to 00:47) So, remember that, a square matrix of size n by n is similar to a matrix B of size n by n , if and only if there exist an invertible matrix **invertible matrix** P of size n by n , such that $P^{-1}AP$ is equal to B . So, in the previous lecture, we have seen that not all square matrices are similar to diagonal matrices; or in other words, not all square matrices are diagonalizable. But here we shall see that every square matrix is similar to a matrix that is nearly diagonal.

So, nearly diagonal means; it is of the form that **the diagonal entries** besides the diagonal entries, the super diagonal entries are not zero, and they are equal to 1. At the most that is, we are talking about that every square matrix is similar to a matrix that is in Jordan canonical form. So, here we shall define a Jordan block that for any scalar α , a

Jordan block of size k denoted by $J_k(\alpha)$ is a matrix is a k by k matrix of the form; this $J_k(\alpha)$, it is of the form that the diagonal entries are α and the super diagonal entries they are equal to 1 that is, the super diagonal entries are equal to 1. So, this called a Jordan block. And the next, we shall define a Jordan block matrix or a Jordan canonical form.

(Refer Slide Time: 04:16)

Our next definition is this, that a square matrix a square matrix A is called a Jordan block matrix Jordan block or in Jordan canonical form Jordan canonical form, if it is it is a diagonal matrix diagonal matrix or any one of any of the following part that is, here this is a diagonal matrix, and this $J_k(\alpha)$; like this $J_k(\alpha)$ or it is of this form that $J_k(\alpha)$ up to this $J_k(\alpha)$. where this D is a diagonal matrix of course, the half diagonal entries, or this blocks half diagonal blocks, they are all zero blocks. Basically this is, this two are block matrices that the diagonal blocks are like this and half diagonal blocks are zero. And here D is a diagonal matrix. So, we shall show that here we shall show that every square matrix square matrix is similar to a Jordan block matrix

(Refer Slide Time: 07:14)

So, let us see some example of Jordan block matrices; that look at this example. Here we consider the matrices **consider the matrices** A_1 is like this, it is of size 5 by 5, and entries are 2 1 0 0 0 0 2 1 0 0 0 0 2 0 0 0 0 2 1 and this 0 0 0 0 and this 2. So, here this matrix A_1 is in Jordan form, that is a Jordan block matrix, **or it is in matrix** or it is in Jordan canonical form **canonical form** because it is of the form A_1 is of the form that, here we can say this as first this 3 by 3 sub-matrix that forms $J_{3,2}$ and this **this one** 2 by 2 sub-matrix that forms $J_{2,2}$, and the remaining are zero blocks.

But this matrix, if we consider A_2 be like this, this is 2 0 1 0 0 2 1 0 0 0 2 1 0 0 0 2 is not in Jordan canonical form in **Jordan canonical form**, because of this entry that because of **because of the** third entry in first row. So, this is not a super diagonal entry and this not equal to zero. So, therefore, this is not in Jordan canonical form. So, here we shall discuss that how to find Jordan canonical form of every square matrix. And for that, we shall define another terminology that is called generalized eigenvector.

(Refer Slide Time: 11:16)

So, here we define generalized eigenvectors of square matrices. So, here **all** we consider, let A be a square matrix over a field F and let λ be an eigenvalue of A , then **non-zero vector or** a non-zero vector x in F^n is a **generalized** generalized eigenvector of A corresponding to λ **corresponding to λ** , if of course this x is a generalized eigenvector of we take **type m** type m of A corresponding to λ , if this $(A - \lambda I)^m x = 0$ but $(A - \lambda I)^{m-1} x \neq 0$. So, this is called type m generalized eigenvectors of A corresponding to λ .

So, notice that type one generalized eigenvectors are ordinary vectors. So, notice that type one generalized eigenvectors are ordinary eigenvectors. So, this is why this name generalized is their. Then we shall see here a chain generated by a generalized eigenvectors. So, that is important here for finding Jordan canonical form. So, we get this chain generated by a generalized eigenvector. And here we consider that, **we consider** x_m let x_m be a generalized eigenvector of type m of a matrix, square matrix A with respect to eigenvalue λ . Then we get a chain that is generated by x_m ; this generalized eigenvector x_m . And here we define the chain be like this.

(Refer Slide Time: 15:34)

Let $x_{m-1} = (A - \lambda I) x_m$
 $x_{m-2} = (A - \lambda I)^2 x_m = (A - \lambda I) x_{m-1}$
 $\vdots$
 $x_2 = (A - \lambda I)^{m-2} x_m = (A - \lambda I) x_3$
 $x_1 = (A - \lambda I)^{m-1} x_m = (A - \lambda I) x_2$

$S = \{x_1, x_2, \dots, x_{m-1}, x_m\}$ is called the chain generated by x_m .

Properties of this chain:

- (1) Every $x_j, j = 1, 2, \dots, m$ is non-zero vector.
- (2) x_j is a g.e.v. of type j corresp. λ .

Let x_{m-1} is equal to $A - \lambda I$ times x_m . x_{m-2} is $A - \lambda I$ whole square times x_m , and that is equal to $A - \lambda I$ times x_{m-1} . In this fashion we get this x_2 be $A - \lambda I$ whole to the power $m-2$ times x_m , or this is equal to $A - \lambda I$ times x_3 . And finally, we get this x_1 ; x_1 is equal to $A - \lambda I$ whole to the power $m-1$ times x_m , and that is equal to $A - \lambda I$ times x_2 . So, this set S consisting of vectors x_1, x_2 up to x_{m-1}, x_m is called the chain generated by x_m .

So, this chain generated by x_m satisfy some properties. And we shall list those properties here. So, properties of this chain are like this: First Properties is that **every x_j well** every x_j is non-zero every x_j, j from 1, 2 up to m is non-zero vector **is non-zero vector**. This follows from definition of this generalized eigenvalue x_m , because x_m is a generalized eigenvalue of type m . So this is important. And this second property is that every x_j **here this x_j x_j** is a generalized eigenvector of type j of the matrix A ; type j corresponding to λ . So, every x_j is a generalized eigenvector of type j corresponding to λ .

(Refer Slide Time: 19:20)

So then another important property here is this one that, this sequence consisting of this sequence of vectors x_1, x_2 to x_m or this set S , this is a linearly independent set. The chain S of vectors of x_1, x_2 up to x_m is a linearly independent set **linearly independent set** and this property one can also check easily. Then next, we shall see using this generalized eigenvectors, how to get a basis for a matrix A . That is called canonical basis for a matrix. So, here we shall write those results, known results; we shall use these results for finding Jordan canonical form of a matrix. So, it says that every n by n matrix A possessed n linearly independent generalized eigenvectors, **n linearly independent generalized generalized eigenvectors** and in short forms we write them as liges - linearly independent generalized eigenvectors. This liges **this liges** is called a canonical basis for A **a canonical basis for this matrix A**

So, let us take this be first result. Then the second result is like this. A generalized eigenvectors corresponding to distinct eigenvalues are linearly independent. So, it says that generalized eigenvectors **corresponding to** corresponding to distinct eigenvalues **distinct eigenvalues** are linearly independent. This property is like this properties of ordinary eigenvectors. So, another important property is that if λ is an eigenvalue of A with **algebraic** algebraic multiplicity **multiplicity** k , then A will have k liges or **k linearly independent** k linearly independent generalized eigenvectors or liges. So, corresponding to every eigenvalue; that means, if the algebraic multiplicity of λ is k , then we get k linearly independent generalized eigenvectors corresponding to λ

here this independent generalized eigenvectors corresponding to lambda. So, this is very useful.

(Refer Slide Time: 24:45)

So, next let us see how to find a canonical basis for a matrix a square matrix and this is important method to it find a canonical basis for square matrix A . So, here we consider that A be a matrix of size n by n . So, here first step is, we find all the eigenvalues of A find all the eigenvalues of A , say λ_1, λ_2 up to λ_k with algebraic multiplicity algebraic multiplicity m_1, m_2 up to m_k respectively. So, then next for this every i from $1, 2$ up to k , we find find the smallest positive integer p_i , such that this A minus $\lambda_i I$ whole to the power p_i has rank n minus m_i , so after getting this p_i for every k , or for every l from $1, 2$ up to this p_i .

Let row l be defined like this that row l is defined like this this is the equal to rank of a minus λ_i multiplied by I whole to the power l minus 1 minus rank of A minus $\lambda_i I$ whole to the power l . of course, here we consider this we take this A minus $\lambda_i I$ whole to the power zero be the identity matrix. So, this row l we have defined this plays important role, that this then this matrix A ; then in the canonical basis canonical basis of A . There are row l lges - linearly independent generalized eigenvectors of type l corresponding to corresponding to eigenvalue λ_i .

(Refer Slide Time: 28:48)

Then in the canonical basis of A there are p_l lines of type l corresp. to λ_i .
 Next we explain the method for finding a canonical basis for A by taking an example below.
 Example: Find a canonical basis for

$$A = \begin{pmatrix} 4 & 0 & 1 & 0 \\ 2 & 2 & 3 & 0 \\ -1 & 0 & 2 & 0 \\ 4 & 0 & 1 & 2 \end{pmatrix}$$

Let β be a canonical basis for A . The eigenvalues of A are $\lambda_1 = 3, \lambda_2 = 2$ with multiplicities (alg) $m_1 = 2, m_2 = 2$.

Then **next we explain** next we explain the method for finding a canonical basis for A **by taking an example** by taking an example below, and **this example** in this example we consider, find a canonical basis for this matrix A is like this: $4 \ 0 \ 1 \ 0 \ 2 \ 2 \ 3 \ 0$ minus $1 \ 0 \ 2 \ 0 \ 4 \ 0 \ 1 \ 2$, so this is zero. So, here we find a canonical basis for A in the following manner. Let B be a canonical basis for A . So, first we compute **the eigenvalues** the eigenvalues of this matrix A are $\lambda_1 = 3, \lambda_2 = 2$ **with multiplicity** with multiplicities that is **algebraic only** algebraic multiplicity $m_1 = 2, m_2 = 2$.

(Refer Slide Time: 32:15)

Consider the eigenvalue $\lambda_1 = 3$: $p_1 = 2, f_2 = 1, f_1 = 1$.
 So β contains one g.e.v., say x_1 , of type 1 and one g.e.v., say x_2 , of type 2. $\{x_1, x_2\}$ is a lines corresp. to λ_1 . We shall find out x_1 and x_2 .
 $x_1 = (A - 3I)x_2, (A - 3I)^2 x_2 = 0$

$$\text{or } \begin{pmatrix} 0 & 0 & 0 & 0 \\ -3 & 1 & -4 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & 2 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} = 0, \quad x_2 = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix}$$

or $-3x_1 + x_2 - 4x_3 = 0$
 $-x_1 + 2x_3 + x_4 = 0$

x_2 can be taken as $x_2 = \begin{pmatrix} 1 \\ 3 \\ 0 \\ 1 \end{pmatrix}$.

Here we shall find out this generalized eigenvectors x_1 and x_2 . So, in this manner, well x_1 is actually A minus $3I$ times this x_2 and this A minus $3I$ whole square x_2 that is equal to zero; this x_2 is a generalized eigenvector of type 2 this. So, therefore, this x_2 satisfies this equation. And here we consider x_1 be **this eigenvector** generalized eigenvector of type 1. Then for finding this x_2 we get this or we get this A minus $3I$ whole square, **one can compute is like this it is the matrix** first row is all zero, second row is minus 3 1 minus 4 0 **then** 0 0 0 0 minus 1 0 2 1. And here for x_2 we consider the entries from $x_1 \times 2 \times 3 \times 4$, this is equal to zero.

Here we are considering this x_2 is this vector $x_1 \times 2 \times 3 \times 4$, **or we get this system is like this** or we get two equation in this system that: minus 3 x_1 plus x_2 minus 4 x_3 is equal to zero, and this minus x_1 plus 2 x_3 plus x_4 is equal to zero. So, x_2 is a solution of this system. So, we can take or also we can find x_2 can be taken as this x_2 satisfies these two equations, and we can consider this or we can solve for this also. So, let us take this x_2 be like this, that it is the vector 1 3 0 1.

(Refer Slide Time: 37:28)

$$X_1 = (A - 3I)X_2 = \begin{pmatrix} 1 \\ -1 \\ -1 \\ 3 \end{pmatrix}$$

Consider the eigenvalue $\lambda_2 = 2$: $p_2 = 1$, $q_1 = 2$.
 There are two g.e.v. of type 1 corresp. to λ_2 .
 Two linearly independent eigenvectors corresp. to λ_2 are

$$Y_1 = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix}, \quad Z_1 = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}$$

Now $B = \{Y_1, Z_1, X_1, X_2\}$ is a canonical basis for A .

So, next we can find this X_1 is from X_2 and it is like this X_1 is A minus $3I$ times X_2 , so, one compute it well. We are considering this for X_2 . So, we get this X_1 be the vector 1 minus 1 minus 1 3. So, now we have got this X_1 and X_2 . So, next we shall find out generalized eigenvectors for the second eigenvalue; consider the eigenvalue λ_2 , and that is 2. So, for this we can see that one can check this value of p_2 is equal to

1 and value of ρ_1 is equal to 2. So, this means that; there are generalized eigenvectors of this means that, there are two generalized eigenvectors of type 1 corresponding to λ_2 corresponding to λ_2 and since the generalized eigenvectors are type 1, they are ordinary eigenvectors corresponding to λ_2 .

So, we find two linearly independent eigenvectors corresponding to λ_2 , so two linearly independent two linearly independent corresponding to λ_2 one can find this is. Say, one is Y_1 and one may take this Y_1 as $\begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix}$; say this one is Y_1 , and this Z_1 that one take as $\begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}$. So, now this canonical basis corresponding to A be like this; this B consisting of Y_1, Z_1, X_1, X_2 is a canonical basis for the matrix A ; of course,, there may be several canonical basis corresponding to a matrix A .

(Refer Slide Time: 41:12)

So the next we find Jordan canonical form of a square matrix. Now we are ready to find Jordan canonical form of a square matrix. So, the method is like this; method to find Jordan method to find Jordan canonical form of a square matrix A of size n . So, this steps are like this; first step is, we find a canonical basis S or may be B we can say; find a canonical basis B of this matrix A . Second step is that, we form a matrix M that we say modal matrix form modal matrix M for A taking vectors in B as columns, such that of course, the chains consisting of single vector appear at the beginning at the beginning at the beginning of A at the beginning of this matrix M . And second condition is that, each chain appears in M in order of increasing type. We take an example and explain this of

course, so now this $M^{-1} A M$ is the Jordan form of this matrix A . This is the **Jordan** **this is the** Jordan canonical form of matrix A .

(Refer Slide Time: 45:00)

For example consider the matrix in the previous example i.e. $A = \begin{pmatrix} 4 & 0 & 1 & 0 \\ 2 & 2 & 3 & 0 \\ -1 & 0 & 2 & 0 \\ 4 & 0 & 1 & 2 \end{pmatrix}$

From the canonical basis B of A we form the modal matrix M as

$$M = (Y_1, Z_1, X_1, X_2) = \begin{pmatrix} 0 & 0 & 1 & 1 \\ 1 & 0 & -1 & 3 \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 3 & 1 \end{pmatrix}$$

Now one checks that

$$M^{-1} A M = \begin{pmatrix} 2 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 3 & 1 \\ 0 & 0 & 0 & 3 \end{pmatrix}$$

is the Jordan canonical form of the matrix A .

So, next, we take one example. For example, we consider **consider** the matrix in the previous example that is, A is the matrix **this one** that: **4 2** sorry 4 0 1 0 2 2 3 0 minus 1 0 2 0 4 0 1 2. So, for this matrix you recall that we have already got a canonical basis. So, remember that **that** the canonical basis we have got. So, now we can form model matrix from the canonical basis **canonical basis** B of A , we form the model matrix M as M consist of that Y_1 because this is consist of this chain is consist of only one vector that is Y_1 . So, Y_1 also only one vector in this chain, and then X_1 and X_2 . So, here this X_1 and X_2 form a chain and we have to write in their increasing type; that means, X_1 is type 1 and X_2 is type 2.

So, therefore, we get this model matrix M be like this; Y_1 we have taken as $0 \ 1 \ 0 \ 0$; Z_1 we have taken that $0 \ 0 \ 0 \ 1$; and X_1 is $1 \ -1 \ -1 \ 3$; and X_2 is $1 \ 3 \ 0 \ 1$. So, now one can check that, **now one checks that** this $M^{-1} A M$ is consist of the matrix of the form that it is consisting of $2 \ 0 \ 0 \ 0 \ 0 \ 2 \ 0 \ 0 \ 0 \ 0 \ 3 \ 1 \ 0 \ 0 \ 0 \ 3$, and **this is the** this matrix is the Jordan canonical form of the matrix A that is, A is similar to a Jordan block matrix. So, here we have shown that every square matrix is similar to a nearly diagonal matrix or a matrix in Jordan canonical form.

(Refer Slide Time: 50:00)

So, next, we will discuss an important theorem of this linear algebra; and in particular, this is an important theorem **theorem** of matrix theory to complete this vector space part. So, here we discuss about this Cayley-Hamilton theorem **Cayley-Hamilton theorem**. So, this is an important theorem in matrix theory **this is an important theorem in matrix theory**. So to complete this vector space part, we discuss about this theorem this is an important theorem in matrix theory. So, this Cayley-Hamilton theorem states like this, **this is Cayley-Hamilton theorem** that every square matrix **every square matrix** satisfies its own characteristic equation that is, if the characteristic equation of this matrix A of size n is $\chi_A(\lambda) = a_0 + a_1 \lambda + \dots + a_{n-1} \lambda^{n-1} + \lambda^n = 0$, then $\chi_A(A) = a_0 I + a_1 A + \dots + a_{n-1} A^{n-1} + A^n = O_{n \times n}$.

This $\chi_A(A)$ will be a_0 times identity matrix plus $a_1 A$ up to $a_{n-1} A^{n-1}$ plus A^n is the 0 matrix; this is n by n 0 matrix. So, let us see one example. If let A be the matrix $\begin{pmatrix} 1 & 2 \\ 4 & 3 \end{pmatrix}$ at characteristic equation is $\chi_A(\lambda) = \lambda^2 - 4\lambda - 5 = 0$; characteristic equation is $\lambda^2 - 4\lambda - 5 = 0$ is equal to zero.

(Refer Slide Time: 53:26)

$$\begin{aligned} X_A(A) &= A^2 - 4A - 5I \\ &= \begin{pmatrix} 9 & 8 \\ 16 & 17 \end{pmatrix} - \begin{pmatrix} 4 & 8 \\ 16 & 12 \end{pmatrix} - \begin{pmatrix} 5 & 0 \\ 0 & 5 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} \end{aligned}$$

Example: Let $A = \begin{pmatrix} 1 & 1 \\ -1 & 3 \end{pmatrix}$. Using Cayley-Hamilton theorem determine A^{-1} (if exists) and also A^6 .

Solⁿ: $\det A \neq 0$, so A^{-1} exists.

$$X_A(\lambda) = \lambda^2 - 4\lambda + 4. \text{ From Cayley-Hamilton}$$

Th^m $X_A(A) = A^2 - 4A + 4I = 0$

So, now, we shall find out $\pi_A(A)$, and that is equal to A square minus $4A$ minus $5I$, and it is the matrix that: $9 \ 8 \ 16 \ 17$ minus $4 \ 8 \ 16 \ 12$ minus $5 \ 0 \ 0 \ 5$, and one can check that this is equal to the 0 matrix of size two. So, using this Cayley-Hamilton theorem we can find higher power of matrices; we can also compute inverse of a matrix. So, this Cayley-Hamilton theorem is very useful. Let us see one example in support of this. So using, here we consider A be the matrix $1 \ 1$ minus $1 \ 3$.

So, using Cayley-Hamilton theorem **Cayley-Hamilton theorem** of determined A inverse if exists, and also sixth power of A . So, we can use this Cayley-Hamilton; note that, determinant of A is not equal to 0 . So, A inverse exists. So here, characteristic polynomial of this matrix A is λ square minus 4λ plus 4 . So, from Cayley-Hamilton theorem **from Cayley-Hamilton theorem**, we get that $\pi_A(A)$, that is equal to A Square minus $4A$ plus 4 times identity matrix is 0 .

(Refer Slide Time: 56:27)

$$\begin{aligned} \text{or } A^2 - 4A &= -4I \\ \text{or } I &= A\left(I - \frac{1}{4}A\right) \text{ or } A^{-1} = I - \frac{1}{4}A \\ \text{So } A^{-1} &= \begin{pmatrix} \frac{3}{4} & -\frac{1}{4} \\ \frac{1}{4} & \frac{1}{4} \end{pmatrix} \\ \text{To find } A^6, & \text{ we divide } \lambda^6 \text{ by } \chi_A(\lambda) = \lambda^2 - 4\lambda + 4 \\ \text{i.e. } \lambda^6 &= (\lambda^2 - 4\lambda + 4)(\lambda^4 + 4\lambda^3 + 12\lambda^2 + 32\lambda + 80) \\ &\quad + 192\lambda - 320 \\ A^6 &= 192A - 320I = \begin{pmatrix} -128 & 192 \\ -192 & 256 \end{pmatrix} \end{aligned}$$

Or from here we get that, this A square minus $4A$ is equal to minus 4 times identity or on simplifying we get that I is equal to A times I minus 1 by $4A$ or this A inverse is the matrix I minus 1 by $4A$. So now, we know the matrix A and we know this identity matrix. So, we can find the inverse of A . And it is, one can compute like this: 3 by 4 minus 1 by 4 1 by 4 1 by 4 . So, equate both the value of A in place of λ , we get this first term equal to 0 , and therefore, we get the A to the power 6 is equal to 192 times A minus 320 times identity. And one can compute that this matrix is like given by minus 128 192 minus 192 256 . This is how we have computed sixth power of this matrix A . And using in this way that mean; we can use Cayley-Hamilton theorem in this fashion, and find higher power of matrices and also inverse of matrices. And this is lots of application.

So, we stop this lecture here.

And that is all thank you.
