**Finite Difference Approximations to Hyperbolic PDEs- I**

Hello, in the last class we learnt about elliptic PDE's and few techniques, so with this we covered parabolic elliptic PDE's. Now, let us move on to hyperbolic, so before we go for finite difference approximations, it is worth to spend few minutes on the corresponding analytical treatment in brief. So, the typical example of hyperbolic PDE which is generally taught in first course is wave equation, so let us review wave equation and then proceed to the corresponding finite difference approximations.

(Refer Slide Time: 00:59)

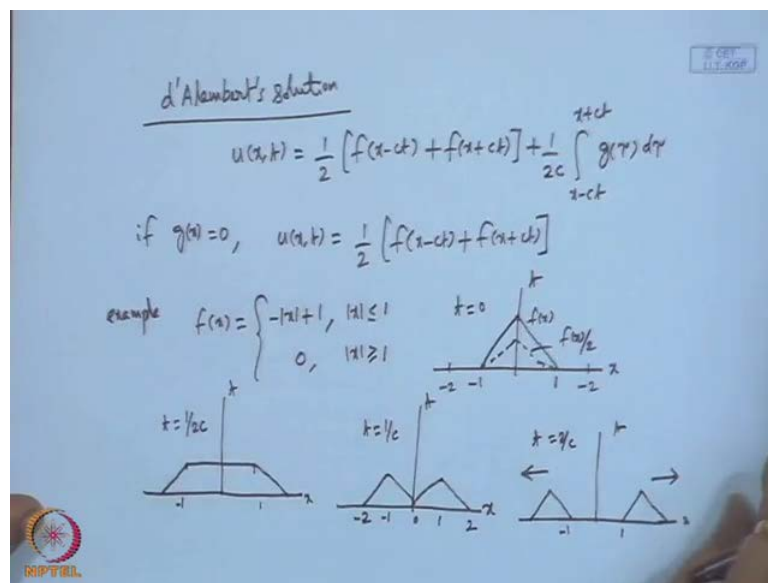

So, we review wave equation which is defined as this infinite string problem and we have various versions fixed at one end. For example, if it is fixed at one end, then one end will be infinity; other end will be the corresponding point where it is fixed at both ends. So, then it will be an interval  $a$  to  $b$ , now we have to define the complete problem by specifying the corresponding initial boundary conditions. So, we have these are initial conditions, so what are these specifications, so here the dependent variable  $u$  denote displacement, so  $\text{d}u$  by  $\text{d}t$ . So, this denote velocity, so the initial conditions are

given initial displacement  $f$  of  $x$  initial velocity  $g$  of  $x$ , so we are looking for the solution and in the present case since it is infinity I would like to put it.

So, this displacement is typical though for fixed boundaries one may have a function of  $t$ , but in general for field if you see displacements are generally vanishing displacements. If you take for example, if you fix and then pull, so you will have vibrations then maybe they will die down slowly. So, you have some vibrations back and forth and then at far field they die down, so this is a complete definition of the problem.

(Refer Slide Time: 04:03)

From analytical point of view, there is a popular solution known as d'Alembert's solution, so this is given by plus 1 by 2 c, so with this given initial velocity as  $f$  of  $x$ , sorry initial displacement is  $f$  of  $x$  and initial velocity is  $g$  of  $x$ . Then the solution is given by this if  $g$  of  $x$  is 0, that is initial velocity is 0, then  $u$  of  $x$   $t$  is, so this will be the solution. So, this represents two waves each equal to  $f$  of  $x$  by 2  $c$ , one to the left and one to the right.

So, for example, let us consider some initial profile say  $f$  of  $x$  is given by such a profile is given, then what would happen, so this is  $x$  axis and  $t$  axis. So, we have minus 1, 1, so this is  $f$  of  $x$ , so these are  $f$  of  $x$  by 2 say this, so this is at  $p$  equals to 0 which is this profile. So, then what would happen correspondingly, so this is at  $t$  equal to 1 by 2  $c$  and further, so this is at  $t$  equals to 1 by  $c$ , so then again after some time this is at  $t$  equals to this initial profile.

As time progresses, one wave pass to the left, another wave passes to the right, so this is popular d'Alembert's solution which explains the physical significance of the solution. So, similarly there could be other case corresponding to  $f(x) = 0$ , so this is a special case.

(Refer Slide Time: 08:33)

Handwritten mathematical derivation on a blue background:

$$\text{if } f(x) = 0, \quad u(x,t) = \frac{1}{2c} \int_{x-ct}^{x+ct} g(\tau) d\tau$$

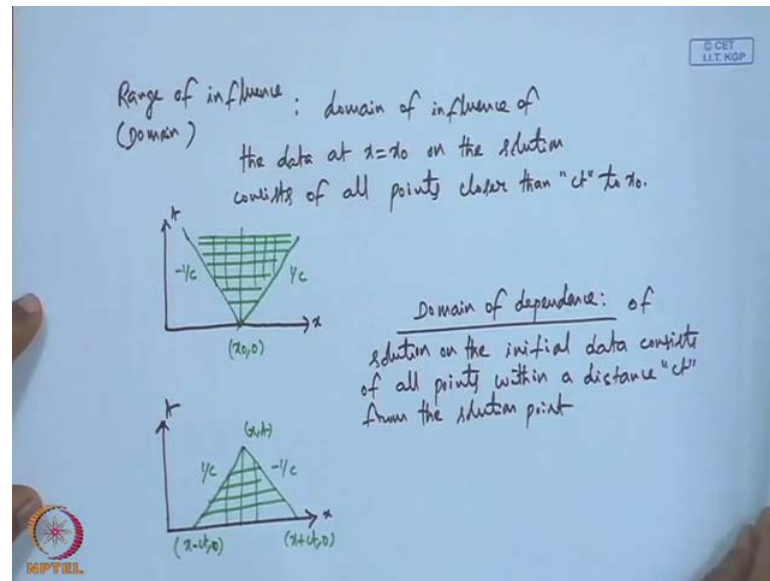

$$= \frac{1}{2} [G(x+ct) - G(x-ct)]$$

$$G(x) = \frac{1}{c} \int_{-x}^x g(\tau) d\tau$$

Below the equations, a diagram shows a horizontal line with three triangular pulses. The central pulse is the highest. Two arrows point outwards from the center, one to the left and one to the right, indicating the direction of wave propagation.

Suppose, if  $f(x) = 0$ , then we have  $u(x,t)$ , so this will be where  $g(x)$  is again for a given initial  $g(x)$ . We can see how it progresses, so this at least it is useful to understand the analytical solution which is d'Alembert's solution and the corresponding physical significance. Now, when you see the waves are passing one to the left and one to the right, so initially when we have given initial, so this point has been displaced to the maximum extent.

(Refer Slide Time: 10:07)

So, now it is useful to understand something called range of influence sometimes domain of influence, so which means domain of influence of the data at  $x$  equal to  $x_0$  initial point on the solution. So, this domain of influence of the data at  $x$  equal to  $x_0$  on the solution, so this consists of all points closer than  $ct$  to  $x_0$ . So, what do mean by that, suppose if we take initial point, then domain of influence of the data at  $x$  equal to  $x_0$  on the solution.

This means how far this would influence the solution this is with slope; these are the corresponding slopes, so this is the domain of influence of  $x_0$  on the solution. Similarly, we have domain of dependence of solution on the initial data, so this consists of all points within a distance  $ct$  from the solution point. So, this is range domain of influence of  $x_0$  on the solution and here it is the opposite so domain of dependence of solution on the initial data. So, this would be these are  $x - ct$   $x + ct$  and this point  $x_0, t_0$  solution point.

So, this domain of dependence of solution on the initial data consists of all points within a distance  $ct$  solution data, so this solution depends on the initial data within this range. So, these are few important remarks about the wave equation, now let us proceed to the finite differences scheme. So, to start with we go for our usual approximation and then see what will happen, under what condition we go for explicit and under what condition we may arrive at implicit scheme, so let us start with simple normal usual discretation.

(Refer Slide Time: 15:07)

Finite difference - Wave equation

© CET  
I.I.T. KGP

$$\frac{\partial^2 u}{\partial x^2} - \frac{1}{c^2} \frac{\partial^2 u}{\partial t^2} = 0, \quad \text{i.c.: } \begin{aligned} u(x,0) &= f(x) \\ \frac{\partial u}{\partial t}(x,0) &= g(x) \end{aligned}$$

central

b.c. suitable (depends on the domain)

- fixed at both ends  $u(a,t) = u_a$   
 $u(b,t) = u_b$

$$\frac{u_{i+1,j} - 2u_{i,j} + u_{i-1,j}}{h^2} = \frac{1}{c^2} \frac{u_{i,j+1} - 2u_{i,j} + u_{i,j-1}}{k^2} \quad (*)$$

NPTEL

So, finite differences wave equation consider with initial conditions on the boundary conditions. So, when I say suitable, this depends on the problem, so this depends on the on the domain, so for example, if it is fixed at both ends, then what we expect U of a t is some U a, U of b t is some U b. They can be in functions of t, now we discretize this so go for central, so then we arrive at.

(Refer Slide Time: 17:46)

$$\Rightarrow u_{i,j+1} = 2(1-\lambda^2)u_{i,j} + \lambda^2(u_{i+1,j} + u_{i-1,j}) - u_{i,j-1}$$

$\lambda = \frac{kc}{h}$

if the data at levels j and j-1 are available, one can compute the values at level (j+1).  
"Explicit" three level

NPTEL

Now, this we can simplify, so if we simplify where lambda equals to k c by h, so if what we have done we just adjusted. So, this is we need at higher time level, so we have

written this to the left hand side and the remaining terms got adjusted, so when we take this  $h^2$ . So,  $h$  by  $ck$   $h$  by  $ck$  is on our  $\lambda$ , so accordingly that got adjusted  $c^2$  square by  $k^2$  square comes here, so  $ck$  by  $h$  whole square which is  $\lambda^2$  square then got adjusted. So, the remark here is the coefficients are as follows, the grid is as follows, so this is  $i, j, i+k, i+1, j, i-1, j$  then  $i, j, i-1$  and we are looking for the value here. Interestingly, if we see the right hand side it is asking data at two time levels, so if the data at levels  $j$  and  $j-1$  are available one can compute the values at level  $j+1$ . Hence, this is explicit in the sense, however three levels are involved, so let us have a quick look at the corresponding error involved, so let us expand this equation.

(Refer Slide Time: 21:22)

$$u_{i,j+1} - 2(1-\lambda^2)u_{i,j} - \lambda^2(u_{i-1,j} + u_{i+1,j}) + u_{i,j-1} = 0$$

$$u_{i,j} + \frac{k}{2} \frac{\partial u}{\partial t} + \frac{k^2}{2} \frac{\partial^2 u}{\partial t^2} + \frac{k^3}{6} \frac{\partial^3 u}{\partial t^3} + \frac{k^4}{24} \frac{\partial^4 u}{\partial t^4} + \dots -$$

$$- 2(1-\lambda^2)u_{i,j}$$

$$- \lambda^2 \left( u_{i,j} - \frac{h}{2} \frac{\partial u}{\partial x} + \frac{h^2}{2} \frac{\partial^2 u}{\partial x^2} - \frac{h^3}{6} \frac{\partial^3 u}{\partial x^3} + \frac{h^4}{24} \frac{\partial^4 u}{\partial x^4} - \dots \right)$$

$$- \lambda^2 \left( u_{i,j} + \frac{h}{2} \frac{\partial u}{\partial x} + \frac{h^2}{2} \frac{\partial^2 u}{\partial x^2} + \frac{h^3}{6} \frac{\partial^3 u}{\partial x^3} + \frac{h^4}{24} \frac{\partial^4 u}{\partial x^4} + \dots \right)$$

$$+ u_{i,j} - \frac{k}{2} \frac{\partial u}{\partial t} + \frac{k^2}{2} \frac{\partial^2 u}{\partial t^2} - \frac{k^3}{6} \frac{\partial^3 u}{\partial t^3} + \frac{k^4}{24} \frac{\partial^4 u}{\partial t^4} - \dots = 0$$

So, consider this approximately equals to 0, so if we expand this term I am expanding minus 2 of course, all of these evaluated at  $x_i, y_j$ , so this term is done then this  $1 - \lambda^2$  square  $i, j$  minus dot, then we have minus  $\lambda^2$  square in this is  $U$  and plus  $h$ . So, we have done earlier, so by now you should be conversant with this technique plus  $U_{i,j-1} - \frac{k}{2} \frac{\partial u}{\partial t} + \dots$ . Now, let us count, so we have this term this term gets cancelled and this term this term gets cancelled then look at there is one  $U_i$  and we have another  $U_i$ . So, we get  $2U_i$ , then we have a minus  $\lambda^2$  square  $U_i$  and another minus  $\lambda^2$  square  $U_i$  so these so this term cancel then which are the term get cancelled So minus  $\lambda^2$  square remain so this so these terms get cancelled.

(Refer Slide Time: 25:47)

$$\begin{aligned} &\Rightarrow k^2 \frac{\partial^2 u}{\partial x^2} + \frac{k^4}{12} \frac{\partial^4 u}{\partial x^4} + \dots \\ &\quad - \lambda^2 \left( \frac{\partial^2 u}{\partial x^2} + \frac{h^4}{12} \frac{\partial^4 u}{\partial x^4} \right) \dots \\ &= k^2 \left( \frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial x^2} \right) + \frac{k^2}{12} \frac{\partial^4 u}{\partial x^4} - \frac{k^2 h^2}{12} \frac{\partial^4 u}{\partial x^4} \\ k^2 \text{ t.e. } &\rightarrow \frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial x^2} + \frac{k^2}{12} \left( \frac{\partial^4 u}{\partial x^4} - h^2 \frac{\partial^4 u}{\partial x^4} \right) \\ &\sim O(k^2 + h^2) \end{aligned}$$

So, if you count it, ultimately we get this minus lambda square etcetera, so this can be written as k square plus k by 12, so we can simplify and ultimately k power minus 2 goes to plus, there is a k square, this is x, 4 x 4 minus h square. So, this is of order because this goes to 0, so the order of the error is this much, so however, let us observe closely the equation which equation this one. So, as I mentioned that I marked, we need two time values at two past time levels j minus 1 and j, so let us see how U h we can proceed with this.

(Refer Slide Time: 28:14)

$$\begin{aligned} u_{i,j+1} &= 2(1-\lambda^2)u_{i,j} + \lambda^2(u_{i-1,j} + u_{i+1,j}) - u_{i,j-1} \quad \text{--- (A)} \\ &\text{in order to start the computation, one need data at} \\ &\text{2 past time levels.} \\ \frac{\partial u}{\partial t}(x,0) = g(x) &\Rightarrow \frac{u_{i,j+1} - u_{i,j-1}}{2k} = g_i + O(k^2) \\ \text{at } (x,0), j=0 &\Rightarrow \frac{u_{i,1} - u_{i,-1}}{2k} = g_i \\ &\Rightarrow u_{i,-1} = u_{i,1} - 2kg_i \quad \text{--- (B)} \\ \text{(A) at } j=0 & \\ u_{i,1} &= 2(1-\lambda^2)u_{i,0} + \lambda^2(u_{i-1,0} + u_{i+1,0}) - u_{i,-1} \\ &= 2(1-\lambda^2)u_{i,0} + \lambda^2(u_{i-1,0} + u_{i+1,0}) - u_{i,1} + 2kg_i \end{aligned}$$

So, I mark is  $U_{i,j} + 1$  is so given this, in order to start the computation, one need data at two past time levels, so this is the remark however consider  $U$  by  $U$  at  $x$  equals to 0 is this is one of our initial condition. This initial velocity is prescribed, so we make use of this  $g_i$ , of course this is of order we call this as second order. now this is at  $x = 0$  we have  $j = 0$ .

So, this implies  $U_{i,1} - 1 = 2k g_i$ , so  $i$  can write this as  $U_{i,1} = U_{i,0} + 2k g_i$ , so this implies these are the values past values so  $U_{i,1} - U_{i,0} = 2k g_i$ , so this is  $b$ . So, when we, let us say we want to compute at  $j = 0$ , so this is at 1, then 0, 0, then we need at minus 1. So, these fictitious values can be eliminated from here, now let us consider  $a$  at  $j = 0$  because that is where we get fictitious values. So, we have  $U_{i,1} = U_{i,0} + 2k g_i$ , so then we can substitute we can substitute this value, so this is so we can 2 times and then we can divide.

(Refer Slide Time: 32:18)

The image shows a slide with handwritten equations for the explicit finite difference scheme. The equations are:

$$u_{i,1} = \frac{\lambda^2}{2} u_{i-1,0} + (1 - \lambda^2) u_{i,0} + \frac{\lambda^2}{2} u_{i+1,0} + k g_i$$

at first time step

$$u_{i,j+1} = \lambda^2 u_{i-1,j} + 2(1 - \lambda^2) u_{i,j} + \lambda^2 u_{i+1,j} - u_{i,j-1}$$

at other time levels

Explicit finite difference scheme.

© CET  
IIT KGP

SPTEL

Ultimately, we get  $U_{i,1} = U_{i,0} + 2k g_i$ , so I did not do anything, so one step I skipped, so this will be 2 times, so everywhere you divide by this, so you get this. Therefore, this is at first time step because you can see at first time step using at zero time step, we can get explicit values. So, this is explicit scheme for the wave equation, so at first time step, we used this for the higher time levels you can see we can compute with this.

So, this is an explicit three level scheme, so let us solve a problem, so as you can see this is very complex. Initially, it looks little difficult task, but when we have displaced the corresponding initial velocity, the fictitious values are removed and hence we got one equation at first time level and then for the remaining we have another equation.

(Refer Slide Time: 35:21)

example

$$u_{xt} = u_{xx}, \quad 0 \leq x \leq 1$$

i.c  $\left\{ \begin{array}{l} u(x,0) = x; \quad u(1,t) = 0; \quad u(0,t) = 0 \\ \frac{\partial u}{\partial t}(x,0) = x = g(x) \end{array} \right.$  b.c

$h = 1/4; \quad \lambda = 1/2$

	0	1/4	1/2	3/4	1
i=0	1	2	3	4	

b.c  $u(0,t) = 0 \Rightarrow u_{0,j} = 0$   
 $u(1,t) = 0 \Rightarrow u_{4,j} = 0$

i.c  $u(x,0) = x \Rightarrow u_{i,0} = x_i$

So, let us consider an example, so an example I have changed the notation and then c is 1, so can understand then so this is of x. So, these are initial conditions and these are boundary conditions, now we need to know h is one fourth lambda is half. So, accordingly we solve for the time levels, now consider the boundary conditions U of 0 t is 0, so this implies U 0 j is 0 U of 1 t is 0, one corresponds to 4, 4 j is 0 and initial condition U of x 0 is x. So, this implies U i 0 is x i and the corresponding discretization I would like to show the next sheet.

(Refer Slide Time: 37:43)

$\frac{\partial u(x,0)}{\partial t} = g(x) = x$   
 $u_{i,1} = \frac{\lambda^2}{2} u_{i-1,0} + (1-\lambda^2) u_{i,0} + \frac{\lambda^2}{2} u_{i+1,0} + \frac{1}{8} x_i$   
 $u_{1,1} = \frac{1}{8} u_{0,0} + \frac{3}{4} u_{1,0} + \frac{1}{8} u_{2,0} + \frac{1}{8} \cdot \frac{1}{4}$   
 $= \frac{1}{8} \cdot 0 + \frac{3}{4} \cdot \frac{1}{4} + \frac{1}{8} \cdot \frac{1}{2} + \frac{1}{8} \cdot \frac{1}{4} = \frac{1}{16} \cdot 9$   
 $u_{2,1} = \frac{1}{8} u_{1,0} + \frac{3}{4} u_{2,0} + \frac{1}{8} u_{3,0} + \frac{1}{8} \cdot \frac{1}{2}$   
 $= \frac{1}{8} \cdot \frac{1}{4} + \frac{3}{4} \cdot \frac{1}{2} + \frac{1}{8} \cdot \frac{3}{4} + \frac{1}{8} \cdot \frac{1}{2}$   
 $= \frac{1}{8} \cdot 9$

$u_{i,0} = x_i$   
 $j=2$   
 $j=1$   
 $j=0$

So,  $\frac{\partial u}{\partial t}$  at  $x=0$  is  $g(x)$  which is equal to  $x$  in our case and from the previous discretization we have obtained you can see. So, we make use of it, so  $u_{i,1}$  equals  $\frac{\lambda^2}{2} u_{i-1,0} + (1-\lambda^2) u_{i,0} + \frac{\lambda^2}{2} u_{i+1,0} + \frac{1}{8} x_i$  and in this case  $K$  becomes  $\frac{1}{8}$ . So, we have, now let us compute the values at each nodal point, so we have this 0, one fourth, half, three fourth, 1. So,  $u_{1,1}$  equals  $\frac{\lambda^2}{2} u_{0,0} + (1-\lambda^2) u_{1,0} + \frac{\lambda^2}{2} u_{2,0} + \frac{1}{8} x_1$ , so this becomes  $\frac{1}{8} u_{0,0} + \frac{3}{4} u_{1,0} + \frac{1}{8} u_{2,0} + \frac{1}{8} \cdot \frac{1}{4}$ .

So, this will be  $\frac{1}{8} u_{0,0} + \frac{3}{4} u_{1,0} + \frac{1}{8} u_{2,0} + \frac{1}{8} \cdot \frac{1}{4}$ , so  $x_1$  is this, so  $\frac{1}{8} \cdot 0 + \frac{3}{4} \cdot \frac{1}{4} + \frac{1}{8} \cdot \frac{1}{2} + \frac{1}{8} \cdot \frac{1}{4}$ , so this can be obtained  $u_{1,1}$ , so this is  $0 + \frac{3}{4} \cdot \frac{1}{4} + \frac{1}{8} \cdot \frac{1}{2} + \frac{1}{8} \cdot \frac{1}{4}$ , so we have  $u_{i,0}$  is  $x_i$ , the remaining are 0. So, this is one fourth, this is half, so this is calculated, please check it, so then  $u_{2,1}$ , so  $u_{2,1}$  means the grid is like this. It is asking, so this is  $j=0$ ,  $j=1$ ,  $j=2$ . So, in our case, the method asked  $j=0$  and  $j=1$ , so in order to compute  $j=1$ , we made use of this equation that is what we are doing at each grid point. Using  $j=0$ , we are computing at  $j=1$ , so that we use the other formula and compute, so  $u_{2,1}$  is  $\frac{1}{8} u_{1,0} + \frac{3}{4} u_{2,0} + \frac{1}{8} u_{3,0} + \frac{1}{8} x_2$ , so this will be  $\frac{1}{8} u_{1,0} + \frac{3}{4} u_{2,0} + \frac{1}{8} u_{3,0} + \frac{1}{8} \cdot \frac{1}{2}$  that is  $x_2$  that is  $\frac{1}{4}$  is half, three by four, so this is obtained as.

(Refer Slide Time: 42:52)

$$u_{3,1} = \frac{1}{8} \cdot u_{2,0} + \frac{3}{4} u_{2,1} + \frac{1}{8} u_{2,2} + \frac{1}{8} \cdot \frac{3}{4}$$

$$= \frac{1}{8} \cdot \frac{1}{2} + \frac{3}{4} \cdot \frac{3}{4} + \frac{1}{8} \cdot 1 + \frac{1}{8} \cdot \frac{3}{4} = \frac{1}{8} \cdot \frac{27}{4}$$

at higher levels

$$u_{i,j+1} = \lambda^2 u_{i+1,j} + 2(1-\lambda^2) u_{i,j} + \lambda^2 u_{i-1,j} - u_{i,j-1}$$

j=1

$$u_{i,2} = \frac{1}{4} u_{i+1,1} + \frac{3}{2} u_{i,1} + \frac{1}{4} u_{i-1,1} - u_{i,0}$$

i=1

$$u_{1,2} = \frac{1}{4} u_{0,1} + \frac{3}{2} u_{1,1} + \frac{1}{4} u_{2,1} - u_{1,0}$$

$$= \frac{1}{4}(0) + \frac{3}{2} \cdot \frac{1}{16} + \frac{1}{4} \cdot \frac{9}{8} - \frac{1}{4} = \frac{5}{16}$$

Similarly, we obtain  $U_{3,1}$  we obtain  $\frac{1}{8} U_{2,0} + \frac{3}{4} U_{2,1} + \frac{1}{8} U_{2,2} + \frac{1}{8} \cdot \frac{3}{4}$ , so this is  $\frac{1}{8} \cdot \frac{1}{2} + \frac{3}{4} \cdot \frac{3}{4} + \frac{1}{8} \cdot 1 + \frac{1}{8} \cdot \frac{3}{4}$ , so that is  $\frac{1}{8} \cdot \frac{27}{4}$ , as the second. So, this is  $3$  i equal to  $3$ , so this is  $\frac{27}{32}$ , so this is  $1$  plus, so this may be computed. Now, we have obtained all the values required to compute at other time levels, these are the first time level, now we proceed at higher levels, so at higher levels, so let us consider  $j$  equals to  $1$ . So, this is at second level at all grid points now we can use this and compute at each, so for example, you want, this must be  $i$  in general case, I am sorry this is  $i$  plus  $1$  i. So, in this is in this case, these values are substituted, so just now we have computed  $U_{1,1}$ , so these values will be used, so you verify so this is the value at this point.

(Refer Slide Time: 46:27)

Handwritten mathematical derivation on a blue background. At the top right, there is a small logo with the text "© CET I.I.T. KGP". At the bottom left, there is a circular logo with a star and the text "MPTEL".

$$\begin{aligned}
 \underline{i=2} \quad u_{2,2} &= \frac{1}{4} u_{1,1} + \frac{3}{2} u_{2,1} + \frac{1}{4} u_{3,1} - u_{2,0} \\
 &= \frac{1}{4} \cdot \frac{1}{16} \cdot 9 + \frac{3}{2} \cdot \frac{1}{8} \cdot 9 + \frac{1}{4} \cdot \frac{1}{8} \cdot \frac{27}{4} - \frac{1}{2} = 5/8.
 \end{aligned}$$

$$\underline{i=3} \quad u_{3,2} = \dots$$

Then,  $i$  equals 2, so this will be 3 1, we have calculated earlier, so this we get, similarly we can compute, so this is very straight forward once you get the values at first time level. So, then higher time levels can be obtained by the final differences scheme which is more general, so it is a combination of two expressions, first one is at first time level then the rest is for any general  $j$ . So, with one can match fast and compute at higher levels, so this is very explicit method, now let us review let us see under what situations we get implicit method.

Implicit Method

Consider 
$$u_{i,j+1} = 2(1-\lambda^2)u_{i,j} + \lambda^2(u_{i+1,j} + u_{i-1,j}) - u_{i,j-1}$$

$$= \lambda^2(u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) + 2u_{i,j} - u_{i,j-1}$$
 replace  $u_{i,j}$  on RHS by  $u_{i,j} = \frac{1}{2}(u_{i,j+1} + u_{i,j-1})$  "data at  $j$ th level would be replaced"

$$u_{i,j+1} = \lambda^2 \left\{ \frac{u_{i-1,j+1} + u_{i+1,j-1}}{2} - 2 \frac{u_{i,j+1} + u_{i,j-1}}{2} + \frac{u_{i+1,j+1} + u_{i-1,j-1}}{2} \right\} + 2 \frac{u_{i,j+1} + u_{i,j-1}}{2} - u_{i,j-1}$$

So, consider  $U_{i,j+1}$ , so this is a three level explicit method which we have derived, now this I would like to just put it in a slightly different form, so the same one. Now, what we are going to do is replace  $U_{i,j}$  on r h s by, so we want to bring in more time levels, so then only this becomes implicit. So, what we are trying to attempt, we are trying to attempt implicit method, so all that we are doing is introduce more time levels. So, let us see what happens, so here when I say r h s  $U_{i,j}$ , that means data at  $j$  th level would be replaced.

Now, this is at  $j$  th level, so we manipulate the index for  $i,j$  this is a rule, so correspondingly for  $i$  minus 1  $j$ . So, this remain, then we have  $j+1$   $j-1$  by 2, then we have 2 times  $U_{i,j}$  by 2, then we have this is lambda square, then we have plus 2 by 2 minus. So, this is not replaced because this is containing  $j-1$  time level, so what did we do we have replaced all the data point from right hand side which are at  $j$ th level by average of  $j+1$  and  $j-1$ . So, you can see we are expanding the scope, so we expect more accuracy, so this is general idea.

So, accordingly we have manipulated the corresponding index notation for the  $U_{i,j}$ , this one for  $U_{i-1,j}$   $i-1$   $j+1$   $i-1$   $j-1$  accordingly. Now, we can simplify, so we can simplify and see you have various terms for example, this is  $U_{i-1,j+1}$  and this is  $i+1$   $j+1$ . Some terms are expected to be cancelled, let us see  $U_{i,j+1}$   $U_{i,j+1}$ , so we do not have any.

The image shows a handwritten derivation on a blue background. The equations are:

$$\Rightarrow U_{i-1,j+1} - 2U_{i,j+1} + U_{i+1,j+1}$$

$$= -U_{i-1,j-1} + 2U_{i,j-1} - U_{i+1,j-1}$$

To the right of the second equation, the text "Implicit scheme" is written. In the top right corner, there is a small logo with the text "© CET I.T. KGP". In the bottom left corner, there is a circular logo with the text "NPTEL" below it.

So, this reduces to  $U_{i,j+1}$  plus 1, so if we adjust these, this is  $\lambda^2$  here. So, we have replaced, then we have to rearrange these terms, so then when we rearrange these terms, we get implicit scheme.

(Refer Slide Time: 54:20)

Handwritten derivation on a blue background:

$\Rightarrow u_{i-1,j+1} - 2u_{i,j+1} + u_{i+1,j+1}$

Implicit Method

Consider  $u_{i,j+1} = 2(1-\lambda^2)u_{i,j} + \lambda^2(u_{i,j} + u_{i+1,j}) - u_{i,j-1}$

$= \lambda^2(u_{i,j} - 2u_{i,j} + u_{i+1,j}) + 2u_{i,j} - u_{i,j-1}$

replace  $u_{i,j}$  on RHS by  $u_{i,j} \approx \frac{1}{2}(u_{i,j+1} + u_{i,j-1})$  "data at  $j^{\text{th}}$  level would be replaced"

$u_{i,j+1} = \lambda^2 \left\{ \frac{u_{i-1,j+1} + u_{i+1,j+1}}{2} - \cancel{u_{i,j+1}} + \frac{u_{i,j+1} + u_{i,j-1}}{2} \right. \\ \left. + \frac{u_{i+1,j+1} + u_{i+1,j-1}}{2} \right\} + 2 \frac{u_{i,j+1} + u_{i,j-1}}{2} - u_{i,j-1}$

$u_{i,j+1}(\lambda^2 + 1)$   
 $u_{i,j-1}(-\lambda^2 + 1)$

So, we can see how this would come up, so we have variety of terms  $i$  minus 1  $j$  plus 1, so this term then we have  $i$   $j$  plus 1 two times. So, we have two get cancelled, so we have to do some exercise here, so two get cancelled, then two get cancelled. So, we have  $U_{i,j}$  plus 1, so let us collect the coefficients  $U_{i,j}$  plus 1, we have  $\lambda^2$  here, then plus 1, then  $U_{i,j}$  minus 1, so we have, sorry minus  $\lambda^2$  because there is a minus sign.

So, similarly here minus  $\lambda^2$  and plus 1, so these terms are done, then  $U_{i-1,j}$  plus 1  $U_{i,j}$  plus 1  $U_{i,j}$  minus 1 here. So, this I will come back to you with on the  $\lambda^2$ , then similarly we have other terms, so these four terms are taken care. So,  $U_{i-1,j}$  minus 1  $j$  minus 1 so you can this is the term then  $U_{i,j}$  minus 1, so these are the terms, then similarly,  $i$  plus 1  $j$  plus 1  $i$  plus 1  $j$  minus 1, so  $i$  plus 1  $j$  plus 1  $i$  plus 1  $j$  minus 1.

(Refer Slide Time: 56:56)

$$\Rightarrow u_{i-1,j+1} - 2u_{ij+1} + u_{i+1,j+1}$$

$$= -u_{i,j-1} + 2u_{ij} - u_{i,j+1}$$

Implicit scheme  
Special value of  $\lambda$

Implicit Method

Consider 
$$u_{i,j+1} = 2(1-\lambda^2)u_{ij} + \lambda^2(u_{i,j} + u_{i+1,j}) - u_{i,j-1}$$

$$= \lambda^2(u_{i,j} - 2u_{ij} + u_{i+1,j}) + 2u_{ij} - u_{i,j-1}$$

replace  $u_{ij}$  on RHS by  $u_{ij} \approx \frac{1}{2}(u_{i,j+1} + u_{i,j-1})$  "data at  $j$ th level would be replaced"

$$u_{i,j+1} = \lambda^2 \left\{ \frac{u_{i-1,j+1} + u_{i+1,j-1}}{2} - \cancel{u_{i,j+1}} + \cancel{u_{i,j-1}} \right\}$$

So, this is for a special case, so this is a special value of lambda, but we can get more general formula from here that involves lambda. So, this gives implicit method and then you can see left hand side, you have values corresponding to  $j$  plus 1 and right hand side you have values corresponding to  $j$  th level. Hence, you get a system of equations, so we will pay more attention to the implicit method in the coming lecture, until then bye.
