**Lecture - 2**  
**Simple Linear Regression**

Hi, this is my second lecture in module one and on simple linear regression. In the first lecture, we have introduced simple linear regression model and they have learnt how to estimate the regression coefficients using least square technique.

(Refer Slide Time: 01:25)

Here is the content of today's lecture first will give one example on simple linear regression. And then we talk about useful properties of least square fit and then the statistical property of least square estimator.

(Refer Slide Time: 01:53)

### Example: Simple Linear Regression

You're a marketing analyst for Disney Toys. You gather the following data:

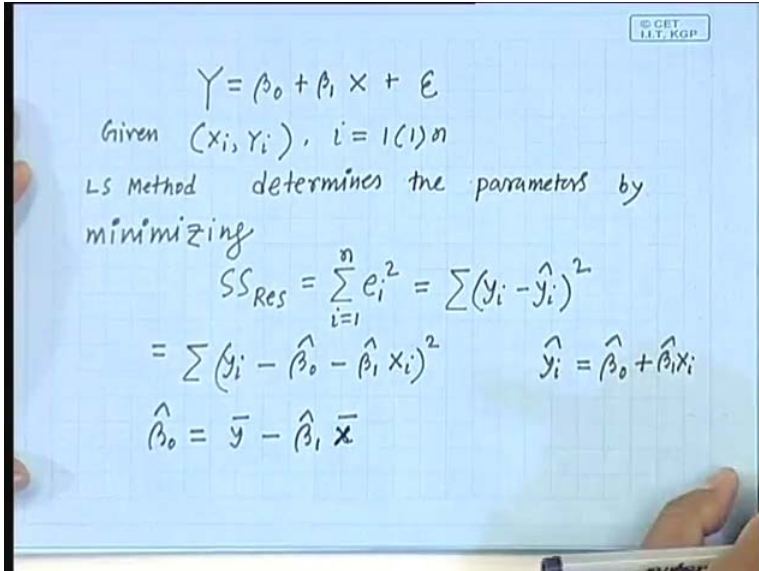

Ad \$	Sales (Units)
1	1
2	1
3	2
4	2
5	4

• What is the relationship between sales & advertising?

Well let me just recall the simple linear regression model. The general form of simple linear regression model is a Y equal to beta naught plus beta 1 X plus epsilon.

(Refer Slide Time: 02:08)

© CET  
IIT, KGP

$$Y = \beta_0 + \beta_1 X + \epsilon$$

Given  $(X_i, Y_i)$ ,  $i = 1(1)n$

LS Method determines the parameters by minimizing

$$SS_{Res} = \sum_{i=1}^n e_i^2 = \sum (y_i - \hat{y}_i)^2$$
$$= \sum (y_i - \hat{\beta}_0 - \hat{\beta}_1 X_i)^2 \quad \hat{y}_i = \hat{\beta}_0 + \hat{\beta}_1 X_i$$
$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x}$$

Where Y is the response variable X is the regressor variable and epsilon is the error term and beta naught is intercept and beta 1 is slope and we call beta naught into beta 1 there regression coefficients. Now, given a set of observations say X i Y i for i equal to 1 to n we learned how to estimate the regression coefficients beta naught and beta 1 using least square technique. So, least squares method determines the parameters means the

regression coefficients beta naught and beta 1 by minimizing residual sum of squares SS residual. Which is equal to  $e_i^2$  equal to 1 to n, which is basically equal to the difference between the observed response value and the estimated response value  $y_i$  hat.

So, this is the residual and  $y_i$  hat this is  $y_i$  minus  $t_i$  hat is the is equal to beta naught hat plus beta 1 hat X. So, this is beta naught hat minus beta 1 hat X i whole square. Because the fitted equation is  $y_i$  hat equal to beta naught hat plus beta 1 hat X i. So, we learned that beta naught I mean this SS residual or residual sum of squares is minimum. When beta naught hat is equal to  $\bar{Y}$  minus beta 1 hat X bar.

(Refer Slide Time: 05:53)

LS Method determines the parameters by minimizing

$$SS_{Res} = \sum_{i=1}^n e_i^2 = \sum (y_i - \hat{y}_i)^2$$

$$= \sum (y_i - \hat{\beta}_0 - \hat{\beta}_1 x_i)^2 \quad \hat{y}_i = \hat{\beta}_0 + \hat{\beta}_1 x_i$$

$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x}$$

$$\hat{\beta}_1 = \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sum (x_i - \bar{x})^2} = \frac{S_{xy}}{S_{xx}} = \frac{\sum x_i y_i - n \bar{x} \bar{y}}{\sum x_i^2 - n \bar{x}^2}$$

And beta 1 hat is equal to summation  $x_i$  minus  $x$  bar  $y_i$  minus  $y$  bar by summation  $x_i$  minus  $x$  bar whole square. Well this quantity is also denoted by the symbol  $S_{xy}$  by  $S_{xx}$  and this one can also be written in the form summation  $x_i y_i$  minus  $x$  bar  $y$  bar  $n$  times by summation  $x_i$  square minus  $n$  into  $x$  bar square. This is not difficult to observe just a simple algebra shows that this quantity is equal to this quantity. So, let us move to the disney toy example this is the cost on advertising and this is the sales amount, so these are the  $x_i$  values and this are the  $y_i$  values. And even to fit a straight-line model to this data this table shows.

(Refer Slide Time: 08:02)

$X_i$	$Y_i$	$X_i^2$	$Y_i^2$	$X_i Y_i$
1	1	1	1	1
2	1	4	1	2
3	2	9	4	6
4	2	16	4	8
5	4	25	16	20
15	10	55	26	37

Summation  $X_i$  is equal to 15 summation,  $Y_i$  is equal to 10 summation,  $X_i$  square is equal to 55 summation,  $Y_i$  square is equal to 26 and summation  $X_i Y_i$  is equal to 37.

(Refer Slide Time: 08:31)

**Parameter Estimation Solution**

$$\hat{\beta}_1 = \frac{\sum_{i=1}^n X_i Y_i - n \bar{X} \bar{Y}}{\sum_{i=1}^n X_i^2 - n \bar{X}^2} = \frac{37 - 5 \times 3 \times 2}{55 - 5 \times 3^2} = 0.70$$
$$\hat{\beta}_0 = \bar{Y} - \hat{\beta}_1 \bar{X} = 2 - (0.70)(3) = -0.10$$

**Fitted Equation:**  $\hat{Y} = -0.10 + 0.7X$

And then we can compute the value of beta 1 hat. So, beta 1 hat is equal to summation  $X_i Y_i$  minus  $n$  times  $\bar{X}$  into  $\bar{Y}$  by summation  $X_i$  square minus  $n$  times  $\bar{X}$  square which is equal to 0.7. And similarly beta naught hat is equal to  $\bar{Y}$  minus beta 1 hat  $\bar{X}$  which is equal to minus 0.1. Well so the fitted equation is  $\hat{Y}$  equal to beta naught which is equal to minus 0.1 plus 0.7 into  $X$ . So, this is the fitted equation for the

given observations, now what is the interpretation of this regression coefficient beta 1. So, it says that that the expected value of the response variable or.

(Refer Slide Time: 10:03)

**Coefficient Interpretation**

**Slope ( $\hat{\beta}_1$ )**

**Sales volume (Y) is expected to increase by .7 units for each \$1 increase in Advertising (X)**

The expected sales amount is increased by 0.7 units for each 1 dollar increase in advertising and the interpretation of the coefficient beta naught hat is that.

(Refer Slide Time: 10:17)

**Coefficient Interpretation**

**Y-Intercept ( $\hat{\beta}_0$ )**

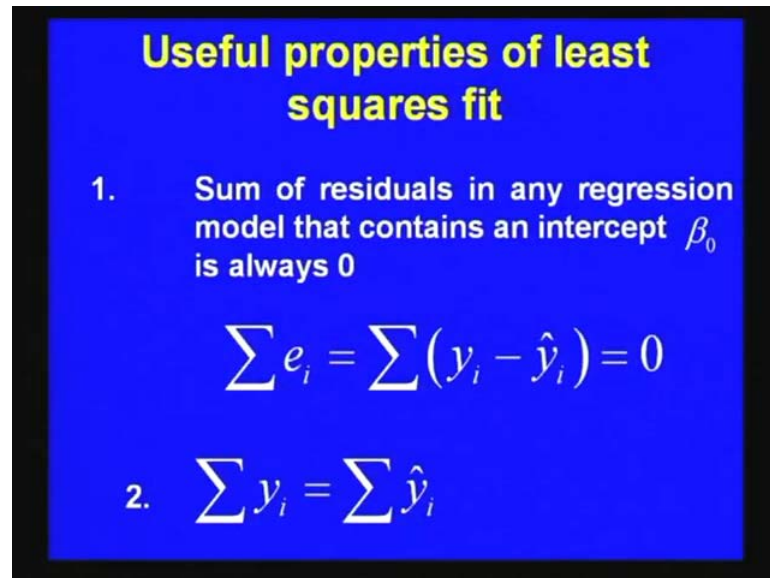

**Average value of Sales volume (Y) is – .10 units when advertising (X) is 0**

- **Difficult to Explain to Marketing Manager**
- **Expect some sales without Advertising**

What is the average sales amount when X is equal to 0 beta naught is equal to Y hat, when x is equal to 0. So, beta naught beta naught hat this basically gives some idea about the average value of sales amount when the advertising cost is equal to 0. So I mean its

very difficult explain why it is so because see we can expect some sales amount without advertising also. But here it is negative anyway, so the beta naught hat is the average sales volume which is equal to minus 0.1 when the advertising is equal to 0.

(Refer Slide Time: 11:24)

**Useful properties of least squares fit**

1. Sum of residuals in any regression model that contains an intercept  $\beta_0$  is always 0
$$\sum e_i = \sum (y_i - \hat{y}_i) = 0$$
2. 
$$\sum y_i = \sum \hat{y}_i$$

Well next we move to the useful properties of the least square fit. It says that we know what is residual is  $e_i$  is the difference between the observed response value and the predicted or the estimated response value. So, it says that the sum of residuals in any regression model that contains a intercept  $\beta_0$  is always 0. I am going to prove this one, so this summation  $e_i$  is equal to 0.

And the second property says that the sum of the observed value is equal to the sum of the fitted values  $\hat{y}_i$ . So I mean this second property is consequence of the first property it is obtained from this one only. Let me prove the first property which says that the some of residuals in any regression model that contains an intercept  $\beta_0$  is always equal to 0. So, what it to do is that we have to recall the.

(Refer Slide Time: 13:00)

LS Method  $\beta_0$  &  $\beta_1$   
minimizing  $SS_{Res} = \sum e_i^2 = \sum (y_i - \hat{y}_i)^2$   
 $= \sum (y_i - \hat{\beta}_0 - \hat{\beta}_1 x_i)^2$   
Normal equations  
①  $-2 \sum (y_i - \hat{\beta}_0 - \hat{\beta}_1 x_i) = 0 \Rightarrow \sum e_i = 0$   
②  $\sum e_i = \sum (y_i - \hat{y}_i) = 0$   
 $\Rightarrow \sum y_i = \sum \hat{y}_i$

L S method least squares method least squares method determines the parameter beta naught and beta 1 by minimizing by minimizing SS residual that this residual sum of square. Which is equal to summation e i square and this is basically equal to summation y i minus y i hat square. And this is equal to summation y i minus beta naught hat minus beta 1 hat x i square well.

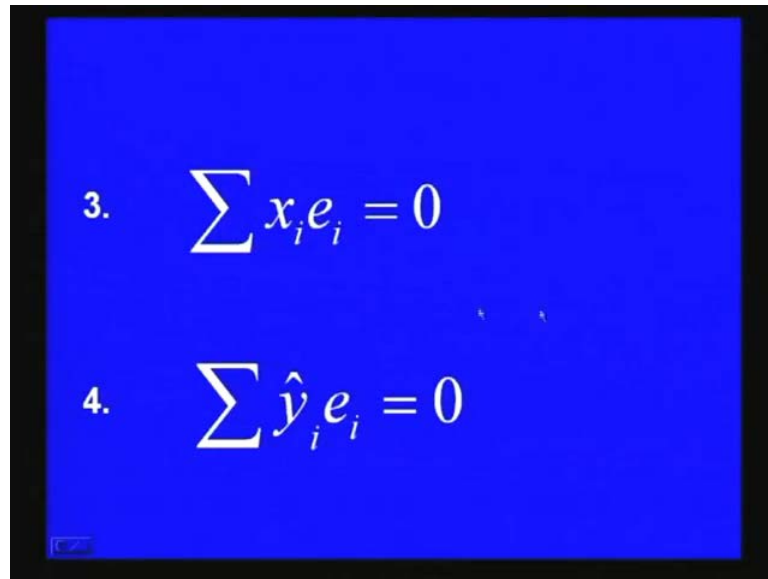

So, least squares method or L S method determines the parameter beta naught hat and beta 1 hat by minimizing this quantity. So, what we do is that we differentiate the residual sum of square with respect to beta naught hat and we equate that with 0. We did the first normally equations the normally equations differentiate SS residual with beta naught hat that gives one normally equation.

And again we differentiate residual sum of squares with respect to beta 1 hat that gives another normally equation the first normally equation. We differentiate SS residual with respect to 0, sorry with respect to beta naught hat that gives summation y i minus beta naught hat minus beta 1 hat x i 2 times of this and one negative sign here. So, and we equate this 2 equal to 0 this is the first normally equation and which is nothing but see.

This is nothing but y i minus y i hat, so this one is nothing but summation e i equal to 0. To the first normally equation says that the sum of the residual is equal to 0. And this residual sum of residual e i is nothing but summation. So, this is the first property the second property says that well this is residual some of residual is equal to y i minus y i

that this is the residual  $e_i$ . And we know this is equal to 0 from the first property, which implies that  $\sum y_i$  is equal to  $\sum \hat{y}_i$ . So, this one is the consequence of the previous property or the first property it says that the sum of observed values equal to is equal to the sum of the fitted value well. So, next will move to the third property.

(Refer Slide Time: 16:52)

3.  $\sum x_i e_i = 0$

4.  $\sum \hat{y}_i e_i = 0$

It says that  $\sum x_i e_i$  equal to 0, that means sum of residuals waited by the corresponding value of the regressor variable is equal to 0. So, sum of residual  $e_i$  waited by the corresponding value of the regression variable this is the value of the  $i$ th regression variable this is equal to 0. And the fourth property says that  $\sum \hat{y}_i e_i$  is equal to 0. That means the sum of residuals waited by the corresponding fitted value of the response variable is equal to 0, well let me prove this two properties.

Property three and property four well by differentiating this residual sum of square with respect to  $\beta_1$ . We got this normally equation this is the first normally equation, now again we differentiate this normally equation sorry this some of residual with respect to  $\beta_1$ .

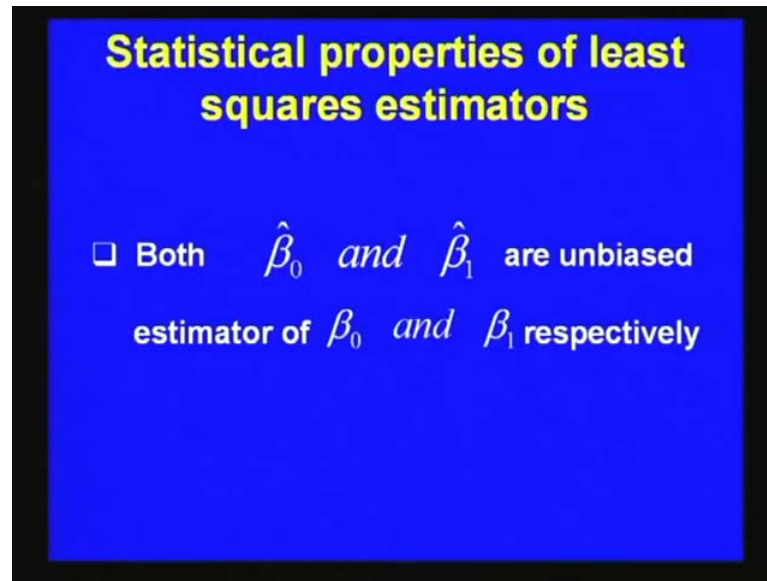

(Refer Slide Time: 18:28)

$$\begin{aligned} -2 \sum (y_i - \hat{\beta}_0 - \hat{\beta}_1 x_i) x_i &= 0 \\ \Rightarrow \sum (y_i - \hat{y}_i) x_i &= 0 \\ \Rightarrow \sum e_i x_i &= 0 \\ \textcircled{4} \quad \sum e_i \hat{y}_i &= 0 \quad \boxed{\sum e_i y_i \neq 0} \\ \Rightarrow \sum e_i (\hat{\beta}_0 + \hat{\beta}_1 x_i) &= 0 \\ &= \hat{\beta}_0 \sum e_i + \hat{\beta}_1 \sum e_i x_i \\ &= \hat{\beta}_0 \cdot 0 + \hat{\beta}_1 \cdot 0 = 0 \end{aligned}$$

And that gives summation  $y_i$  minus  $\beta_0$  hat minus  $\beta_1$  hat  $x_i$  and we are differentiating with respect to  $\beta_1$  hat. So, this quantity will be multiplied by minus 2 into  $x_i$ , so minus 2 into  $x_i$  which is equal to 0. This is the second normal equation and this one is nothing but summation  $y_i$ . And this part is  $y_i$  hat into  $x_i$  equal to 0, which implies summation  $e_i x_i$  equal to 0 which is the third property. Now, the fourth property is summation  $e_i y_i$  hat this is equal to 0. But, summation  $e_i y_i$  is not equal to 0 you should note that how to prove that summation  $e_i y_i$  hat equal to 0.

This is again consequence of the first property and the third property well this can be written as summation  $e_i$  what is a  $y_i$  hat  $y_i$  hat is equal to  $\beta_0$  hat plus  $\beta_1$  hat  $x_i$  which is equal to 0. Which is equal to which is equal to summation  $\beta_0$  hat  $e_i$  plus  $\beta_1$  hat summation  $e_i x_i$ . Now, see summation  $e_i$  from the first property this is equal to 0. So, this is equal to 0 plus the third property says that summation  $e_i x_i$  equal to 0. So, this is basically  $\beta_0$  hat into 0 plus  $\beta_1$  hat into 0. So, this is equal to 0, so you prove that summation  $e_i y_i$  hat equal to 0. Ok, so these are the some properties of least square fit and will be using them in the future.

(Refer Slide Time: 21:30)

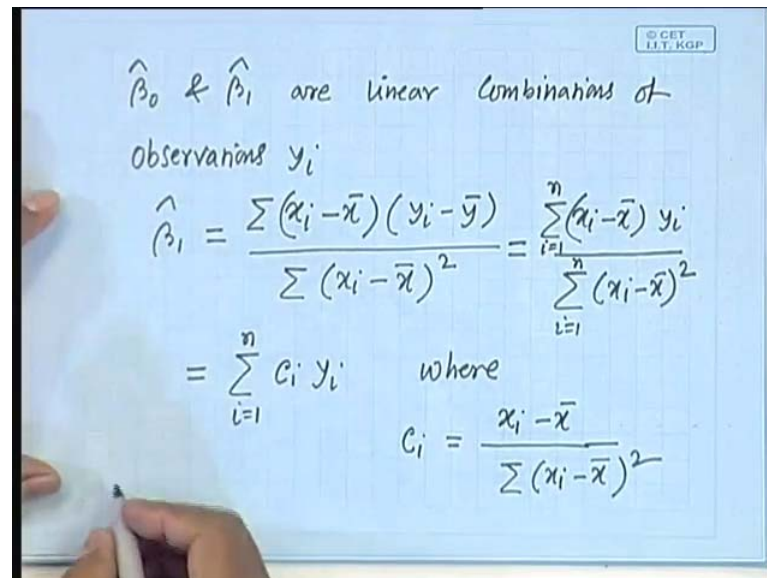

**Statistical properties of least squares estimators**

- Both  $\hat{\beta}_0$  and  $\hat{\beta}_1$  are unbiased estimator of  $\beta_0$  and  $\beta_1$  respectively

Next move to the statistical properties of least square estimators. So, we have estimated the regression coefficient beta naught and beta 1 using least square estimators. And we are going to prove that both beta naught hat and beta 1 hat are unbiased estimator of beta naught an beta 1 respectively well let me prove that.

(Refer Slide Time: 22:20)

$\hat{\beta}_0$  &  $\hat{\beta}_1$  are linear combinations of observations  $y_i$

$$\hat{\beta}_1 = \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sum (x_i - \bar{x})^2} = \frac{\sum_{i=1}^n (x_i - \bar{x}) y_i}{\sum_{i=1}^n (x_i - \bar{x})^2}$$
$$= \sum_{i=1}^n c_i y_i \quad \text{where} \quad c_i = \frac{x_i - \bar{x}}{\sum (x_i - \bar{x})^2}$$

First I will prove that beta naught hat and beta 1 hat are linear combinations of observations  $y_i$ , that means we want to say that they are linear estimator. Ok for example, considered beta 1 hat , so what is beta 1 hat beta 1 hat is equal to summation  $x_i$

minus  $\bar{x}$  into  $y_i - \bar{y}$  by summation  $(x_i - \bar{x})^2$ . Now, I said that this is linear combination of the response variables  $y_i$  s other observation  $y_i$  s. This can be written as this can be written as summation  $(x_i - \bar{x}) y_i$  only by summation  $(x_i - \bar{x})^2$  this is it i mean this two quantity are same.

One can very easily prove that summation  $(x_i - \bar{x}) \bar{y}$  that quantity is equal to 0. This is not difficult to prove that now this is from  $i$  equal to 1 to  $n$  and  $i$  equal to 1 to  $n$ . Now, this can be written as summation  $C_i y_i$  were  $C_i$  is equal to here  $i$  equal to 1 to  $n$  were  $C_i$  is equal to  $(x_i - \bar{x})$  by summation  $(x_i - \bar{x})^2$ . So, I prove that  $\hat{\beta}_1$  is a linear combination of the observations  $y_i$ . Similarly, one can prove that  $\hat{\beta}_0$  is also easily what is  $\hat{\beta}_0$  what is  $\hat{\beta}_0$ .

(Refer Slide Time: 25:38)

$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x}$$

$$= \frac{1}{n} \sum_{i=1}^n y_i - \hat{\beta}_1 \bar{x}$$

$\hat{\beta}_0$  is equal to  $\bar{y} - \hat{\beta}_1 \bar{x}$ . So, this is also a linear combination of the observation. Because this is nothing but this is nothing but summation  $y_i$  from  $i$  equal to 1 to  $n$  and minus  $\hat{\beta}_1 \bar{x}$ . We already prove that  $\hat{\beta}_1$  is a linear combination of the observation  $y_i$  and the first term is also a linear combination of  $y_i$ . So, the whole thing is a linear combinations of the observations  $y_i$ . So, this just prove that the estimator we got they are linear estimator they are linear in  $y_i$  next let me prove that the estimator  $\hat{\beta}_0$  and  $\hat{\beta}_1$  they are.

(Refer Slide Time: 26:55)

The whiteboard shows the following derivation:

$$E(\hat{\beta}_1) = \beta_1 \quad \left| \quad \begin{aligned} y_i &= \beta_0 + \beta_1 x_i + \epsilon_i \\ \bar{y} &= \frac{1}{n} \sum_{i=1}^n y_i = \beta_0 + \beta_1 \bar{x} + \bar{\epsilon} \\ \bar{x} &= \frac{1}{n} \sum_{i=1}^n x_i, \quad \bar{\epsilon} = \frac{1}{n} \sum_{i=1}^n \epsilon_i \end{aligned} \right.$$

$$E(y_i - \bar{y}) = \beta_1(x_i - \bar{x}) + E(\epsilon_i - \bar{\epsilon})$$

$$= \beta_1(x_i - \bar{x}) \quad \epsilon_i \sim N(0, \sigma^2)$$

$$E(\hat{\beta}_1) = E\left[ \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sum (x_i - \bar{x})^2} \right] = \frac{\sum (x_i - \bar{x}) E(y_i - \bar{y})}{\sum (x_i - \bar{x})^2}$$

Unbiased estimator that is we are going to prove that expectation of beta 1 hat is equal to beta 1. So, if this is true then we call beta 1 is an unbiased estimator. Well let me start from here the simple linear regression model is  $y_i$  is equal to beta naught plus beta 1  $x_i$  plus epsilon  $i$ . Now,  $y$  bar  $y$  bar which is equal to summation  $y_i$   $i$  equal to 1 to  $n$ . This is equal to beta naught plus beta 1  $x$  bar and epsilon  $i$  will be replaced by epsilon bar. So, were  $x$  bar were  $x$  bar is of course, equal to summation  $x_i$   $i$  1 to  $n$  and epsilon bar is also equal to summation epsilon  $y$  summation epsilon  $y$  1 to  $n$ .

Then from here  $y_i$  minus  $y$  bar is equal to  $y_i$  minus  $y$  bar is equal to beta 1 into  $x_i$  minus  $x$  bar plus epsilon  $i$  minus epsilon bar. So, the expected value of the expected value of  $y_i$  minus  $y$  bar is equal to. See one thing you should observe that you should always remember that  $y$  is a random variable. The response variable  $y$  is a random variable, but  $x$  is not a random variable it is its controlled variable. So, for given  $i$  this is just a constant, so expected value of  $y_i$  minus  $y$  bar is equal to beta 1  $x_i$  minus  $x$  bar plus expectation of epsilon  $i$  minus epsilon bar.

Now, epsilon  $i$  is the random error which follows which is a random variable and this follows we are assumed that epsilon  $i$  follows normal 0 sigma square. So, the expected value of  $e_i$  is equal to 0 and similarly the expected value of epsilon bar is also equal to 0. The expected value of  $y_i$  minus  $y$  bar this term is going to be 0 is equal to beta 1 into  $x_i$  minus  $x$  bar. Now, our aim is to prove that beta 1 hat is an unbiased estimated of beta 1,

so expectation of beta 1 hat is equal to expectation of what is beta 1 hat beta 1 hat is equal to summation x i minus x bar y i minus y bar by summation x i minus x bar whole square. So, this one is nothing but summation x i minus x bar into expectation of y i minus y bar by summation x i minus x bar whole square.

(Refer Slide Time: 32:37)

Handwritten mathematical derivation on a whiteboard:

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i, \quad \bar{\epsilon} = \frac{1}{n} \sum_{i=1}^n \epsilon_i$$

$$E(y_i - \bar{y}) = \beta_1 (x_i - \bar{x}) + E(\epsilon_i - \bar{\epsilon})$$

$$= \beta_1 (x_i - \bar{x}) \quad \epsilon_i \sim N(0, \sigma^2)$$

$$E(\hat{\beta}_1) = E\left[ \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sum (x_i - \bar{x})^2} \right] = \frac{\sum (x_i - \bar{x}) E(y_i - \bar{y})}{\sum (x_i - \bar{x})^2}$$

Now note that we proved that expectation of y i minus y bar is equal to beta 1 into x i minus x bar, so expectation of beta 1 hat is equal to summation x i minus x bar.

(Refer Slide Time: 33:04)

Handwritten mathematical derivation on a whiteboard:

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i, \quad \bar{\epsilon} = \frac{1}{n} \sum_{i=1}^n \epsilon_i$$

$$E(y_i - \bar{y}) = \beta_1 (x_i - \bar{x}) + E(\epsilon_i - \bar{\epsilon})$$

$$= \beta_1 (x_i - \bar{x}) \quad \epsilon_i \sim N(0, \sigma^2)$$

$$E(\hat{\beta}_1) = E\left[ \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sum (x_i - \bar{x})^2} \right] = \frac{\sum (x_i - \bar{x}) E(y_i - \bar{y})}{\sum (x_i - \bar{x})^2}$$

$$E(\hat{\beta}_1) = \frac{\beta_1 \sum (x_i - \bar{x})(x_i - \bar{x})}{\sum (x_i - \bar{x})^2} = \beta_1$$

And this quantity is equal to  $\beta_1 \sum (x_i - \bar{x})^2$ . So, this is nothing but  $\beta_1$  only because this one is nothing but  $\sum (x_i - \bar{x})^2$ . So, he proved that  $\beta_1$  is an unbiased estimated of  $\beta_1$  similarly, next we prove that  $\hat{\beta}_0$  is an unbiased estimated of  $\beta_0$ .

(Refer Slide Time: 33:53)

$$\begin{aligned}
 E(\hat{\beta}_0) &= E(\bar{y} - \hat{\beta}_1 \bar{x}) \\
 &= E(\beta_0 + \beta_1 \bar{x} - \hat{\beta}_1 \bar{x}) \\
 &= \beta_0 + \beta_1 \bar{x} - \beta_1 \bar{x} \\
 &= \beta_0
 \end{aligned}$$

Both  $\hat{\beta}_1$  and  $\hat{\beta}_0$  are unbiased.

Sorry  $\hat{\beta}_0$  is also unbiased that means we are going to prove that expectation of  $\hat{\beta}_0$  is equal to  $\beta_0$ . This is equal to expectation of  $\bar{y} - \hat{\beta}_1 \bar{x}$ . So, what is  $\bar{y}$  equal to we proved in the previous slide  $\bar{y}$  is nothing but  $\beta_0 + \beta_1 \bar{x}$ . So, this is equal to expectation of  $\beta_0 + \beta_1 \bar{x} - \hat{\beta}_1 \bar{x}$ . Now, the expectation of  $\hat{\beta}_1$  just now we proved that expectation of  $\hat{\beta}_1$  is equal to  $\beta_1$ . So, this is equal to  $\beta_0 + \beta_1 \bar{x} - \beta_1 \bar{x}$  which is equal to  $\beta_0$ , so we prove that both  $\hat{\beta}_1$  and  $\hat{\beta}_0$  are unbiased.

(Refer Slide Time: 36:01)

$$\square V(\hat{\beta}_1) = \frac{\sigma^2}{S_{xx}}$$
$$\square V(\hat{\beta}_0) = \sigma^2 \left( \frac{1}{n} + \frac{\bar{x}^2}{S_{xx}} \right)$$

Next, will talk about the variance of the variance of beta 1 hat and beta naught hat the variance of beta 1 hat is equal to sigma square by S x x and variance of beta naught hat is equal to sigma square into 1 by n plus x bar square by S x x. Anyway I mean we need to know how to how to derive these things well.

(Refer Slide Time: 36:36)

Variance  $\hat{\beta}_0$  &  $\hat{\beta}_1$

$$V(\hat{\beta}_1) = V\left(\frac{\sum(x_i - \bar{x})(y_i - \bar{y})}{\sum(x_i - \bar{x})^2}\right)$$
$$= V\left(\frac{\sum(x_i - \bar{x})y_i}{\sum(x_i - \bar{x})^2}\right) = V\left(\sum c_i y_i\right)$$

where  $c_i = \frac{x_i - \bar{x}}{\sum(x_i - \bar{x})^2}$

$$V\left(\sum c_i y_i\right) = \sum c_i^2 V(y_i) = \sum c_i^2 \sigma^2$$

So, next we talk about the variance of variance of beta naught hat and beta 1 hat. So, the variance of beta 1 hat is equal to variance of what is beta 1 hat beta 1 hat is equal to summation x i minus x bar into y i minus y bar by summation x i minus x bar whole

square. Well now this can be written as the variance of summation  $x_i - \bar{x}$  into  $y_i$  by summation  $x_i - \bar{x}$  whole square. And this is nothing but see I before also I proved that this estimator is a linear combination of the observation  $y_i$ .

So, the variance of this quantity is and since  $y_i$   $y_i$  is are independent you know well this is equal to variance of summation  $C_i y_i$ , were  $C_i$  were  $C_i$  is equal to  $x_i - \bar{x}$  by summation  $x_i - \bar{x}$ . Now, we know that the variance of the variance of summation  $C_i y_i$  is equal to summation sum of variances  $C_i^2$  variance of  $y_i$ . This is true because because  $y_i$  s are  $y_i$  s are independent and we know that variance of  $y_i$  is equal to  $\sigma^2$  this is equal to summation  $c_i^2 \sigma^2$ . Now, what is summation  $C_i^2$  summation  $C_i^2$  we know this is this is  $C_i$ . So, variance of  $\hat{\beta}_1$  is equal to  $\sigma^2$  into summation  $C_i^2$  which is equal to summation  $x_i - \bar{x}$   $C_i^2$ .

(Refer Slide Time: 40:36)

$$\begin{aligned}
 V(\hat{\beta}_1) &= \sigma^2 \frac{\sum (x_i - \bar{x})^2}{[\sum (x_i - \bar{x})^2]^2} \\
 &= \frac{\sigma^2}{\sum (x_i - \bar{x})^2} = \frac{\sigma^2}{S_{xx}}
 \end{aligned}$$

So, summation  $x_i - \bar{x}$  whole square by summation  $x_i - \bar{x}$  whole square and the square of the whole thing. So, just replacing  $C_i^2$  by its value and this becomes  $\sigma^2$  by summation  $x_i - \bar{x}$  whole square, which is equal to  $\sigma^2$  by  $S_{xx}$  by notation. So, he proved that variance of  $\hat{\beta}_1$  is equal to  $\sigma^2$  by  $S_{xx}$ .

(Refer Slide Time: 41:54)

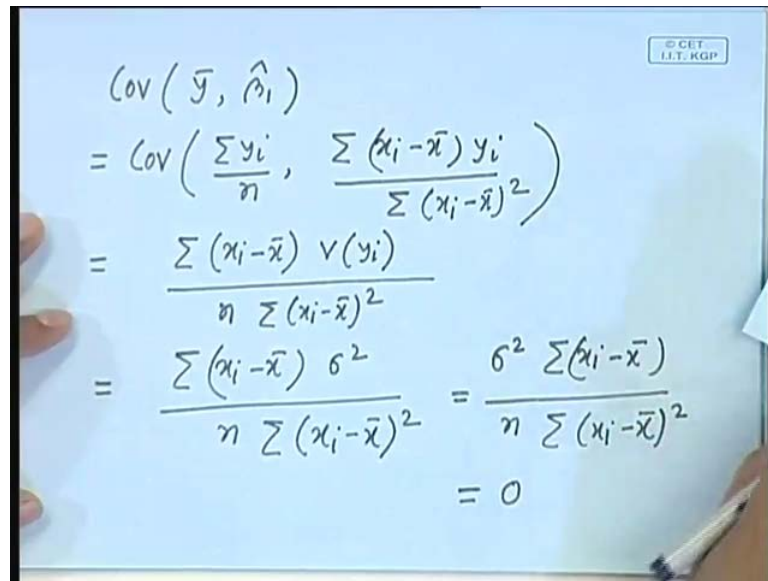

$$\begin{aligned}V(\hat{\beta}_0) &= V(\bar{y} - \hat{\beta}_1 \bar{x}) \\&= V(\bar{y}) + V(\hat{\beta}_1 \bar{x}) - 2\bar{x} \text{Cov}(\bar{y}, \hat{\beta}_1) \\&= \frac{\sigma^2}{n} + \bar{x}^2 V(\hat{\beta}_1) - 2\bar{x} \times 0 \\V(\bar{y}) &= V\left(\frac{1}{n} \sum y_i\right) \\&= \frac{\sum V(y_i)}{n^2} \\&= \frac{\sum_{i=1}^n \sigma^2}{n^2} = \frac{n\sigma^2}{n^2} = \frac{\sigma^2}{n}\end{aligned}$$

So, next we talk about the variance of beta naught hat variance of beta naught hat is equal to variance of y bar minus beta 1 hat x bar right. Now, this variance can be written as variance of y bar plus the variance of beta 1 hat x bar minus 2 times x bar the covariance of y bar and beta 1 hat right.

Now, you know the variance of y bar i hope you know it it is equal to its not difficult to prove that this is equal to sigma square by n. Let me prove this variance of y bar is equal to the variance of 1 by n summation y i know y i is an independent. That is assumption we made at the beginning because e i is an independent. So, epsilon i s are independent y i s are also an independent the variance of this quantity is equal to summation of variance of y i by n square right and variance of y i is equal to sigma square.

So, summation sigma square n times 1 to n y n square, so this is basically n sigma square by n square. This is equal to sigma square by n the variance of y bar is equal to sigma square by n, we know the variance of beta 1 hat and this is the constant quantity. So, the variance of this quantity is x bar square into the variance of beta 1 hat which is equal to which is equal to sigma square by S x x just we proved. Now, what about this covariance this is going to be this co-variance is going to be 0 this is 2 x bar into 0 into 0, but we need to prove this one. Ok the covariance between this can be proved that the covariance is equal to 0.

(Refer Slide Time: 45:07)

$$\begin{aligned} & \text{cov}(\bar{y}, \hat{\beta}_1) \\ &= \text{cov}\left(\frac{\sum y_i}{n}, \frac{\sum (x_i - \bar{x}) y_i}{\sum (x_i - \bar{x})^2}\right) \\ &= \frac{\sum (x_i - \bar{x}) \text{v}(y_i)}{n \sum (x_i - \bar{x})^2} \\ &= \frac{\sum (x_i - \bar{x}) \sigma^2}{n \sum (x_i - \bar{x})^2} = \frac{\sigma^2 \sum (x_i - \bar{x})}{n \sum (x_i - \bar{x})^2} \\ &= 0 \end{aligned}$$

The covariance between  $\bar{y}$  and  $\hat{\beta}_1$  is equal to the covariance between what is  $\bar{y}$  and  $\hat{\beta}_1$ .  $\bar{y}$  is equal to summation  $y_i$  by  $n$ . And  $\hat{\beta}_1$  is equal to summation  $x_i$  minus  $\bar{x}$  into  $y_i$  by summation  $x_i$  minus  $\bar{x}$  whole square. Now, this covariance is seen  $y_i$  are independent, so the covariance between  $y_i$  and  $y_j$  is equal to 0 when  $i$  is not equal to  $j$ . So, this is nothing but the summation of  $x_i$  minus  $\bar{x}$  the covariance between  $y_i$  and  $y_i$ . So, which is nothing but the variance of  $y_i$  right by summation  $x_i$  minus  $\bar{x}$  whole square and  $1/n$  here. This is equal to this is equal to summation  $x_i$  minus  $\bar{x}$  variance of  $y_i$  is equal to  $\sigma^2$  by  $n$  into summation  $x_i$  minus  $\bar{x}$  whole square. And this quantity see summation  $x_i$  minus  $\bar{x}$  is equal to 0.

That is why the numerator is 0, so this is equal to  $\sigma^2$  into summation  $x_i$  minus  $\bar{x}$  this quantity is 0 always by  $n$  into summation  $x_i$  minus  $\bar{x}$  whole square. So, this is nothing this is equal to 0, because of the fact that summation  $x_i$  minus  $\bar{x}$  is always equal to 0. So, he proved that so he proved that covariance is equal to 0.

(Refer Slide Time: 47:53)

The image shows a handwritten derivation on a light blue background. It starts with the variance of the intercept estimator  $\hat{\beta}_0$  as a function of the sample mean  $\bar{y}$  and the slope estimator  $\hat{\beta}_1$ . It then uses the variance of a linear combination of random variables. The variance of  $\bar{y}$  is derived from the variance of the sum of  $n$  independent observations  $y_i$ , each with variance  $\sigma^2$ . The final result is  $\frac{\sigma^2}{n}$ .

$$\begin{aligned} V(\hat{\beta}_0) &= V(\bar{y} - \hat{\beta}_1 \bar{x}) \\ &= V(\bar{y}) + V(\hat{\beta}_1 \bar{x}) - 2\bar{x} \text{Cov}(\bar{y}, \hat{\beta}_1) \\ &= \frac{\sigma^2}{n} + \bar{x}^2 V(\hat{\beta}_1) - 2\bar{x} \times 0 \\ &= \frac{\sigma^2}{n} + \frac{\bar{x}^2 \sigma^2}{S_{xx}} \\ V(\bar{y}) &= V\left(\frac{1}{n} \sum y_i\right) \\ &= \frac{\sum V(y_i)}{n^2} \\ &= \frac{\sum \sigma^2}{n^2} = \frac{n\sigma^2}{n^2} = \frac{\sigma^2}{n} \end{aligned}$$

That means the variance of beta naught hat is equal to sigma square by n plus x bar square into variance of beta 1 hat which is equal to sigma square by S x x which we just proved. This is sigma square by into 1 by n plus x bar square by S x x, so we found . So, we proved that both the beta naught and beta 1 they are unbiased estimated sigma square.

(Refer Slide Time: 48:48)

The image shows two handwritten equations on a light blue background. The first equation gives the variance of the intercept estimator  $\hat{\beta}_0$  as  $\sigma^2 \left( \frac{1}{n} + \frac{\bar{x}^2}{S_{xx}} \right)$ . The second equation, separated by an ampersand, gives the variance of the slope estimator  $\hat{\beta}_1$  as  $\frac{\sigma^2}{S_{xx}}$ .

$$\begin{aligned} V(\hat{\beta}_0) &= \sigma^2 \left( \frac{1}{n} + \frac{\bar{x}^2}{S_{xx}} \right) \\ \& \\ V(\hat{\beta}_1) &= \frac{\sigma^2}{S_{xx}} \end{aligned}$$

And also we proved that the variance of beta naught hat is equal to sigma square 1 by n plus x bar square by S x x and the variance of beta 1 hat is equal to sigma square by S x x. Now, see both the variance formula the variance for beta naught hat and beta 1 hat

both the involved a sigma square. So, but we do not know what is the value of sigma square, so sigma square must be replaced by its estimators. So, you need to estimate the value of sigma square, so next we talk about the estimation of sigma square, how to how to estimate sigma square.

(Refer Slide Time: 50:06)

Estimation of  $\sigma^2$

$$SS_{Res} = \sum e_i^2 = \sum (y_i - \hat{y}_i)^2 \quad E\left(\frac{SS_{Res}}{n-2}\right) = \sigma^2$$

$$= \sum (y_i - \hat{\beta}_0 - \hat{\beta}_1 x_i)^2 \quad \hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x}$$

$$= \sum (y_i - \bar{y} - \hat{\beta}_1 x_i + \hat{\beta}_1 \bar{x})^2$$

$$= \sum [y_i - \bar{y} - \hat{\beta}_1 (x_i - \bar{x})]^2$$

$$= \sum (y_i - \bar{y})^2 + \hat{\beta}_1^2 \sum (x_i - \bar{x})^2 - 2\hat{\beta}_1 \sum$$

Estimation of sigma square well the estimation of sigma square is obtained from the residual sum of square SS residual. And finally will be proving that expected value of SS residual by n minus 2. This thing is equal to sigma square that means the sum of residual sorry residual sum of square by n minus 2 is unbiased estimated of sigma square. And will be we can compute the value of residual sum of square given a set of observations and we know n. So, using this formula we can we can estimate the value of the population variance sigma square. So, well we need to prove this one SS residual is equal to summation e i square. That we know and which is equal to the difference the ith residual is the difference between ith observation and the estimated value y i at.

So, this is equal to this is equal to square here this is equal to summation y i minus what is y i at is equal to beta naught hat minus beta 1 hat x i whole square. So, what we do here is that we know beta naught hat his equal to just trying to find a convenient form for SS residual. So, beta naught hat is equal to y bar minus beta 1 hat x bar right. So, will just plug this value here this is equal to summation y i minus y bar minus beta 1 hat x i plus beta 1 hat x bar whole square.

This is equal to summation  $y_i - \bar{y} - \beta_1 \hat{x}_i - \bar{x}$  whole square, now this can be written as summation  $y_i - \bar{y}$  whole square minus. Let me write plus  $\beta_1 \hat{x}_i - \bar{x}$  whole square minus 2 times  $\beta_1 \hat{x}_i - \bar{x}$  into  $y_i - \bar{y}$  right.

(Refer Slide Time: 54:23)

ESTIMATION OF  $\sigma^2$

$$\begin{aligned}
 SS_{Res} &= \sum e_i^2 = \sum (y_i - \hat{y}_i)^2 \quad E\left(\frac{SS_{Res}}{n-2}\right) = \sigma^2 \\
 &= \sum (y_i - \hat{\beta}_0 - \hat{\beta}_1 x_i)^2 \quad \hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x} \\
 &= \sum (y_i - \bar{y} - \hat{\beta}_1 x_i + \hat{\beta}_1 \bar{x})^2 \\
 &= \sum [y_i - \bar{y} - \hat{\beta}_1 (x_i - \bar{x})]^2 \\
 &= \sum (y_i - \bar{y})^2 + \hat{\beta}_1^2 \sum (x_i - \bar{x})^2 - 2\hat{\beta}_1 \sum (x_i - \bar{x})(y_i - \bar{y})
 \end{aligned}$$

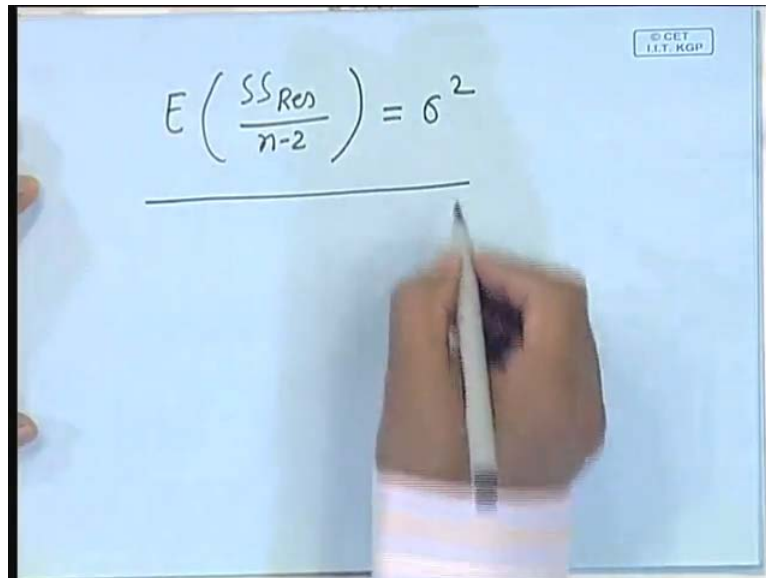

So, this can be written in the form  $S_{yy} + \hat{\beta}_1^2 S_{xx} - 2\hat{\beta}_1 S_{xy}$  is  $x$  minus 2  $\hat{\beta}_1$  is  $x$  y, just notation.

(Refer Slide Time: 54:55)

$$\begin{aligned}
 &= S_{yy} + \hat{\beta}_1^2 S_{xx} - 2\hat{\beta}_1 S_{xy} \\
 &\quad \hat{\beta}_1 = \frac{S_{xy}}{S_{xx}} \\
 &= S_{yy} + \hat{\beta}_1^2 S_{xx} - 2\hat{\beta}_1 \hat{\beta}_1 S_{xx} \\
 &= S_{yy} + \hat{\beta}_1^2 S_{xx} - 2\hat{\beta}_1^2 S_{xx} \\
 \boxed{SS_{Res} = S_{yy} - \hat{\beta}_1^2 S_{xx}} \quad E-SS
 \end{aligned}$$

Now, see we know that  $\hat{\beta}_1$  is equal to  $\frac{S_{xy}}{S_{xx}}$  right so what I will do is that I will replace this  $S_{xy}$  by  $\hat{\beta}_1 S_{xx}$ . So, this is equal to  $S_{yy} - \hat{\beta}_1^2 S_{xx}$ . Now, replace this one by  $\hat{\beta}_1 S_{xx}$  into this becomes  $S_{yy} + \hat{\beta}_1 S_{xx} - 2\hat{\beta}_1 S_{xx}$ . This is square here square here  $\hat{\beta}_1^2 S_{xx}$ , so which is equal to  $S_{yy} - \hat{\beta}_1^2 S_{xx}$ . This is a convenient form of SS residual and we are going to use this one in the next class. To prove that because you need to find the expected value of this one to prove.

(Refer Slide Time: 56:45)

A hand is shown writing the equation  $E\left(\frac{SS_{Res}}{n-2}\right) = \sigma^2$  on a whiteboard. The equation is written in black marker and is underlined. A small logo in the top right corner of the whiteboard reads "© CET I.I.T. RGP".
$$E\left(\frac{SS_{Res}}{n-2}\right) = \sigma^2$$

The expectation of SS to prove that expectation of SS residual by  $n - 2$  equal to  $\sigma^2$  well, so will continue in the in the next class.

Thank you.
