**Properties of Riemann Stieltjes Integral**

(Refer Slide Time: 00:35)

So, yesterday we were discussing this theorem and theorem was suppose,  $f$  is bounded on the closed interval  $a, b$  and  $f$  has only finitely many points of discontinuities on the closed interval  $a, b$ ; and  $\alpha$  is continuous at every point at which,  $f$  is discontinuous then  $f$  is a Riemann Stieltjes Integral. So, actually what he says is that if,  $f$  is given to be a bounded function, but it has a point of discontinuities over the interval  $a, b$ , and the number of the discontinuous points are finite. And  $\alpha$  is such which is continuous at the point, where the  $f$  is having point of discontinuity, where  $f$  is discontinuous  $\alpha$  is continuous. Then in that case the function  $f$  will be a point of the class  $R \alpha$ ; that is the Riemann Integrable, Stieltjes Integrable function with respect to  $\alpha$ .

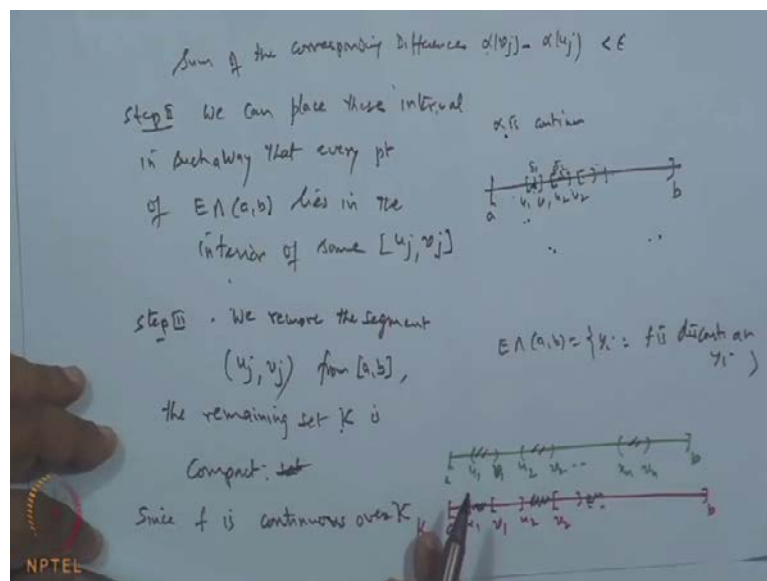

So, in particular when  $\alpha$  is equal to  $x$ , then you can say every bounded function which has a finitely many discontinuous points over the interval  $a, b$  must be a Riemann Integral functions. And we have started the proof also, the proof were a what is given is the  $f$  is a bounded function. So, we can take the supremum value of  $f x$  over the interval  $a$

b as suppose  $m$ , this is over the interval  $a, b$ , this one and let  $\epsilon$  be greater than given.

Now, suppose  $E$  is the collection of those points where the function has a discontinuity and this is finite. So, let these are the points where the function has a discontinuity and this is finite. So, let these are the points where the function has a point of discontinuity since they are a finite number. So, we can enclose them by means of a intervals  $u_j, v_j$  closed intervals like this and the length can be chosen very, very small sufficiently because these are single term points and all these subinterval is a part of the interval  $a, b$ .

Now, since  $f$  is continuous at the point this point. So, by definition if we take any  $\epsilon$  greater than  $0$ , then the image of the  $f(x)$  when  $x$  belongs to this interval must lie within this  $\epsilon$  neighbourhood. So, suppose there are  $n$  sub intervals end points where the function  $f$  is discontinuous, so we are getting  $n$  sub intervals of this type and if we choose the  $\epsilon$  as  $\epsilon/n$ . Then over each one we can say this is less than  $\epsilon/n$  and total sum of the  $f(v_j) - f(u_j)$  will be less than  $\epsilon$ , because  $f$  is continuous.

(Refer Slide Time: 03:15)

So, once it is  $f$  is continuous we can make this for given  $\epsilon$ . We can choose the  $\delta$  sufficiently small number say  $\delta_1, \delta_2, \dots, \delta_n$  such that whenever the

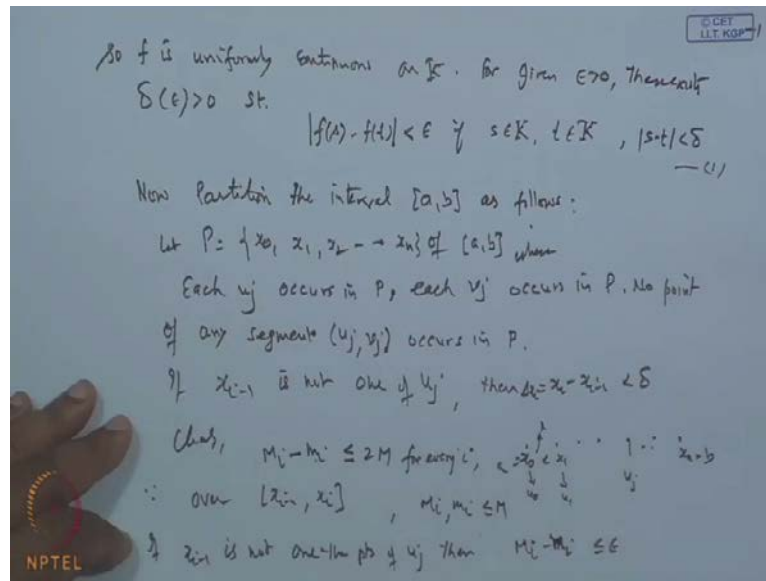

point is there it will be lying between  $\alpha$ ,  $\epsilon$  then  $\epsilon$  plus,  $\epsilon$  plus total is  $\epsilon$  by  $n$   $\epsilon$  by  $n$  and total is less than  $\epsilon$ , this we can do it with the help of continuity of  $\alpha$ . So, this was the discussion.

Now, what we do in second case that we will place these intervals which we have chosen  $u_j, v_j$  in such a manner over the interval  $a, b$ ; that the point of the discontinuity of  $f$  lies within these intervals. So, let us place this or you can say that if we take a point  $E$  intersection  $a, b$ . The  $E$  intersection  $a, b$  is set of those points which are common in  $E$  and  $a, b$ .  $E$  is the set of those points where the function is discontinuous. So, basically we are choosing all the points where the function is discontinuity, within the subintervals  $u_1, v_1, u_2, v_2$  all you can one in one of the point all the points will lie within this lie. So, lies in the interior of the clear. So, up to here we have discussed.

Now, what we do is in the step three, we remove we remove the open interval remove the segment  $u_j, v_j$  from the close interval  $a, b$ . It means what we are doing is that this is our interval  $a, b$  and here is the point say  $u_1, b_1, u_2, u_1, v_1, u_2, v_2$  and like this suppose these are the points say like  $u_n$  say  $v_n$ , then what we do is we are removing this portion, this portion we are removing.

So, we are getting now after removing  $a$  into  $u_1, a, u_1$  this is 1 then we start with  $v_1, u_2$  and like this, then we start with  $v_2$  and continued this way and up to here say  $v$ . So, this set  $K$  which is which in which these things are not available these things are not available. So, this set  $K$  forms a compact set. So, once we remove the segment  $u_j, v_j$  from  $a$  then the remaining set  $K$  is compact, because it is a finite union of the compact closed and compact set intervals like this. So, it is a compact set compact is compact or compact set. Now, function  $f$  is given to be continuous since  $f$  is continuous over  $K$ , because the point of discontinuity we have already removed. So,  $f$  is continuous over  $K$  and  $K$  is compact set. So, every continuous function on a compact is uniformly continuous.

(Refer Slide Time: 07:19)

So,  $f$  will be. So,  $f$  is uniformly continuous is uniformly continuous function on  $K$ , uniform continuous function on  $K$  clear this one. So, by definition what is a  $f$  is uniform means, so for a given epsilon greater than 0. So, for given epsilon greater than 0 there exist, there exist a delta which depends only on epsilon not the point greater than 0, such that the mod of  $f(s) - f(t)$ , this will remain less than epsilon if  $s$  belongs to  $K$ ,  $t$  belongs to  $K$  and mod of  $s - t$  is less than delta, by definition of the uniform continuity let it be 1.

Now, let us partition now partition, partition the interval  $a, b$  as follows follows suppose  $p$  is the partition  $p$  is the let  $p$  is the partition  $x_0, x_1, x_2, \dots, x_n$  of  $a, b$ ;  $a, b$ ; then we take such partition that each  $u_j$  is a partition where, where  $u_j$  each  $u_j$  occurs in  $P$  each  $v_j$  each  $v_j$  occurs in  $P$ , means this  $u_1, u_2, u_n, v_1, v_2, v_n$  these are the one of the points of the partitioning point of the interval  $a, b$ ,  $a, b$  and no point and no point of any segment, any segment  $u_j, v_j$  this open segment occurs in  $P$ .

This is the restriction we are putting we are choosing the partition in such a way that, the coronal points of this subintervals which are covering the point of discontinuities are basically coinciding with the partitioning point, but none of the point in between in this inside this interval are the partitioning point are the points of the partition this is one thing, second thing is in case if  $x_{i-1}$  suppose is not is not one of the  $u_j$  because

this might be possible number of the points are finite may be the number of points are not as sufficient as the partitioning point is there.

So, some of the exercise will remain untouched. So, if  $x_i$  is not one of the  $u_j$  then what we do is. Then we put the restriction  $a$  that that  $x_i - x_{i-1}$ , that is the  $\Delta x_i$  this should be less than  $\delta$  this is our restriction. So, once you have partitioning this point it means now we get this. So, this is our  $x_0, x_1, x_2, x_3, x_n$  and so on, say this is  $a$  this is  $b$  and then we are coinciding this say suppose  $u_0, u_1$  and so on continue suppose here is  $u_j$  and after this we are not getting anything, and the points in between  $u_j$  are not there, are not there one thing.

So, let us see suppose we take any interval clearly over any subintervals  $M_i$  minus small  $m_i$  this will remain less than equal to  $2m$  why? Because what is our  $m$  is the supremum value we have chosen, this is  $m$  is the supremum value over interval. So, if I consider the  $x_i - x_{i-1}$  clearly because over the interval over  $x_i$  minus to  $x_{i-1}$  the minimum value of the function is  $m_i$  supremum value is  $a$ . So,  $M_i$  as well as small  $m_i$  both are less than equal to  $m$ . So,  $M_i - m_i$  is less than equal to  $2m$  this is true for each  $i$  for every  $i$  for every  $i$  this is true, and further if  $x_{i-1}$  is not one of the point if  $x_i - x_{i-1}$  is not one of the point of  $u_j$  unless this is not one of the point then the difference between  $M_i - m_i$  this difference can be made less than equal to  $\epsilon$ , why? Because of this part because a function is function is continuous as well as uniformly continuous over  $a, b$ . So, if the point  $x_i - x_{i-1}$  less than  $\delta$ , if this is because we have put this is not one of the point then this difference is less than  $\delta$ . So, because of the form this difference should be less than  $\epsilon$ .

(Refer Slide Time: 13:57)

$$\begin{aligned}
 U(P, f, \alpha) - L(P, f, \alpha) &= \sum_{i=1}^n (M_i - m_i) \Delta x_i = \sum_k M_i \Delta x_i + \sum_{\Delta x_i \geq \epsilon} \Delta x_i \\
 &= \epsilon \sum_{i=1}^n \Delta x_i + 2M\epsilon \\
 &= \epsilon \cdot (x(b) - x(a)) + 2M\epsilon
 \end{aligned}$$

Since  $\epsilon$  is arbitrary, so  $f \in R(\alpha)$

Theorem. Suppose  $f \in R(\alpha)$  on  $[a, b]$ ,  $m \leq f \leq M$ ,  $\phi$  is continuous on  $[m, M]$ , and  $x(x) = \phi(f(x))$  on  $[a, b]$ . Then  $x \in R(\alpha)$  on  $[a, b]$

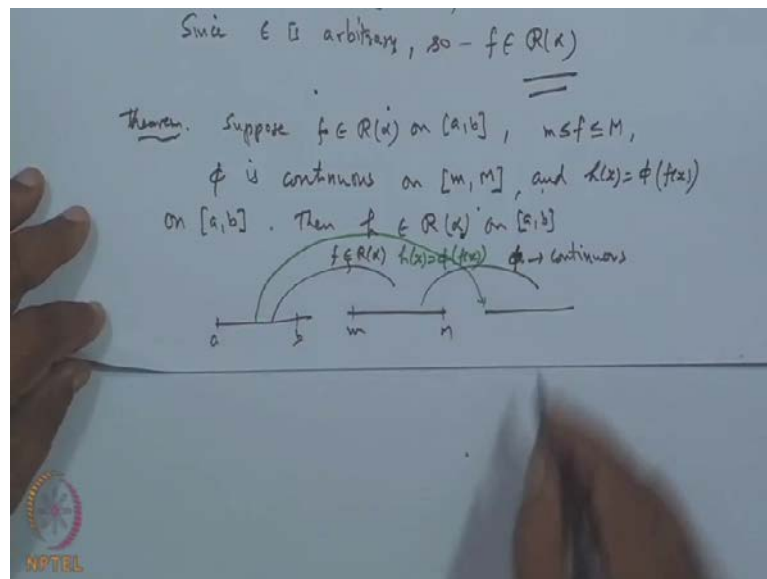

So,  $M_i - m_i$  will be less than epsilon. So, that for each one will be less than equal to epsilon hence, if we construct the proof upper sum minus lower sum. Upper sum of the function  $f$  with respect to  $\alpha$  over the partition  $P$  minus lower sum of the function  $f$  with respect to  $\alpha$  over the partition  $P$ , this is basically what sigma  $i$  equal to one to  $n$ , say  $m_i - M_i$  into  $\Delta x_i$ , which can be broken up as sigma over  $k$ , plus sigma over  $a, b$  minus  $k$ , because the dropped interval these which are dropped.

So, in this case is over  $K$  this is less than epsilon this is less than epsilon. So, we get epsilon into sigma of this part, but sigma of this  $\Delta x_i$  is one to  $n$  is nothing but the  $x(b) - x(a)$ . So, this will and this part over this  $m$  already we have function is bounded. So,  $M_i - m_i$  is less than equal to  $2M$  and since sigma of  $\Delta x_i$   $x(b) - x(a)$  minus this total is less than epsilon, this is because of the continuity this sum of this corresponding is less than epsilon. So, we get from here is that this is less than epsilon and this part will be epsilon  $x(b) - x(a) + 2M\epsilon$  but epsilon is arbitrary but epsilon is arbitrarily small number.

So, this shows that the right hand side will go to 0 and the left hand side. So,  $f$  will be the element of this. So, this is what proof. Now another results also which is interesting the result says suppose  $f$  is,  $f$  is in  $R(\alpha)$  on the close interval  $a, b$  Riemann Stieljes Integral with respect to  $\alpha$  over the interval  $a, b$  and  $f$  is bounded function, bounded by say  $M$

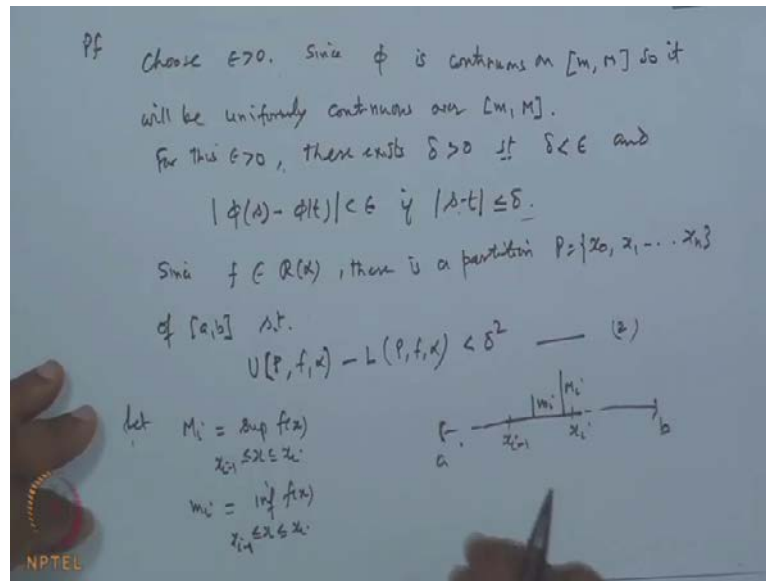

and capital M.  $\phi$  is continuous on the close interval  $m$  and capital M this  $\phi$ , then and  $h(x) = \phi(f(x))$  on the close interval  $a, b$  on the close interval  $a, b$ . Then this result says the  $h$  belongs to  $R(\alpha)$  that is Riemann Stieljes Integral on. So, if function  $f$  is Riemann Integrable function and  $\phi$  is a continuous function on the  $m$ . That is the where the function have a range set, range of the set  $f$  is  $m$  interval then the composition of this function, continuous image of  $a$  of a Riemann Stieljes Integral function will be a Riemann Stieljes Integral that is what he says.

(Refer Slide Time: 17:41)

So, this is just like that here we are taking this function this is our interval  $a, b$ , function  $f$  is given. So, here is our  $m$  and capital  $M$ , where the function attains the minimum and maximum value and over the function  $h$  is defined,  $h$  is defined. So, what is  $a$  when you combine the  $h \phi$  composition position  $f(x)$  then it will transfer directly from here to here, which is  $h$  composition  $h(x) = \phi(f(x))$  equal to  $\phi$  composition  $f(x)$ , and if this is in  $R(\alpha)$  this is this function  $\phi$  or this  $\phi$  sorry this is  $\phi$ ,  $\phi$  and if this  $\phi$  is continuous and this is an this is continuous this is in  $R(\alpha)$ ,  $R(\alpha)$  then our  $h$  will be in  $R(\alpha)$  that is what is. So, let's see the proof of it.

(Refer Slide Time: 18:51)

Choose epsilon greater than 0, now given that phi since phi is continuous on the closed interval m and capital M. So, this it will be uniformly continuous, uniformly continuous over this interval m and capital M, because every continuous function over a compact set is uniformly continuous. So, by definition epsilon we have already chosen. So, let us choose the delta. So, for this epsilon for this epsilon greater than 0, which is chosen here there exist, there exist a delta greater than 0 such that.

Now I am putting the restriction on this delta is smaller than epsilon, because this any delta then all the delta which are less putting delta to be less than epsilon this image will go there. So, let us put take the delta to be equal to epsilon and phi of s minus phi of t is less than epsilon if mod of s minus t is less than equal to delta. What he says is for the, because phi is uniformly continuous. So, for any epsilon greater than 0 there exist a delta, such that image of this any point in which satisfy this condition must fall within this range. Now suppose I take delta which is greater than epsilon then I can pick up an another delta which is smaller than this less than epsilon. So, the again this image will fall here. So, nothing we are not losing anything, but it will be advantageous while proving the whole theorem.

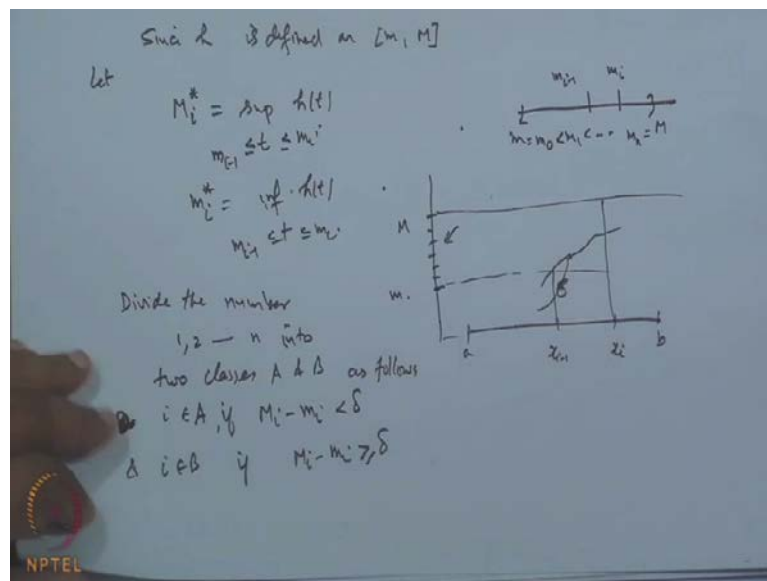

Now, further since f is given to be an element in R alpha. So, by definition the result a necessary and sufficient condition for a function to be a Riemann Stieljes Integral on viewing the class of it, if there exist some partition for a given epsilon there exist some

partition such that upper sum minus lower sum is less than this. So, let  $f$  belongs to this then there is a partition, there is a partition say  $P$ ,  $x_0, x_1, x_2, \dots, x_n$  of  $a, b$ ,  $f$   $a, b$  such that, such that the upper sum of the function  $f$  with respect to  $P$  minus lower sum of the function  $f$  with respect to  $P$ , over the same partition is less than say  $\delta$  square clear.

So, this we are getting. So, let it be equation two, now over the subintervals we have let  $x_{i-1}, x_i$  plus this is the sub interval of this partition  $a, b$  this is the partition  $a, b$  this is now here the function attains this minimum value say  $m_i$  and maximum value is suppose capital  $M_i$ . So, let  $m_i$  and capital  $M_i$ ,  $m_i$  is the supremum of the function  $f(x)$  when  $x$  lies between  $x_{i-1}$  to  $x_i$  while the  $M_i$  small  $m_i$  is the infimum value of the function  $f(x)$  when the  $x$  lies between  $x_{i-1}$  to  $x_i$  clear let be this one.

(Refer Slide Time: 23:01)

Now, function  $h$  is defined since  $h$  is defined,  $h$  is defined because what the result is the  $h$  is  $f$  is Riemann Integral,  $f$  is this and  $\phi$  is continuous function  $\phi$  is continuous on this and  $h$  is a function which is basically  $\phi$  of  $h f x$ . So, what are the range of  $f h$  is defined on it. So, basically the  $h$  is defined on  $h$  is defined on  $m$  and capital  $M$ . So, in this case when you partitioning this  $m, n$  say  $m$  and capital  $M$  and suppose I partition it say  $m$  naught less than  $m_1$  and. So, on say here is  $m, n$  less than  $m$ . So, if we picked up the  $m_i$  minus one and  $m_i$ .

Now in this case now you consider the upper and lower bound for the function  $h$  then we say we denote this as let us denote, let  $M_i^*$  is the supremum value of  $h$  t, I am using the  $t$  where  $t$  lies between  $m_{i-1}$  to  $M_i$  and small  $m_i^*$  is the infimum value of  $h$  t when  $t$  lies between  $m_{i-1}$  to  $m_i$ , is it not just i am taking this one now. So, this is our interval  $a$   $b$  here I am taking one say subinterval say  $x_i$ ,  $x_i - 1$  and here is say suppose image is.

So, this is our say  $m_i$  and here is capital  $M$  say this is our. So, basically this will be the all the functions will be somewhere here clear. In fact, this is wrong this one like this. So, here is now we are dividing here and then  $h$  is defined over this  $h$  is defined on this side now let us choose the suppose for  $i$ , divide the number divide the number one, two, three  $n$  into two classes, two classes.

First class is  $A$ , two class is  $A$  and  $B$  as follows. When  $i$  belongs to  $A$  for  $I$  belongs to  $A$  our choice of  $\delta$  shows,  $i$  belongs to  $A$  means that is if  $i$  belongs to  $A$  for  $i$  belongs to  $A$  or a  $i$  belongs to  $A$  if or just  $i$  belongs to  $A$  if  $M_i - m_i$  is less than  $\delta$  and  $i$  belongs to  $B$ , if  $M_i - m_i$  is greater than or less than  $\delta$ . So, this will be like this.

(Refer Slide Time: 26:58)

for  $i \in B$ ,  $M_i^* - m_i^* \leq 2k$  where  $k = \sup_{m \leq t \leq M} |f(t)|$

Use (2)

$$U(P, \delta, \alpha) - L(P, \delta, \alpha) = \sum_{i=1}^n (M_i^* - m_i^*) \Delta x_i < \delta^2$$

$$\delta \sum_{i \in B} \Delta x_i \leq \sum_{i \in B} (M_i - m_i) \Delta x_i < \delta^2$$

$$\Rightarrow \sum_{i \in B} \Delta x_i < \delta \quad (3)$$

Consider

$$U(P, \delta, \alpha) - L(P, \delta, \alpha) = \sum_{i \in A} (M_i^* - m_i^*) \Delta x_i + \sum_{i \in B} (M_i^* - m_i^*) \Delta x_i$$

$$\leq \epsilon (\alpha(b) - \alpha(a)) + 2k.$$

Now picked up now class one, so for  $i$  belongs to. So, for  $i$  belongs to  $A$ , what is our when  $i$  is in a  $M_i$  minus small  $m_i$  is  $\delta$ . So, in this case what is the  $M_i^*$  minus  $m_i^*$  star small  $m_i^*$  star this will be because  $\phi$  is what  $\phi$  is uniformly continuous. So, if  $i$

belongs to  $A$ , it means it satisfies this condition, once it satisfies this condition then because the  $h$  of  $\phi$  defined on what on this interval. So, is it satisfies this condition therefore, the difference of this  $M_i^*$  minus small  $m_i^*$  must be less than  $\epsilon$ .

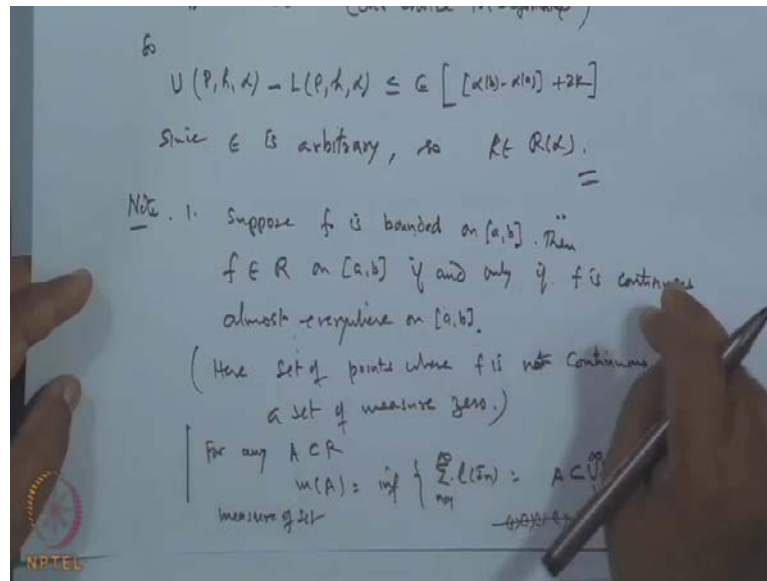

So, since our  $i$  belongs to this. So, our choice of choice of  $\delta$  choice of  $\delta$  shows  $M_i^* - m_i^*$  is less than  $\epsilon$  and this follows from, from this equation that is the relation I will say the relation is say  $x$ . So, it follows from the relation star, so nothing but this. So, first thing and if for  $i$  belongs to  $B$ , where this greater than or equal to  $\delta$ , we have in this interval the  $M_i^* - m_i^*$  is less than equal to  $2K$ , where  $K$  stands for the supremum value of the  $\phi$  when  $t$  lies between  $m$  and capital  $M$ .

So, supremum value and since it is greater than. So, use the condition two, condition two is this condition we have taken, that is  $m_i - \delta^2$  where is the  $\delta^2$  condition. So, this is condition two this is our condition two  $M_i - m_i - \delta^2$  is less than  $\delta^2$ . So, use the condition two. So, use two then in that case the  $U P f_\alpha - L P f_\alpha$  this is what. This is  $\sum_{i=1}^n (M_i - m_i - \delta^2)$ , but if we take and this is given to be less than  $\delta^2$  this is given to be  $\delta^2$  given

Now, if I take the only for  $\sum_{i=1}^n (M_i - m_i - \delta^2)$  over the set  $b$  only, then obviously it will remain less than  $\delta^2$  because this sum is smaller than this. So, it is less than  $\delta^2$ , but this will be  $x$  w equal to what over  $v$  this is greater than less than  $\delta$ . So, it is  $\delta \sum_{i \in B} \delta^2$ . So, what this imply this implies that  $\sum_{i \in B} \delta^2$  when  $i$  belongs to  $B$  is basically less than  $\delta$  let it be three. Now, consider the partition now consider the upper sum of the function  $h$  with respect to  $\alpha$  minus the lower sum of  $h$  with respect to  $\alpha$  and this we can divide in two parts when  $i$  belongs to  $A$ ,  $M_i^* - m_i^* - \delta^2$  plus when  $i$  belongs to  $B$ ,  $M_i^* - m_i^* - \delta^2$

Now, see this will be  $M_i^* - a$  when  $i$  belongs to  $A$  we have already justified this is less than  $\epsilon$ . So, this is basically less than  $\epsilon$  and then  $\delta^2$  will be remain less than the  $v \sum_{i \in B} \delta^2$  nothing but less than  $\alpha b - \alpha a$ . So, we get this part the second portion is this entire thing is less than  $2K$  because this is  $2K$ . So, it is less than  $2K$  and then over  $B$  the  $\sum$  is less than  $\epsilon$   $\sum$  is less than this  $\delta^2$  when you choose what is  $i \sum$  is less than  $\delta$ .

(Refer Slide Time: 32:16)

So, it is delta. So, once it delta, but delta is less than epsilon, this is our choice in the very beginning, beginning of this we have taken delta to be less than epsilon. So, we can choose the delta outside so we get  $P, h, \alpha$  minus  $L, P, h, \alpha$  is less than equal to epsilon alpha outside what you are getting is  $\alpha b$  minus  $\alpha a$  plus  $2K$ , but epsilon is arbitrary since epsilon is arbitrarily.

So, this that satisfy the sufficient necessary condition of that theorem, therefore  $h$  must be in  $R$  alpha and that proves the results. So, that proves the results. Now, let's come to, now as a we will not show that, but one note or result we will see then proof we will see, while going for the exercise we will do the proof for this the result is here. What this says is suppose  $f$  is bounded on the close interval  $a b$  then  $f$  is Riemann Integral on the close interval  $a b$  if , if and only if and only if,  $f$  is continuous almost everywhere on  $a b$ .

In fact, the concept of the almost everywhere this is a concept which is given in the measure theory measure integration, but what is the meaning of almost everywhere. Suppose a property holds everywhere except at some point and that set of those points form a measure 0. Then we say the property holds almost everywhere that is, so here we mean the set of points where  $f$  is not continuous,  $f$  is not continuous forms a set of measure 0.

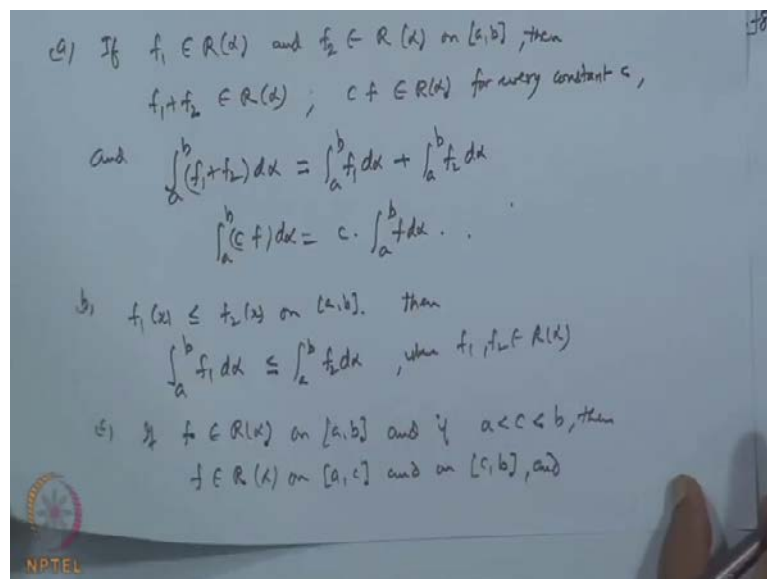

Measure 0 it means the length of that set measure of that set is 0, because when it is a interval we say the measure of the set  $a$  is a interval interval is the  $b$  minus  $a$ , but if the

set  $A$  contains the point of real numbers lying on the real line and they are scattered you cannot say that  $s$  a difference between the last point, and the first point is the length of the interval. So, it cannot be a measure it will be more value than whatever actually have.

So, what we do here that we find if in arbitrary set for an arbitrary set, for any set  $A$  which is a subset of  $\mathbb{R}$ . The measure of the set  $A$  is define as measure of this is out of course, thus I want the measure of a set  $A$ , is the infimum value of  $\sum_{n=1}^{\infty} \text{length}(I_n)$ ,  $n$  is one to infinity such that the countable union of  $I_n$  covers  $A$ . So, what we do is we consider the intervals  $I_1, I_2, \dots, I_n$  an open intervals an open intervals where these interval covers the point of the set  $A$ , then find out the length take the summation and then change the interval again take the infimum value.

So, if infimum exist we say it is a measure of the set  $A$ , where  $I_n$  is an open interval. So, this is what we have, but we will not discuss in detail but so whenever the set is function is continuous except at the point which forms a set of measure 0, then the function must be a Riemann Integral function. So, because every continuous function is Riemann Integrable, but the function, which are even not continuous a bounded functions having a simple continuity point of discontinuity and then those numbers are forms a measure 0 it will be a Riemann Integrable function.

(Refer Slide Time: 37:14)

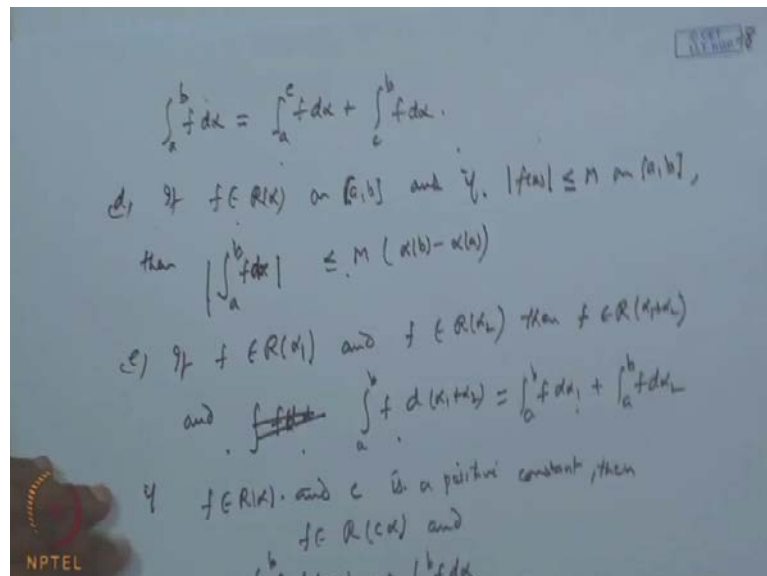

So, that is what is a now let's see the some few properties of the Riemann Stieljes Integrals, we will list the proof property and proof one or two will be good enough now

if  $f_1$  is a Riemann Stieljes Integral with respect to  $\alpha$ ,  $f_2$  is a Riemann Stieljes Integral with respect to  $\alpha$  on the close interval  $a, b$ , then the sum  $f_1$  plus  $f_2$  will also be Riemann Stieljes Integral with respect to  $\alpha$  and  $c f$  will also be a Riemann Stieljes Integral with respect to  $\alpha$  for every constant.

Constant  $c$  and the integral  $a$  to  $b$ ,  $f_1$  plus  $f_2$   $d\alpha$  the Riemann Stieljes Integral, where sum of it will be sum of the integrals  $f_1 d\alpha$  plus  $a$  to  $b$ ,  $f_2 d\alpha$  and  $c$  times  $f d\alpha$  is  $c$  multiply by  $a$  to  $b$   $f d\alpha$ . So, this is the first result. Second result says if suppose  $f_1$  and  $f_2$  are the two integral if  $f_1$  and  $f_2$  are the two functions such that  $f_1(x)$  is less than equal to  $f_2(x)$  on the close interval  $a, b$  and they are also Riemann Stieljes Integral and then then integral  $a$  to  $b$   $f_1 d\alpha$  is less than equal to integral  $a$  to  $b$ ,  $f_2 d\alpha$  of course, where  $f_1$  and  $f_2$  both are in  $R_\alpha$ .

Third property is if  $f$  is if  $f$ , belongs to  $R_\alpha$  that is Riemann Stieljes Integral on the close interval  $a, b$ ; and if and if  $a$  is less than  $c$  less than  $b$  then  $f$  is  $f$  is Riemann Stieljes Integral on the close interval  $a, c$ , as well as on  $c, b$  means if we divide  $a, b$  into two parts  $a, c$  to  $c, b$  then over each subinterval function  $f$  will remain Riemann Stieljes Integral with respect to same  $\alpha$  and the value of integral will be the sum of this two and integral

(Refer Slide Time: 40:02)

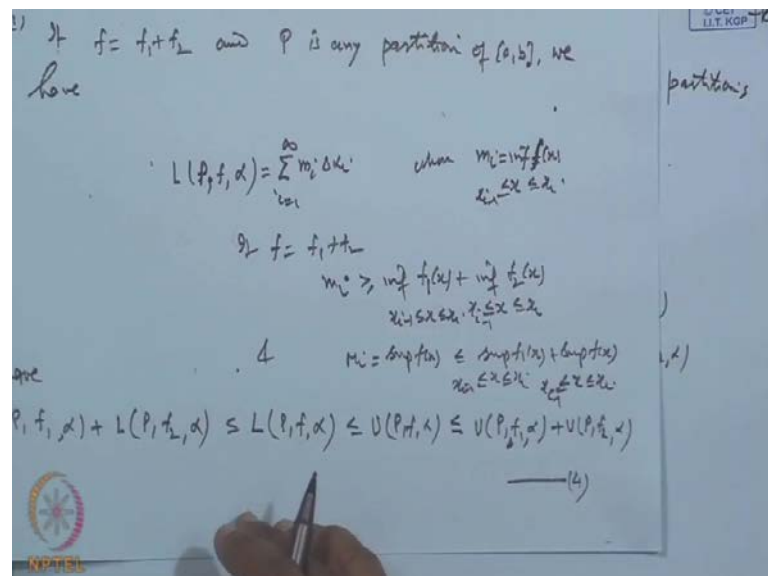

$a$  to  $b$   $f d\alpha$  is the same as  $a$  to  $c$   $f d\alpha$  plus  $c$  to  $b$   $f d\alpha$ . Forth property is if  $f$  is a Riemann Stieljes Integral with respect to  $\alpha$  on the close interval  $a, b$ , close interval  $a, b$  and if, the function  $f(x)$  is bounded by  $m$  on the close interval  $a, b$ ; then integral  $a$  to  $b$   $f$

$\int_a^b f(x) d\alpha \leq M(\alpha(b) - \alpha(a))$

Modulus of this d alpha then e property, if f is if f is Reimann Stieljes Integral with respect to monotonic function alpha one and f is a Reimann Stieljes Integral with respect to function alpha means f is Riemann Stieljes Integral with respect to the two monotonic functions alpha 1 minus alpha 2 respectively are there then f will remain Riemann Stieljes Integral with respect to the sum of these alpha 1 plus alpha 2, because if the alpha 1 and alpha 2 are monotonic increasing the summation will also monotonic increasing if they are monotonic decreasing they will also be monotonic decreasing and hence and integral of f alpha 1 d alpha 1 integral f d alpha 1 plus alpha 2 over a to b is the same as a to b f d alpha 1 plus a to b f d alpha 2 and f.

If f is Riemann Stieljes Integral with respect to alpha and c and c is a positive constant positive constant then then f is Riemann stieljes integral with respect to c alpha and integral of this a to b, f d c alpha is c times a to b, f d alpha. The proof of this results property follows by using the definition itself, but however, we will see the proof of the first result only.

(Refer Slide Time: 43:06)

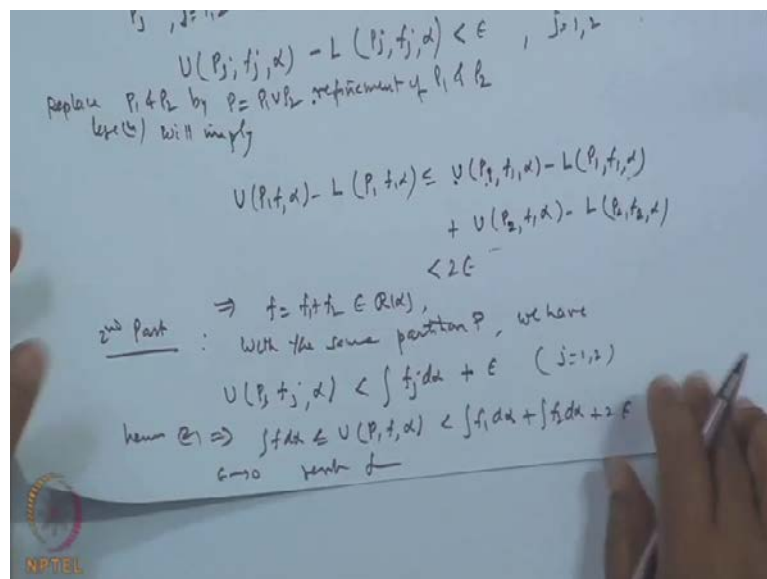

So, let's see the proof for first and rest will be. So, let f is f 1 plus f 2 and P is any partition. P is any partition of the interval a, b; any partition of a b then will we have, now let's see lower sum f lower sum of with respect to alpha over the partition P, is what

is basically the sigma small  $m_i \Delta \alpha_i$  is one to infinity. Where  $m_i$  is the infimum value of the function  $f(x)$ , over  $x$  lying between  $x_{i-1}$  to  $x_i$ . Now if I take the two function instead of  $f$  we take the  $f_1$  and  $f_2$  then what happen this and if  $f$  is the summation of if  $f$  is summation of  $f_1$  and  $f_2$  then the infimum value of  $m_i$  this will be greater than equal to the infimum of the function  $f_1(x)$ .

Over the same interval  $x_{i-1} < x < x_i$  plus infimum value of  $f_2(x)$  over the same interval  $x$  lying between  $x_{i-1}$  to  $x_i$  and the supremum will attain and supremum of this  $f(x)$  will be that is capital  $M_i$  will be less than equal to supremum of  $f_1(x)$  over same  $x$  over this interval plus supremum of  $f_2(x)$  supremum of  $f(x)$ , when  $x$  lies between  $x_{i-1}$  to  $x_i$ . So, supremum of the sum is less than equal to sum of the supremum and infimum will be greater.

So, that is what using this criteria we have now. The lower sum of  $P, f_1, \alpha$  plus lower sum of  $f_2$  with respect to  $\alpha$ , is less than equal to the lower sum of the function  $f$  with respect to because of this result, this result and which is a lower sum will always be less than the upper sum. So, we get this and then upper sum because of this it's again less than equal to what? Upper sum of  $P, f_1, \alpha$  plus upper sum of  $P, f_2, \alpha$  this now apply this condition.

(Refer Slide Time: 46:19)

So, let it be say four, now if  $f \in R(\alpha)$  since if  $f$  belongs to or  $f_1$  belongs to  $R(\alpha)$  and  $f_2$  also belongs to  $R(\alpha)$ . So, for a given epsilon we can find there are the partition by

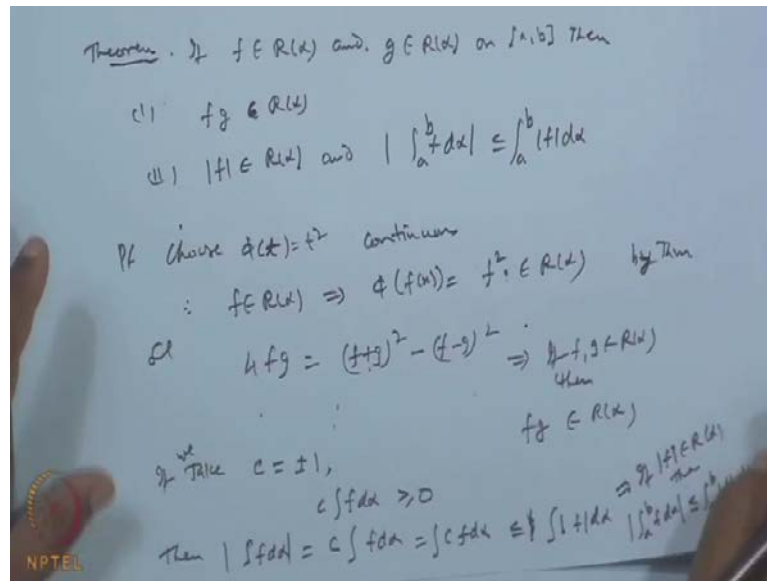

necessary and sufficient conditions are the partitions  $P_j$  where  $j$  is 1, 2,  $P_1$  and  $P_2$  respectively. Such that the upper sum of  $f_j$  with respect to  $\alpha$  over the partition  $P_j$  minus lower sum of  $f_j$  with respect to  $\alpha$  over the is less than  $\epsilon$  where  $j$  is 1, 2 this is by definition. So, use the now four use four. So, what you are getting is if we replace use four, replace  $P_1$  and  $P_2$  by  $P$  which is the union of this a refinement of  $P_1$  and  $P_2$  partition.

So, once we take this common partition then four will imply then four will imply will imply what? Upper sum minus the lower sum, what is the upper sum minus lower sum upper sum,  $P$   $\alpha$  minus upper sum minus lower sum is this, now upper sum in the first forth this is less than equal to this and lower sum is greater than. So, when you take the minus sign you will come you are coming like this. So, it is less than equal to upper sum of  $P_1$  this is  $P_1$   $P_1$   $f_1$   $\alpha$  minus lower sum  $P_1$ ,  $f_1$   $\alpha$  plus upper sum of  $P_2$ , I think this I did upper sum  $P$ , no this is upper sum of  $P$   $P_1$  is.

So, we are getting this part is  $P_1$   $\alpha$  and then here we are getting this is less than equal to what upper sum of  $P_2$ ,  $f_1$   $\alpha$  minus lower sum of  $P_2$ ,  $f_2$   $\alpha$ . From here just you get it like this what you are getting is the  $P_j$ . So, if I take this why it is so because upper sum decreases. So,  $P$  of this is less than sum of this lower sum increases. So, we are getting this one and this is less than  $\epsilon$  this is less than. So, this is less than  $2\epsilon$ , so we are getting this is less than which proves which implies that our  $f$  which if  $f_1$  plus  $f_2$  must be that all.

So, we get. So, this time we have this one therefore, and now for the integral part we can say for second part we say with the same partition  $P$  with the same partition  $P$ , we have we have the upper sum  $P$ ,  $f_j$ ,  $\alpha$  is strictly less than  $f_j$ ,  $d$   $\alpha$  plus  $\epsilon$  for  $j$  is 1, 2 and because this upper sum infimum value is this integral. So, we can get this thing. Hence the second implies this part hence will imply that  $\int f d\alpha$  is less than equal to  $U, P, f \alpha$  which is less than  $\int f_1 d\alpha$  plus  $\int f_2 d\alpha$  plus  $2\epsilon$  and  $\epsilon$  is arbitrary. So, the result follows.

(Refer Slide Time: 51:17)

So, this now another property is also which we just mentioned, if  $f$  is in  $R$  and  $g$  is also in  $R$  on the interval  $a, b$ , then the product of this is in  $R$  then second part is if  $f$  belongs to  $R$  and modulus of integral  $a$  to  $b$ ,  $f dx$  is less than equal to integral  $a$  to  $b$  modulus of  $f dx$  and less than equal to. The proof is based on the if  $\phi$  is a continuous function  $f$  is a Riemann Stieljes Integral. Then  $\phi \circ f$  will be a Riemann Integral, so depending on. So, choose  $\phi(x) = x^2$  which is continuous and therefore, if  $f$  is  $R$  then it implies that  $\phi \circ f$  that is the  $f^2$  must be in  $R$  by theorem previous. So, nothing similarly similarly what is  $4fg$ , this we can say  $(f+g)^2 - (f-g)^2$ .

Now this is integrable this is integrable belongs to. So, this belongs to. So, this implies if  $f$  and  $g$  both are in  $R$  then the product  $fg$  will also be in  $R$  because the constant times of this also in  $R$ . So, this implies then further if we take  $c$  as the plus minus one. So, we get what  $c \int f dx \geq 0$ . Suppose integral  $f dx$  is negative then take the  $c$  to be minus if it is positive then you take this one then modulus of integral  $f dx$  is equal to  $c \int f dx$ , because this is non-negative and then this is integral  $c f dx$  and this is less than equal to integral modulus of  $f dx$  because  $c$  is less than equal to 0. So, what we says is, so if our. So, this imply that if  $f$  belongs to  $R$  then the result hold this result that is integral modulus of integral  $a$  to  $b$   $f dx$  is less than or equal to integral  $a$  to  $b$  modulus of  $f dx$  holds and that is. Thank you very much.
