**Parametric Methods - IV**

So far, we have discussed the problem of estimation of parameters from the point of view of providing the point estimator for the; so by point estimator means that we assign a value as I was mentioning that or we have seen various examples like when we say we have a normal distribution with mean  $\mu$ , we consider  $\bar{x}$  as an estimator, so this is assigning a single value because based on a sample  $X_1, X_2, \dots, X_n$ ,  $\bar{x}$  will be 1 value.

But then there are some other concerns for example, this 1 value may be accurate or it may not be accurate because the true value is not known. Therefore, one consider providing a range of values in place of a single value that means, we consider an interval based on the sample and then we now, if we assign an interval then, certainly varies the probability associated with that interval and therefore we have a generalised concept, it is called confidence intervals.

**(Refer Slide Time: 01:24)**

Lecture - 12.

Interval Estimation  $(a, b) \rightarrow g(\theta)$

Confidence Intervals: Let  $X_1, \dots, X_n$  be a random sample from a population with distn  $P_\theta, \theta \in \Theta$ .  $\underline{X} = (X_1, \dots, X_n)$

Let  $T_1(\underline{X})$  &  $T_2(\underline{X})$  be two statistics such that

$$P_\theta(T_1(\underline{X}) \leq \theta \leq T_2(\underline{X})) = (1 - \alpha)$$

then  $(T_1(\underline{X}), T_2(\underline{X}))$  is  $100(1 - \alpha)\%$  confidence interval for  $\theta$  when  $\underline{X} = \underline{x}$  is observed.

Shortest Length Confidence Interval for fixed confidence coefficient.

Neyman-Pearson  
is optimal test

So, we consider say, interval estimation; in the interval estimation, we consider confidence intervals because we may assign an interval say  $a$  to  $b$  for estimating a certain parameter,  $g(\theta)$  but then, we have to qualify this interval by something for example, I may propose for average

longevity an interval of 55 to 65, somebody may propose 58 to 62 and so on. Therefore, to compare between various intervals, we need to introduce the concept of probability here.

So, now let us consider, so we have  $X_1, X_2, \dots, X_n$  a random sample from a population with distribution say  $P_\theta$ , where  $\theta$  belongs to  $\Theta$ . Then, let us consider say  $T_1(x)$  and  $T_2(x)$  be; here  $x$  is actually denoting the sample  $X_1, X_2, \dots, X_n$ ; let  $X_1, X_2, \dots, X_n$  be the random sample and we denote  $X_1, X_2, \dots, X_n$  and let  $T_1(x)$  and  $T_2(x)$  be 2 statistics such that probability of  $T_1(x) \leq \theta \leq T_2(x) = 1 - \alpha$ , then  $T_1(x)$  to  $T_2(x)$ , this is called under  $100(1 - \alpha)\%$  confidence interval for  $\theta$ , when  $x = x$  is observed.

So, basically it means that by the  $100(1 - \alpha)\%$  confidence, we will mean that if 100 times we do the sampling, then  $95\%$  of the time are under  $100(1 - \alpha)\%$  of the time, my true value is likely to lie in the interval  $T_1(x)$  to  $T_2(x)$ . So, now naturally your question is that how to find out this interval, so there are 2 optimality criteria for the confidence interval; one is shortest length confidence interval for fixed confidence coefficient, so this is called confidence coefficient.

So, that means if I fix this one, then what is the shortest interval which will have this probability  $1 - \alpha$  and another one is that for a fixed length, what could be the various functions for which I can have the minimum probability of coverage, so that is the minimum probability of coverage. So, Neyman; he related this problem of shortest length confidence interval to the optimal tests are the best tests for the hypothesis.

He connected this problem to optimal testing problems. Now, in this particular course, we will consider only the main problems of confidence interval estimation that means the problems related to normal distribution etc. Actually, the procedures which are developed here they are basically the best procedures or you can say shortest length procedures for phase confidence coefficient, however I will not be describing the full method for deriving this one.

**(Refer Slide Time: 06:15)**

Let  $X_1, \dots, X_n$  be a random sample from  $N(\mu, \sigma^2)$  population  
 We will find confidence interval for  $\mu$ .

Case I:  $\sigma^2$  is known.

Consider  $\bar{X} \sim N(\mu, \sigma^2/n) \Rightarrow \frac{\sqrt{n}(\bar{X}-\mu)}{\sigma} \sim N(0,1)$

$P(-z_{\alpha/2} \leq \frac{\sqrt{n}(\bar{X}-\mu)}{\sigma} \leq z_{\alpha/2}) = 1-\alpha \dots (1)$

where  $z_{\beta}$  is upper  $100\beta\%$  point of standard normal dist.  
 i.e.  $P(Z > z_{\beta}) = \beta, Z \sim N(0,1)$

From (1), we can deduce

$P(-\frac{\sigma}{\sqrt{n}} z_{\alpha/2} \leq \bar{X}-\mu \leq \frac{\sigma}{\sqrt{n}} z_{\alpha/2}) = 1-\alpha$

Rather, we will use a method called a method of pivoting for deriving the confidence intervals and you can see that this method is extremely simple; it is based on the sampling distributions that have been developed for the normal populations. So, let us consider say, let  $X_1, X_2, X_n$  be a random sample from normal  $\mu$   $\sigma^2$  population, okay. We will find confidence interval for  $\mu$ . Now, there can be 2 cases;  $\sigma^2$  is known.

In that case, this is a one parameter problem, if  $\sigma^2$  is known, let us consider  $\bar{x}$ , so  $\bar{x}$  follows normal  $\mu$   $\sigma^2/n$ , so we can construct a square root  $n(\bar{x} - \mu)/\sigma$  that follows normal 0,1. So, if we consider the normal curve here, a standard normal distribution, so we consider the  $z_{\alpha/2}$  and  $-z_{\alpha/2}$  that means this probability is  $\alpha/2$ , this probability is  $\alpha/2$ , so the middle probability is  $1-\alpha$ .

So, we can write down the statement; probability  $-z_{\alpha/2} \leq \frac{\sqrt{n}(\bar{x} - \mu)}{\sigma} \leq z_{\alpha/2}$  that is equal to  $1-\alpha$ , where by this  $z_{\beta}$ , denotes that is the upper  $100\beta\%$  point on standard normal curve that is probability of  $Z > z_{\beta} = \beta$ , if  $Z$  follows normal 0,1. So, now this statement let me call it 1, probability of  $-\frac{\sigma}{\sqrt{n}} z_{\alpha/2} \leq \bar{x} - \mu \leq \frac{\sigma}{\sqrt{n}} z_{\alpha/2}$  that is =  $1-\alpha$ .

**(Refer Slide Time: 09:03)**

© CEE 11.7.2018 (3)

$$\Rightarrow P\left(\bar{X} - \frac{\sigma}{\sqrt{n}} z_{\alpha/2} \leq \mu \leq \bar{X} + \frac{\sigma}{\sqrt{n}} z_{\alpha/2}\right) = 1 - \alpha$$

So  $\left(\bar{X} - \frac{\sigma}{\sqrt{n}} z_{\alpha/2}, \bar{X} + \frac{\sigma}{\sqrt{n}} z_{\alpha/2}\right)$  is 100(1- $\alpha$ )% confidence interval for  $\mu$ .

Case II:  $\sigma^2$  is unknown

$$S^2 = \frac{1}{n-1} \sum (X_i - \bar{X})^2, \quad \frac{(n-1)S^2}{\sigma^2} \sim \chi_{n-1}^2$$

Also  $\bar{X}$  &  $S^2$  are independently distributed.

$$\text{So } \frac{\frac{\sqrt{n}(\bar{X} - \mu)}{\sigma}}{\frac{\sqrt{(n-1)S^2}}{\sigma^2(n-1)}} = \frac{\sqrt{n}(\bar{X} - \mu)}{S} \sim t_{n-1}.$$

Now, this can be further written as probability of  $\bar{x} - \sigma/\sqrt{n} z_{\alpha/2} \leq \mu \leq \bar{x} + \sigma/\sqrt{n} z_{\alpha/2} = 1 - \alpha$ . So, if we compare this statement with probability of  $T1x \leq \theta \leq T2x = 1 - \alpha$ , then you can see that this  $\bar{x} - \sigma/\sqrt{n} z_{\alpha/2}$  acts as  $T1x$  and  $\bar{x} + \sigma/\sqrt{n} z_{\alpha/2}$  acts as  $T2x$  that means you have the confidence limits for the mean of the normal distribution.

So,  $\bar{x} - \sigma/\sqrt{n} z_{\alpha/2}$  to  $\bar{x} + \sigma/\sqrt{n} z_{\alpha/2}$ , so in place of capital  $X$  bar, you put small  $x$  bar, that will become the observed confidence interval is 100(1- $\alpha$ )% confidence interval for  $\mu$ . Now, in this case, it may happen that  $\sigma$  is unknown, if  $\sigma$  is unknown, then I cannot make use of this confidence limits. So, in this case we consider a  $S$  square also.

So, then take; if you remember in the case of sampling distributions, I introduced the distribution of  $S$  square, so if I am taking say,  $S$  square as  $1/(n-1) \sum (x_i - \bar{x})^2$ , then  $(n-1) S^2 / \sigma^2$  follows chi square distribution on  $n-1$  degrees of freedom. Also,  $\bar{X}$  and  $S$  square are independently distributed, so if we consider a square root  $n (\bar{X} - \mu) / \sigma$  divided by a square root  $(n-1) S^2 / \sigma^2$  that is equal to  $\sqrt{n} (\bar{X} - \mu) / S$  that has  $t$  distribution on  $n-1$  degrees of freedom.

**(Refer Slide Time: 12:00)**

$\sigma$  is unknown

$$S^2 = \frac{1}{n-1} \sum (X_i - \bar{X})^2, \quad \frac{(n-1)S^2}{\sigma^2} \sim \chi_{n-1}^2$$

$\bar{X}$  &  $S^2$  are independently distributed.

$$\frac{(\bar{X} - \mu)}{\frac{S}{\sqrt{n}}} = \frac{\sqrt{n}(\bar{X} - \mu)}{S} \sim t_{n-1}$$

Now, if you look at the nature of the t distributions frequency function, then this is also symmetric and if you consider the  $t_{n-1, \alpha/2}$  and on this side, we take  $-t_{n-1, \alpha/2}$ , then this probability is  $1 - \alpha$ .

**(Refer Slide Time: 12:33)**

We can then write  $P\left(-t_{n-1, \frac{\alpha}{2}} \leq \frac{\sqrt{n}(\bar{X} - \mu)}{S} \leq t_{n-1, \frac{\alpha}{2}}\right) = 1 - \alpha$

$$\Leftrightarrow P\left(-\frac{S}{\sqrt{n}} t_{n-1, \frac{\alpha}{2}} \leq \bar{X} - \mu \leq \frac{S}{\sqrt{n}} t_{n-1, \frac{\alpha}{2}}\right) = 1 - \alpha$$

$$\Rightarrow P\left(\bar{X} - \frac{S}{\sqrt{n}} t_{n-1, \frac{\alpha}{2}} \leq \mu \leq \bar{X} + \frac{S}{\sqrt{n}} t_{n-1, \frac{\alpha}{2}}\right) = 1 - \alpha$$

$\therefore \left(\bar{X} - \frac{S}{\sqrt{n}} t_{n-1, \frac{\alpha}{2}}, \bar{X} + \frac{S}{\sqrt{n}} t_{n-1, \frac{\alpha}{2}}\right)$  is  $100(1 - \alpha)\%$  confidence interval for  $\mu$ .

Confidence Interval for  $\sigma^2$  :  $X_1, \dots, X_n \sim N(\mu, \sigma^2)$

Case I :  $\mu$  is known  $Y_i = \frac{X_i - \mu}{\sigma} \sim N(0, 1)$

$$\sum Y_i^2 = \frac{\sum (X_i - \mu)^2}{\sigma^2} \sim \chi_n^2$$

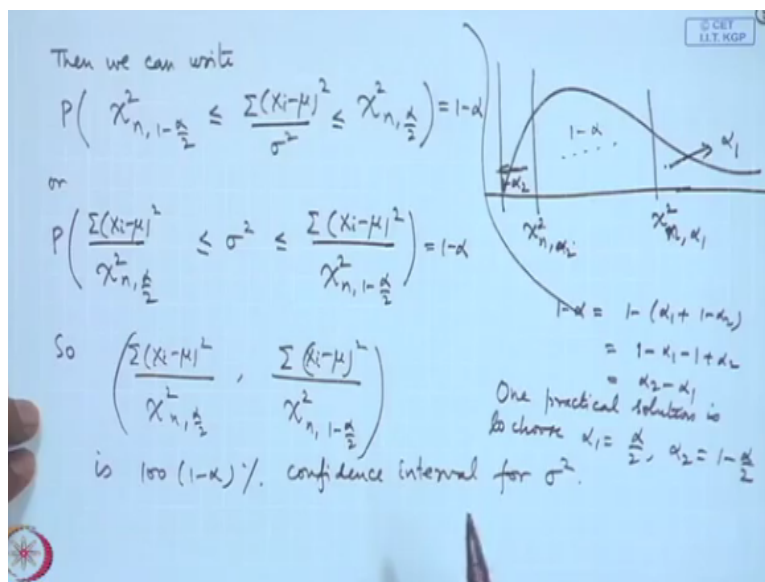

$Y_1, \dots, Y_n$  i.i.d.  $N(0, 1)$

So, we can construct the confidence interval using this here we have; we can then write probability of  $-t_{n-1, \alpha/2} \leq \frac{\sqrt{n} \bar{X} - \mu}{S} \leq t_{n-1, \alpha/2}$  that is  $= 1 - \alpha$ . So, now as in the previous case, you can manipulate this to get  $-\frac{S}{\sqrt{n}} t_{n-1, \alpha/2} \leq \bar{X} - \mu \leq \frac{S}{\sqrt{n}} t_{n-1, \alpha/2} = 1 - \alpha$  or probability of  $\bar{X} - \frac{S}{\sqrt{n}} t_{n-1, \alpha/2} \leq \bar{X} + \frac{S}{\sqrt{n}} t_{n-1, \alpha/2} \leq \mu, \leq$  this is  $= 1 - \alpha$ .

So,  $\bar{X} - S/\sqrt{n} t_{n-1, \alpha/2}$ ,  $2\bar{X} + S/\sqrt{n} t_{n-1, \alpha/2}$ , this is  $100(1-\alpha)\%$  confidence interval for  $\mu$ . In a similar way, we can obtain the confidence intervals for sigma square also. In this case, again I consider 2 cases; case 1, when  $\mu$  is known, now if I am considering  $X_1, X_2, \dots, X_n$  following normal  $\mu, \sigma^2$ , then by the linearity property you are having; suppose, I consider  $Y_i = (X_i - \mu)/\sigma$  and that follows normal  $0, 1$ .

So,  $Y_1, Y_2, \dots, Y_n$  are independent and identically distributed normal  $0, 1$  random variables. So, if I consider  $\sum Y_i^2$  that is  $\sum (X_i - \mu)^2 / \sigma^2$  that follows chi square distribution on  $N$  degrees of freedom. So you can see this, here I am;  $\mu$  is known, so the numerator is known quantity and this is involving the parameter sigma square for which the confidence interval is required.

**(Refer Slide Time: 15:49)**

So, if you look at the nature of the PDF of chi square distribution, so if you consider 2 limits, now there is a difference from the TN normal distributions, they were symmetric distribution. In the case of chi square, they are not, so we may consider in fact, 2 points. Suppose, I take this probability as equal to alpha 1, say chi square n alpha 1 and on this side, I will take chi square n and this probability I take to be alpha 2, so I take 1- alpha 2 for example.

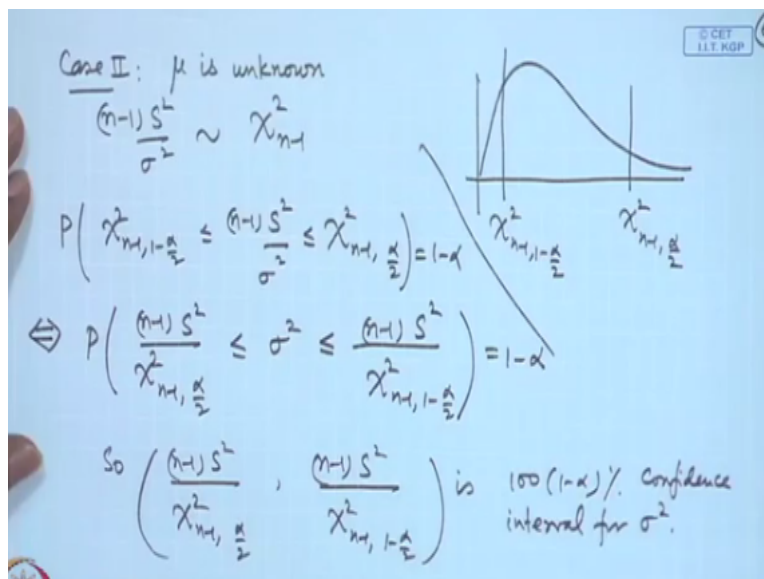

So, this is becoming 1-alpha 2, then in between this is 1-alpha that means I am considering  $1 - \alpha = 1 - \alpha_1 + 1 - \alpha_2$  that is  $= 1 - \alpha_1 - 1 + \alpha_2$  that is  $= \alpha_2 - \alpha_1$ .

So, one practical solution is; one practical solution is to choose  $\alpha_1 = \alpha/2$  and  $\alpha_2 = 1 - \alpha/2$ . In that case, you can see here that this will contain  $1 - \alpha$  here. So, because there can be many solutions here.

Whereas, in the case of confidence interval for  $\mu$ , we had the shortest length but here shortest length is not ensured, so you can actually choose many different choices but a practical solution could be this. This is also do take care of the usage of various and the probability tables related to chi square distribution because the percentage points of chi square are tabulated. So, if you have to make use of that, then this is much better solution.

So, then we can write probability of chi square  $n - 1 - \alpha/2 \leq \sum (X_i - \mu)^2 / \sigma^2 \leq \chi^2_{n, \alpha/2} = 1 - \alpha$ . So, this is equivalent to probability of sigma square being  $\geq \sum (X_i - \mu)^2 / \chi^2_{n, \alpha/2}$  and  $\leq \sum (X_i - \mu)^2 / \chi^2_{n, 1 - \alpha/2}$ , this is  $100 - (1 - \alpha) \%$  confidence interval for sigma square.

**(Refer Slide Time: 19:53)**

This is the case, when  $\mu$  is known but if  $\mu$  is unknown, then we cannot use this and then we make use of  $S$  square. We consider the case, when  $\mu$  is unknown; in the case of  $\mu$  is unknown, we consider  $n - 1 S$  square/ sigma square that is following chi square distribution on  $n$

-1 degrees of freedom. So, in place of; so now I consider chi square  $n - 1$   $\alpha/2$  and chi square  $n - 1$ ,  $1 - \alpha/2$ .

So, we have the probability of chi square  $n - 1$   $1 - \alpha/2 \leq n - 1 S^2 / \sigma^2 \leq$  chi square  $n - 1$   $\alpha/2$  that is  $= 1 - \alpha$ , so arguing as before, this is equivalent to probability of  $n - 1 S^2 / \chi^2_{n - 1, \alpha/2} \leq \sigma^2 \leq n - 1 S^2 / \chi^2_{n - 1, 1 - \alpha/2}$  this is  $= 1 - \alpha$ . So, the confidence limits for sigma square in this case turn out to be that is  $n - 1 S^2 / \chi^2_{n - 1, \alpha/2}$  to  $n - 1 S^2 / \chi^2_{n - 1, 1 - \alpha/2}$ .

**(Refer Slide Time: 21:59)**

Example: Suppose the data is recorded as 140, 136, 150, 144, 148, 152, 138, 141, 143, 151 ( $n = 10$ ) from  $N(\mu, \sigma^2)$  pop<sup>n</sup>.

$S^2 = 32.23$ ,  $\chi^2_{9, 0.005} = 23.59$   $\alpha = 0.01$

$\chi^2_{9, 0.995} = 1.73$ .

$\left( \frac{(n-1)S^2}{\chi^2_{n-1, 0.005}}, \frac{(n-1)S^2}{\chi^2_{n-1, 0.995}} \right) \equiv (12.30, 167.21)$

99% confidence interval for  $\sigma^2$ .

So, this is  $100(1 - \alpha)$  % confidence interval for sigma square. Let us take 1 example here, suppose we are having the battery capacity is; so, suppose the data is recorded as say, 140, 136, 150, 144, 148, 152, 138, 141, 143, 151 that is  $n = 10$  here from normal  $\mu$  sigma square population, okay. Let us calculate a confidence interval for sigma square in this particular problem.

So, we can check here,  $S^2$  turns out to be 32.23 and we will need chi square  $n$ , suppose I take  $\alpha = 0.01$ , so I will need chi square on 9 degrees of freedom 0.005, so from the tables of chi square distribution, we can check this point is 23.59 and chi square 9, 0.995 that is  $= 1.73$ , so we can calculate here  $n - 1 S^2 / \chi^2_{n - 1, 0.005}$   $n - 1 S^2 / \chi^2_{n - 1, 0.995}$ , so you can check that this is  $= 12.30$  to 167.21.

So, these are the confidence limits for sigma square, so this is 99% confidence interval for sigma square. Now, this is about one sample problems, when the underlying population we have taken to the normal distribution. Actually, this method that I have shown here is actually applicable to other distributions also, basically we are constructing a function, whose distribution turns out to be independent of the parameter and the function itself includes the observations as well as the parameter of interest.

(Refer Slide Time: 25:13)

Non-normal Populations  
 $X_1, \dots, X_n$  is a random sample from  $U[0, \theta]$ .  
 $X_{(n)} \quad Y = \frac{X_{(n)}}{\theta}$   
 Then pdf of  $Y$  is  $f(y) = ny^{n-1}, 0 < y < 1$   
 $= 0, \text{ else}$   
 Let  $g_1(x) \leq g_2(x)$  be  $\Rightarrow$   
 $P(g_1(x) < Y < g_2(x)) = 1 - \alpha$   
 or  $g_2^n(x) - g_1^n(x) = 1 - \alpha$ .  
 Choose  $g_2 = 1, g_1 = \alpha^{1/n}$ . Then  
 $P(\alpha^{1/n} < \frac{X_{(n)}}{\theta} < 1) = 1 - \alpha \Leftrightarrow P(X_{(n)} < \theta < \frac{X_{(n)}}{\alpha^{1/n}}) = 1 - \alpha$   
 So  $100(1 - \alpha)\%$  confidence interval for  $\theta$  is  $(X_{(n)}, \alpha^{-1/n} X_{(n)})$ .

If we are using both of this, then we are able to get the confidence interval easily, this is called the method of pivoting. Let me give an application where we are dealing with some non-normal population. Let us consider say, non-normal population suppose,  $x_1, x_2, x_n$  is a random sample from uniform distribution on the interval say 0 to theta. Now, we can actually consider the confidence interval in various ways but I will consider the sufficient statistics.

So,  $X_n$  is a sufficient statistics and we know the distribution of  $X_n$  in fact, in the previous lecture, I have given the form of the distribution of this one. Let us consider say,  $Y = X_n / \theta$ , then the probability density function of  $Y$  is given by  $f_Y = n y^{n-1}$  for  $Y$  lie between 0 to 1. Now, let us choose say, 2 points let me call it say,  $g_1 \alpha$  and  $g_2 \alpha$ , the probability of  $g_1 \alpha < Y < g_2 \alpha$  be  $= 1 - \alpha$ .

Since, here the integral will give you Y to be power n, this is becoming equivalent to  $g_2$  to the power  $n \alpha - g_1$  to the power  $n \alpha = 1 - \alpha$ . So, if we chose, say  $g_2 = 1$  and say,  $g_1 = \alpha$  to the power  $1/n$ , then we are getting probability of  $\alpha$  to the  $1/n < X_n/\theta < 1 = 1 - \alpha$ , which is equivalent to same probability of  $\theta > X_n < X_n$  divided by  $\alpha$  to the power  $1/n = 1 - \alpha$ .

So,  $100(1 - \alpha)$  % confidence interval for  $\theta$  is  $X_n, \alpha$  to the power  $-1/n$   $X_n$ . Of course, you can see that this choice is quite arbitrary here that I have taken for  $g_1$  and  $g_2$ , we may take in some other way also, so that this probability is  $1 - \alpha$  and that would lead to different confidence intervals but all of them will have the confidence coefficient =  $1 - \alpha$ . Let me take one more example of the non-normal population.

**(Refer Slide Time: 28:18)**

2.  $X_1, \dots, X_n$  be a random sample from  $\text{Exp}(\lambda)$   
 $f(x, \lambda) = \lambda e^{-\lambda x}, x > 0$   
 $Y = \sum X_i \sim \text{Gamma}(n, \lambda)$   
 $f(y) = \frac{\lambda^n}{\Gamma(n)} e^{-\lambda y} y^{n-1}, y > 0$   
 Define  $W = 2\lambda Y$   $\rightarrow$   $f(w) = \frac{\lambda^n}{\Gamma(n)} e^{-\frac{w}{2}} \left(\frac{w}{2\lambda}\right)^{n-1} \cdot \frac{1}{2\lambda}$   
 $= \frac{1}{2^n \Gamma(n)} e^{-w/2} w^{n-1}, w > 0$   
 $= \frac{1}{2^{\frac{2n}{2}} \frac{\Gamma(\frac{2n}{2})}{2}} e^{-\frac{w}{2}} w^{\frac{2n}{2}-1}, w > 0$   
 So  $W \sim \chi_{2n}^2$

Say, let  $X_1, X_2, \dots, X_n$  be a random sample from say, exponential distribution; exponential  $\lambda$  that means I am considering the probability density function to be  $\lambda e^{-\lambda x}$ . Now, if you consider the sufficiency, then  $\sum X_i$  that is equal to say  $Y$ , that is having gamma distribution with parameter  $n$  and  $\lambda$ . Now, if you write down the density of this and we make function of this, let us consider that.

If I consider the density of  $y$  that is equal to  $\lambda^n$  to the power  $n$  divided by  $\Gamma(n)$   $e^{-\lambda y}$ ,  $y$  to the power  $n-1$ . I define  $2\lambda y =$  say,  $W$ . Now, what is the density

of  $W$ ? Then, that is  $\lambda$  to the power  $n/\gamma$  and  $e$  to the power  $-W/2$ ,  $W/2 \lambda$  to the power  $n - 1/2 \lambda$  that is equal to; so here  $\lambda$  to the power  $n$  cancels out and you get  $1/2$  to the power  $n$   $\gamma^n e$  to the power  $-W/2$ ,  $W$  to the power  $n - 1$  for  $W > 0$ .

We can be represented in this form;  $1/2$  to the power  $2n/2$   $\gamma^{2n/2} e$  to the power  $-W/2$ ,  $W$  to the power  $2n/2 - 1$ , for  $W > 0$ . So, what we have proved that  $W$  is actually chi square distribution on  $2n$  degrees of freedom. Now, you can see again we can make use of  $W$  because  $W$  involves the observations in the form of  $Y$  here;  $Y = \sum X_i$  and we are; it is also involved in the parameter of interest.

**(Refer Slide Time: 30:52)**

So, we can consider of the confidence interval for  $\lambda$  for  $1/\lambda$  etc., by making use of this chi square distribution on  $2n$  degree of freedom and once again for convenience, we may take  $\chi^2_{2n, \alpha/2}$  and  $\chi^2_{2n, 1-\alpha/2}$ , so that this probability is  $1-\alpha$ .

**(Refer Slide Time: 31:18)**

$$P\left(\chi_{2n, 1-\frac{\alpha}{2}}^2 \leq W \leq \chi_{2n, \frac{\alpha}{2}}^2\right) = 1-\alpha$$

$$\Leftrightarrow P\left(\chi_{2n, 1-\frac{\alpha}{2}}^2 \leq 2\lambda Y \leq \chi_{2n, \frac{\alpha}{2}}^2\right) = 1-\alpha$$

$$\Leftrightarrow P\left(\frac{\chi_{2n, 1-\frac{\alpha}{2}}^2}{2Y} \leq \lambda \leq \frac{\chi_{2n, \frac{\alpha}{2}}^2}{2Y}\right) = 1-\alpha$$

Also

$$P\left(\frac{2Y}{\chi_{2n, \frac{\alpha}{2}}^2} \leq \frac{1}{\lambda} \leq \frac{2Y}{\chi_{2n, 1-\frac{\alpha}{2}}^2}\right) = 1-\alpha$$

So, you get probability of chi square  $2n$   $1-\alpha/2 \leq W, \leq$  chi square  $2n$   $\alpha/2 = 1-\alpha$ , so this is equivalent to probability of chi square  $2n$   $1-\alpha/2 \leq 2\lambda Y, \leq$  chi square  $2n$   $\alpha/2$ , so for lambda, we get chi square  $2n$   $1-\alpha/2 / 2Y$ , also if you want for  $1/\lambda$ , then you can consider the reciprocal here;  $1/\lambda$  is between  $2Y / \chi^2_{2n, 1-\alpha/2}$   $2Y / \chi^2_{2n, \alpha/2}$  that is equal to  $1-\alpha$ .

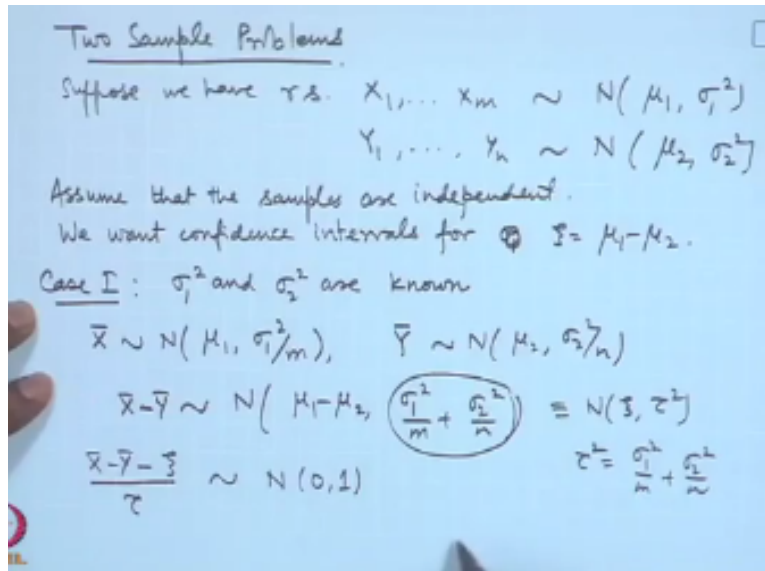

So, confidence intervals for lambda as well as  $1/\lambda$  can be obtained in in the terms of the sigma Xi and the percentage points of the chi square distribution on  $2n$  degrees of freedom. So, this pivoting method is extremely a practical method for obtaining the confidence intervals for various distributions. Here, I have considered 1 sample problems, now there are many situations where we are dealing with 2 populations.

And our interest is to compare the; say, for example means of the 2 populations, you can think of say, average income level of 2 different countries, which I call them  $\mu_1$  and  $\mu_2$ . Now, I look at the difference, if I want to compare  $\mu_1$  and  $\mu_2$ , then a simple measure is  $\mu_1 - \mu_2$  and therefore we would like to estimate  $\mu_1 - \mu_2$  and we may require the confidence intervals for  $\mu_1 - \mu_2$ .

Similarly, we may consider say variability; for example, there are 2 different instruments for measuring something, now if you are measuring something, then the mean is the same but

variability may be different because the precision of the 2 machines may be different depending upon their makeup, now if the makes are quite different, then sigma 1 square and sigma 2 square may be different and we would like to consider the relative precision.

**(Refer Slide Time: 34:28)**

For example, what is sigma 1 square/ sigma 2 square and therefore we would like to set up confidence interval for the ratio of the variances. So, let us consider these 2 sample problems related to normal populations. Suppose we have a random sample say, X1, X2, Xn from normal Mu 1 sigma 1 square and Y1, Y2, Yn, say this is a random sample from normal Mu 2, sigma 2 square.

And we assume that the samples are independent, if we assume that samples are independent, we want confidence intervals for sigma one; for say, let me write it say Xi = Mu 1 – Mu 2. Then, let us consider the different possibilities. First case is that sigma 1 square and sigma 2 square are known, so in this case we consider, say X bar following normal Mu 1 sigma 1 square/ n and Y were follows; normal Mu 2 sigma 2 square/n.

Then, if you look at the difference, then X bar - Y bar this will follow normal Mu 1- Mu 2 sigma 1 square/ m + sigma 2 square/ n, so X bar minus - Y bar – Xi, where this Xi is denoting Mu 1- Mu 2 divided by this quantity, let us call it normal Xi tau square. So, this tau square is nothing

but  $\sigma_1^2/m + \sigma_2^2/n$ , so this divided by  $\tau$  that will follow normal 0, 1.  
 So, once again now we can use this as a pivoting quantity.

**(Refer Slide Time: 37:22)**

And we can look at the standard normal curve, so  $z_{\alpha/2}$  and  $-z_{\alpha/2}$ , so that this probability is  $1-\alpha$  here.

**(Refer Slide Time: 37:40)**

To construct the confidence interval for  $\xi$ , we consider

$$P\left(-z_{\alpha/2} \leq \frac{\bar{X}-\bar{Y}-\xi}{\tau} \leq z_{\alpha/2}\right) = 1-\alpha$$

or

$$P\left(\bar{X}-\bar{Y}-\tau z_{\alpha/2} \leq \xi \leq \bar{X}-\bar{Y}+\tau z_{\alpha/2}\right) = 1-\alpha$$

So confidence limits are  $\bar{X}-\bar{Y} \pm \tau z_{\alpha/2}$  for  $\mu_1-\mu_2$ .

Case II :  $\sigma_1^2$  &  $\sigma_2^2$  are unknown,  $\sigma_1^2 = \sigma_2^2 = \sigma^2$  say

$$\bar{X}-\bar{Y} \sim N\left(\xi, \sigma^2\left(\frac{1}{m}+\frac{1}{n}\right)\right) = N\left(\xi, \sigma^2\left(\frac{m+n}{mn}\right)\right)$$

$$\frac{\sqrt{\frac{mn}{m+n}}(\bar{X}-\bar{Y}-\xi)}{\sigma} \sim N(0,1)$$

So, to construct the confidence interval for  $\xi$ , we consider then probability of  $-z_{\alpha/2} \leq \frac{\bar{X}-\bar{Y}-\xi}{\tau} \leq z_{\alpha/2}$  that =  $1-\alpha$ , which is equivalent to same  $\bar{X}-\bar{Y}$  minus  $-\tau z_{\alpha/2} \leq \xi \leq \bar{X}-\bar{Y}+\tau z_{\alpha/2}$  that is equal to  $1-\alpha$ , so

confidence limits are  $\bar{X} - \bar{Y} \pm \tau z_{\alpha/2}$  for  $\mu_1 - \mu_2$ . Naturally, when  $\sigma_1^2$  and  $\sigma_2^2$  are not known, then I cannot make use of this  $\tau$  here.

Because  $\tau$  is involving  $\sigma_1^2$  and  $\sigma_2^2$ , so let us consider the case when  $\sigma_1^2$  and  $\sigma_2^2$  are unknown but here again, there are 2 possibilities. They may be unknown but equal or there may be totally known, they may be totally unequal. So, we can consider these 2 cases separately, so let us take  $\sigma_1^2 = \sigma_2^2$ . Now, in this case, the first term that will happen that is  $\bar{X} - \bar{Y}$  that was following normal  $X_i$ .

**(Refer Slide Time: 40:31)**

So confidence limits are  $\bar{X} - \bar{Y} \pm \tau z_{\alpha/2}$  for  $\mu_1 - \mu_2$ .

Case II:  $\sigma_1^2$  &  $\sigma_2^2$  are unknown,  $\sigma_1^2 = \sigma_2^2 = \sigma^2$  say

$$\bar{X} - \bar{Y} \sim N(\xi, \sigma^2 \left(\frac{1}{m} + \frac{1}{n}\right)) = N(\xi, \sigma^2 \left(\frac{m+n}{mn}\right))$$

$$\sqrt{\frac{m+n}{mn}} \frac{(\bar{X} - \bar{Y} - \xi)}{\sigma} \sim N(0, 1)$$

Let  $S_1^2 = \frac{1}{m-1} \sum (X_i - \bar{X})^2$ ,  $S_2^2 = \frac{1}{n-1} \sum (Y_j - \bar{Y})^2$

And this  $\tau^2$  will become  $\sigma^2 * (1/m + 1/n)$  that is nothing but normal  $X_i$   $\sigma^2$   $(m + n) / mn$ , so  $\bar{X} - \bar{Y} - \xi / \sigma \sqrt{(m+n)/mn}$ , that is following normal 0,1 distributions. Now, we also consider the sample variances, let us defined say,  $S_1^2 = 1/(m-1) \sum (X_i - \bar{X})^2$  and  $S_2^2 = 1/(n-1) \sum (Y_j - \bar{Y})^2$ , so these are the sample variances from the 2 populations.

**(Refer Slide Time: 41:08)**

$$\frac{(m-1)S_1^2}{\sigma^2} \sim \chi_{m-1}^2, \quad \frac{(n-1)S_2^2}{\sigma^2} \sim \chi_{n-1}^2$$

$$\Rightarrow \frac{(m-1)S_1^2 + (n-1)S_2^2}{\sigma^2} \sim \chi_{m+n-2}^2$$
 Define  $S_p^2 = \frac{(m-1)S_1^2 + (n-1)S_2^2}{m+n-2}$  → pooled sample variance  

$$\text{Soln} = \frac{(m+n-2)S_p^2}{\sigma^2} \sim \chi_{m+n-2}^2$$

$$\bar{X} \text{ \& } W \text{ are independently distributed. So we can construct}$$

$$\frac{\bar{Z}}{\sqrt{\frac{W}{m+n-2}}} = \sqrt{\frac{mn}{m+n}} \left( \frac{\bar{X} - \bar{Y} - \xi}{S_p} \right) \sim t_{m+n-2}$$

Now, we look at the distributions of S1 square and S2 square, since we know that in the sampling from normal populations, the sample variance has chi square distribution, we get m -1 S1 square/ sigma square that will follow chi square distribution on m -1 degrees of freedom, n-1 -1 S2 square/ sigma square that will follow chi square distribution on n -1 degree of freedom. Also, since the 2 samples are taken to be independent, S1 square and S2 square are independent.

As a consequence, I can use the additive property of the chi square distribution and we will get m-1 S1 square + n -1 S2 square divided by sigma Square following chi square m + n-2, so we define Sp square = m -1 S1 square + n -1 S2 square/ m + n -2 that is the pooled sample variance, so you have basically m + n -2 Sp square/ sigma square following chi square distribution on m + n-2 degrees of freedom.

Now, in the sampling from normal populations, sample means and the sample variances are independently distributed. Therefore, if we consider square root mn/ m + n X bar – Y bar – Xi / sigma; the distribution is independent of the distribution of m + n -2 Sp square/ sigma square, so I can write the ratio; we have, let us give them some names, so I call this Z and that this one I call say W.

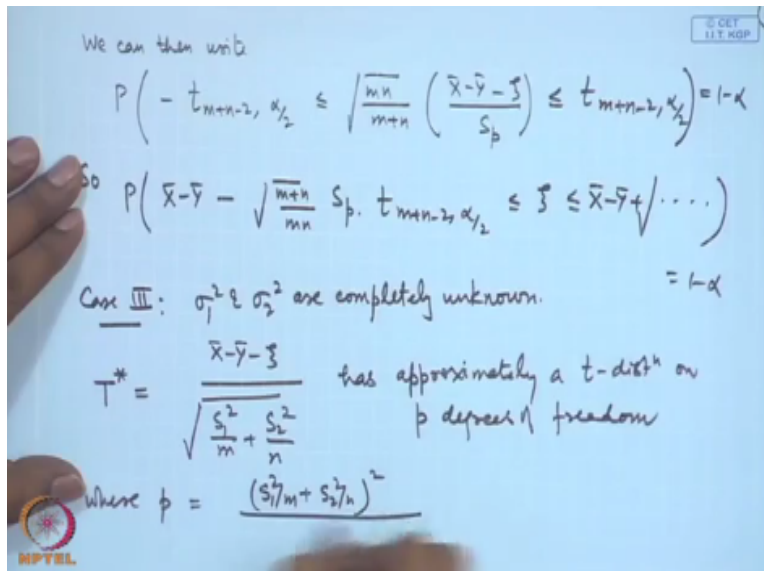

**(Refer Slide Time: 44:18)**

So, Z and W are independent, so we can construct Z divided by the square root W/ m + n -2, so that is becoming X bar - Y bar - Xi / the Sp root mn/m +n, then this will follow t distribution on m+n-2 degrees of freedom. Once again, now we can use the form of the PDF of t distribution and easily we can construct the confidence interval for Xi, so this probability is 1- alpha.

**(Refer Slide Time: 44:39)**

And we can then write probability of  $-t_{m+n-2, \alpha/2}$ , so the confidence limits turn out to be probability of  $X \text{ bar} - Y \text{ bar} - \sqrt{m+n/mn} S_p t_{m+n-2, \alpha/2}$ ,  $X \text{ bar} - Y \text{ bar} +$  same quantity here that is  $= 1- \alpha$ . So, we are able to set up the confidence limits for  $\mu_1 - \mu_2$ , now this is under the assumption that the variances of the 2 normal populations are unknown but equal. Now, this is facilitated actually in the; using additive property of the chi square distribution.

Because I was able to add the 2 terms, now if they are not equal then sigma 1 square and sigma 2 square will come in these 2 terms and I cannot add it here, because adding will not pool, I will be getting separate term that is m -1 S1 square/ sigma 1 square + n-1 S2 square/ sigma 2 square, so this cancellation that has happened by taking the ratio of sigma that will not take place. Now, therefore this problem becomes a little complicated.

In fact, we do not have an exact confidence interval in the sense that we have here the best solution, so we have an approximate solution let me call it say, case 3; sigma 1 square and sigma 2 square are say, completely unknown. In that case, another statistical, let us call it say, T star that is  $\bar{X} - \bar{Y} - \mu$  / square root S1 square/ M + S2 square/ n, this has approximately t distribution on; say, p degrees of freedom.

**(Refer Slide Time: 47:49)**

Case III:  $\sigma_1^2$  &  $\sigma_2^2$  are completely unknown.  $= 1-\alpha$

$$T^* = \frac{\bar{X} - \bar{Y} - \mu}{\sqrt{\frac{S_1^2}{m} + \frac{S_2^2}{n}}}$$

has approximately a t-dist<sup>n</sup> on p degrees of freedom

$$\text{where } p = \frac{(S_1^2/m + S_2^2/n)^2}{\left\{ \frac{S_1^4}{m^2(m-1)} + \frac{S_2^4}{n^2(n-1)} \right\}}$$

(where we take integral part of the terms on the right side)

Welch-Satterthwaite

And where this p is approximately equal to S1 square/m + S2 square/ n whole square divided by S1 to the power 4/ m square \* m-1+ S2 to the power 4 divided by n square \* n-1. Now, naturally this is not an integer, so we consider the integral part of it, where we take integral part of the term on the right side. So, this is an approximate test and it was developed by Welch and also Smith Satterthwaite.

**(Refer Slide Time: 48:46)**

Based on  $T^*$  we get confidence limits for  $\bar{z}$  as

$$\bar{X} - \bar{Y} \pm \sqrt{\frac{S_1^2}{m} + \frac{S_2^2}{n}} t_{p, \frac{\alpha}{2}}$$

Case IV: Paired Observations

$$\begin{pmatrix} X_1 \\ Y_1 \end{pmatrix}, \begin{pmatrix} X_2 \\ Y_2 \end{pmatrix}, \dots, \begin{pmatrix} X_n \\ Y_n \end{pmatrix} \sim \text{BVN} \left( \begin{pmatrix} \mu_1 \\ \mu_2 \end{pmatrix}, \begin{pmatrix} \sigma_1^2 & \rho\sigma_1\sigma_2 \\ \rho\sigma_1\sigma_2 & \sigma_2^2 \end{pmatrix} \right)$$

Blood sugar level before the treatment X  
 . . . . . after the treatment Y

Patients	1	2	3	...	n
X :	$X_1$	$X_2$	.	.	$X_n$
Y :	$Y_1$	$Y_2$	.	.	$Y_n$

So, based on this again, we can construct a confidence interval based on T star, we get confidence limits for  $X_i$  as  $\bar{X} - \bar{Y} \pm \sqrt{S_1^2/m + S_2^2/n} t_{p, \alpha/2}$ . There is another case, in this all the cases we have considered the sampling to be independent but there are also situations, where the sampling may not be or you cannot assume that the 2 samples are independent.

Consider for example, effect of a medicine for a say, patients who have diabetes, now the sugar levels were measured before they started the treatment. Suppose, after taking the medicine for a month, again their blood sugar levels are measured, suppose there are say, 10 patients, now blood sugar patient of; blood sugar level of patient 1 will be related to his blood sugar level after taking the treatment.

Similarly, for patient number 2; similarly, for patient number 3, that means here we can consider the observations to be in some sense, paired observations, I call it case 4; paired observations that means I am considering here something like  $X_1, Y_1, X_2, Y_2$  and so on  $X_n, Y_n$ , so we are assuming basically bivariate normal model with mean  $\mu_1, \mu_2$  and variance covariance matrices;  $\sigma_1^2, \sigma_2^2, \rho\sigma_1, \rho\sigma_2$ ;  $\rho\sigma_1, \sigma_2$ .

Basically, it is something like this, I have given the example of say, blood sugar level okay before the treatment and blood sugar level after the treatment, so this is say X; this is Y, so the

data will be on patients 1, 2, 3 up to n and here X values will be  $X_1, X_2$  and so on  $X_n$  and the Y values will be  $Y_1, Y_2, Y_n$ . Naturally, these data cannot be considered to be independent that means, the value  $Y_1$  will certainly be related to  $X_1$ .

**(Refer Slide Time: 52:21)**

$$\bar{X} - \bar{Y} \pm \sqrt{\frac{S_x^2}{m} + \frac{S_y^2}{n}} t_{p, \frac{n-1}{2}}$$

**Case IV: Paired Observations**

$$\begin{pmatrix} X_1 \\ Y_1 \end{pmatrix}, \begin{pmatrix} X_2 \\ Y_2 \end{pmatrix}, \dots, \begin{pmatrix} X_n \\ Y_n \end{pmatrix} \sim \text{BVN} \left( \begin{pmatrix} \mu_1 \\ \mu_2 \end{pmatrix}, \begin{pmatrix} \sigma_1^2 & \rho\sigma_1\sigma_2 \\ \rho\sigma_1\sigma_2 & \sigma_2^2 \end{pmatrix} \right)$$

Blood sugar level before the treatment X  
 " " " " after the treatment Y

$\mu_1 - \mu_2 = \delta$

Patient	1	2	3	...	n
X :	$x_1$	$x_2$	.	.	$x_n$
Y :	$y_1$	$y_2$	.	.	$y_n$

Because depending upon the structure of the patient, the effect on him will be different than the effect on patient number 2 or the effect on the patient number 3 and so on, so this is the case of paired observations. Now, in this case the methodology that we described till now will not be applicable because in all of them; all those developments I have assumed the independence. Our aim is still the same to set up a confidence interval, say for  $\mu_1 - \mu_2$ .

**(Refer Slide Time: 52:37)**

$$V_i = X_i - Y_i \sim N \left( \delta, \underbrace{\sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2}_{\tau^2} \right)$$

We can consider now interval estimation based on  $V_1, \dots, V_n$   
 $\sim N(\delta, \tau^2)$

So the confidence interval for  $\delta$  will be

$$\left( \bar{V} - \frac{S_V}{\sqrt{n}} t_{n-1, \frac{\alpha}{2}}, \bar{V} + \frac{S_V}{\sqrt{n}} t_{n-1, \frac{\alpha}{2}} \right), \quad S_V^2 = \frac{1}{(n-1)} \sum (V_i - \bar{V})^2$$

$$\bar{V} = \frac{1}{n} \sum V_i$$

But then I can use again the linearity property of bivariate normal distribution. If I consider say,  $V_i$  as say,  $X_i - Y_i$ , then that will follow normal distribution with mean  $X_i$  that is  $\mu_1 - \mu_2$  and variance term as  $\sigma_1^2 + \sigma_2^2 + 2\rho\sigma_1\sigma_2$ . Now, what we can do; we can consider, so this can be written as some  $\tau^2$  again, we can consider now interval estimation based on  $V_1, V_2, V_n$ .

Because now this is reducing to the case of 1 sample problem that means, we can consider  $V_1, V_2, V_n$ , this is following normal  $X_i \tau^2$ , so the confidence interval for  $X_i$  will be  $\bar{V} \pm$ ; well we have considered the say; I will define  $SV^2$  as  $\frac{1}{n-1} \sum V_i - \bar{V}^2$ . So, if we consider this and we make use of the formula, which we develop for the 1 sample problem, let me just take the formula from the previous sheet here.

It was given by  $\bar{X} - S/\sqrt{n} t_{n-1, \alpha/2}$  to the same thing +; if we use this, I will get  $\bar{SV}/\sqrt{n} t_{n-1, \alpha/2}$  to  $\bar{V} + SV/\sqrt{n} t_{n-1, \alpha/2}$ , so this will be the confidence limits, so basically when we have the paired observations, then to obtain the confidence limits for the mean difference, we consider the difference of the observations and we calculate  $\bar{V}$  that is  $\frac{1}{n} \sum V_i$ .

And  $SV^2$  that is a sample variance based on the differences and construct the confidence interval treating this problem as the 1 sample problem itself and we are able to get the confidence limits for this problem also. We also have the problem of ratio of the variances, so what about the confidence interval for that? Again, we can make use of this  $S_1^2$  and  $S_2^2$ , let me just demonstrate that here.

**(Refer Slide Time: 55:44)**

Confidence Interval for  $\eta = \frac{\sigma_2^2}{\sigma_1^2}$

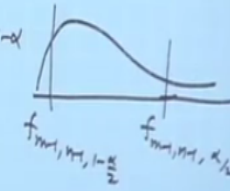

$\frac{(m-1)S_1^2}{\sigma_1^2} \sim \chi_{m-1}^2, \quad \frac{(n-1)S_2^2}{\sigma_2^2} \sim \chi_{n-1}^2$

indep't

$\frac{\frac{(m-1)S_1^2}{\sigma_1^2}}{\frac{(n-1)S_2^2}{\sigma_2^2}} = \frac{\sigma_2^2}{\sigma_1^2} \frac{S_1^2}{S_2^2} \sim F_{m-1, n-1}$

$P\left(f_{m-1, n-1, 1-\alpha/2} \leq \eta \frac{S_1^2}{S_2^2} \leq f_{m-1, n-1, \alpha/2}\right) = 1-\alpha$

So  $\left(\frac{S_2^2}{S_1^2} f_{m-1, n-1, 1-\alpha/2}, \frac{S_2^2}{S_1^2} f_{m-1, n-1, \alpha/2}\right)$

Confidence intervals for say; let me give some name to it say; eta that is = sigma 2 square/ sigma 1 square or 1/eta that is sigma 1 square or 1/eta that is sigma 1 square/ sigma 2 square that is the same thing, so we can consider here m -1 S1 square/ sigma 1 square that is following chi square distribution on m -1 degrees of freedom and m-1 S2 square/ sigma 2 square that is following chi square distribution on n -1 degrees of freedom.

And these 2 are independent, if they are independent, I can construct the ratio here, so I will get m -1 S1 square/ sigma 1 square \* m-1 divided by n -1 S2 square/ sigma 2 square n -1 and this cancels out, so you get sigma 2 square/ sigma 1 square S1 square/ S2 square, this follows F distribution on m -1, n-1 degrees of freedom. So, we can use this to get; F distribution is also a positively skewed distribution.

**(Refer Slide Time: 58:01)**

indep't

$$\frac{\frac{(n-1) S_1^2}{\sigma_1^2 (n-1)}}{\frac{(n-1) S_2^2}{\sigma_2^2 (n-1)}} = \frac{\sigma_2^2}{\sigma_1^2} \frac{S_1^2}{S_2^2} \sim F_{m-1, n-1}$$

$$P \left( f_{m-1, n-1, 1-\alpha/2} \leq \eta \frac{S_1^2}{S_2^2} \leq f_{m-1, n-1, \alpha/2} \right) = 1-\alpha$$

$$\left( \frac{S_2^2}{S_1^2} f_{m-1, n-1, 1-\alpha/2}, \frac{S_2^2}{S_1^2} f_{m-1, n-1, \alpha/2} \right)$$

are confidence limits for  $\eta$ .

So, we consider a  $f_{m-1, n-1, 1-\alpha/2}$  and  $F_{m-1, n-1, 1-\alpha/2}$ , so  $f_{m-1, n-1, 1-\alpha/2} \leq \eta \frac{S_1^2}{S_2^2} \leq f_{m-1, n-1, \alpha/2}$  that is  $= 1 - \alpha$ , so we get the confidence limits here as  $\frac{S_2^2}{S_1^2} f_{m-1, n-1, 1-\alpha/2}$  to  $\frac{S_2^2}{S_1^2} f_{m-1, n-1, \alpha/2}$ , so these are the confidence limits for  $\eta$ ; confidence limits for  $\eta$ . These are under popular application because we are assuming the normal model and I have already mention because of the central limit theorem, are normal distribution solution plays a central role in the theory of the statistics.

Therefore, these methods we can very popular and they are commonly used however, another popular one is when we have the qualitative data, so you have the responses and we may use the binomial model. In the next lecture, I will introduce the confidence intervals for proportions, the difference of proportions etc. and then we will move over to the problem of testing of hypotheses, so that I will be covering in the next lectures.
