Lecture - 19
Multivariate Analysis – IV

So we have considered the density of the Multivariate Normal Distribution in the previous class. Now if we are doing random sampling from Multivariate Normal Distribution then we want to do the estimation of parameters or we want to do the test on the parameters, so in general inferences on the parameters of a multivariate normal distribution. Firstly, I will discuss the part here.

(Refer Slide Time: 00:49)

So let us consider say Random Sample from a Multivariate normal population. So we can consider say U_1, U_2, \dots, U_n let me use this notation so these are independent and identically distributed and $N_p(\mu, \Sigma)$ random variables, so that means these are the observations from a multivariate normal distribution. So we have basically expectation of each U_i that = μ and the dispersion matrix of $U_i = \Sigma$ for $i=1$ to n .

So clearly we can see that if I define $\bar{U} = \frac{1}{n} \sum_{i=1}^n U_i$, then expectation of \bar{U} that will be = μ . So an unbiased estimator for μ is the sample mean, sample mean vector. Similarly, we consider, say $S = \frac{1}{n-1} \sum_{i=1}^n (U_i - \bar{U})(U_i - \bar{U})^T$. This is unbiased for Σ . Let me give the interpretation of this year.

(Refer Slide Time: 03:04)

$$\begin{matrix}
 & \underline{U}_1 & \underline{U}_2 & \dots & \underline{U}_n \\
 \begin{matrix} Y_1' \\ Y_2' \\ \vdots \\ Y_p' \end{matrix} & \begin{bmatrix} U_{11} & U_{12} & \dots & U_{1n} \\ U_{21} & U_{22} & \dots & U_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ U_{p1} & U_{p2} & \dots & U_{pn} \end{bmatrix} & = & U^T \\
 & & & & p \times n
 \end{matrix}$$

Y_i' represents a random sample on the i^{th} component is $N(\mu_i, \sigma_i^2)$

$$\underline{U}_i - \bar{U} = \begin{pmatrix} U_{i1} - \bar{U}_1 \\ \vdots \\ U_{ip} - \bar{U}_p \end{pmatrix}, \quad \bar{U}_i = \frac{1}{n} \sum_{j=1}^n U_{ij}$$

Let us consider the sample in this fashion, U_1, U_2, U_n , I will write it in this fashion. The components of this is U_{11}, U_{21} and so on U_{p1} . Similarly, the components of U_2 are U_{12}, U_{22}, U_{p2} , and components of U_n are U_{1n}, U_{2n} and so on U_{pn} . Let us consider say – I consider this row vector which say Y_1 prime, Y_2 prime, Y_n prime.

And this entire matrix we can use the notation say U transpose which is of order p/n . So we can consider say for example Y_i prime represents a random sample on the i th component that is $n \mu_i \sigma_i^2$. Now let us also use the notation $U_i - \bar{U}$ that is equal to $U_{i1} - \bar{U}_1$ and so on, $U_{pi} - \bar{U}_p$. Here individual U_i bars are denoting $1/n \sum_{j=1}^n U_{ij}$ $j=1$ to n . Therefore, this term, that is $1/n-1 \sum U_i - \bar{U} * 2 U_i - \bar{U}$ transpose that will represent.

(Refer Slide Time: 05:12)

CET
I.I.T. KGP

3

$$\text{Then } \frac{1}{n-1} \sum (U_i - \bar{U})(U_i - \bar{U})^T$$

$$= \frac{1}{n-1} \begin{bmatrix} \sum (U_{1i} - \bar{U}_1)^2 & \sum (U_{1i} - \bar{U}_1)(U_{2i} - \bar{U}_2) & \dots & \dots \\ & \sum (U_{2i} - \bar{U}_2)^2 & & \\ & & \ddots & \\ & & & \sum (U_{pi} - \bar{U}_p)^2 \end{bmatrix}$$

Now $\frac{1}{n-1} \sum (U_{1i} - \bar{U}_1)^2$ is unbiased for σ_1^2

$\frac{1}{n-1} \sum (U_{1i} - \bar{U}_1)(U_{2i} - \bar{U}_2)$ is unbiased for σ_{12} etc.

So $\frac{S}{n-1}$ is unbiased for Σ

So we can write it here $\frac{1}{n-1} \sum (U_i - \bar{U})(U_i - \bar{U})^T$ this will represent $\frac{1}{n-1} S$, the first component will be $\frac{1}{n-1} \sum (U_{1i} - \bar{U}_1)^2$, from here we can write here because if I am considering this multiplied by the transpose of this then the first term will become $\frac{1}{n-1} \sum (U_{1i} - \bar{U}_1)^2$ similarly, in the second diagonal it will become $\frac{1}{n-1} \sum (U_{2i} - \bar{U}_2)^2$ and in the half diagonal it will become $\frac{1}{n-1} \sum (U_{1i} - \bar{U}_1)(U_{2i} - \bar{U}_2)$ etcetera.

Here it will be $\frac{1}{n-1} \sum (U_{2i} - \bar{U}_2)^2$ and so on; $\frac{1}{n-1} \sum (U_{pi} - \bar{U}_p)^2$ is square. Now you can see that $\frac{1}{n-1} \sum (U_{1i} - \bar{U}_1)^2$, this is unbiased for σ_1^2 and so on. $\frac{1}{n-1} \sum (U_{1i} - \bar{U}_1)(U_{2i} - \bar{U}_2)$, this is unbiased for σ_{12} etcetera. So $\frac{S}{n-1}$ is unbiased for Σ . So we are able to consider the unbiased estimation for μ and σ . We had the concept of minimum variance unbiased estimation in the case of a scalar parameter.

Since we are dealing with the vector parameter here, that concept is no longer valid here of course we can consider component wise minimum variance unbiased estimation here. Now in the case of one variable we have seen the like for example in normal μ, σ^2 we have also looked at the maximum likelihood estimators.

In the one dimensional case the maximum likelihood estimator for μ was the sample mean and for the σ^2 it was $\frac{1}{n} \sum (x_i - \bar{x})^2$. So here we can consider analog to that and we will get, here we have to find S , so for the variance covariance matrix σ we will get $\frac{S}{n}$ and for μ we will get \bar{U} . Let us prove this here.

(Refer Slide Time: 08:18)

Maximum Likelihood Estimation of Parameters of a Multivariate Normal Distⁿ.

U_1, \dots, U_n i.i.d from $N_p(\mu, \Sigma)$.

The likelihood fn. is

$$L(\mu, \Sigma, U_1, \dots, U_n) = \frac{|\Sigma|^{-n/2}}{(2\pi)^{np/2}} e^{-\frac{1}{2} \sum_{i=1}^n (U_i - \mu)' \Sigma^{-1} (U_i - \mu)}$$

Consider $\sum_{i=1}^n (U_i - \mu)' \Sigma^{-1} (U_i - \mu)$

$$\sum_{i=1}^n (U_i - \bar{U} + \bar{U} - \mu)' \Sigma^{-1} (U_i - \bar{U} + \bar{U} - \mu)$$

$$\sum_{i=1}^n (U_i - \bar{U})' \Sigma^{-1} (U_i - \bar{U}) + n(\bar{U} - \mu)' \Sigma^{-1} (\bar{U} - \mu)$$

$$+ 2 \sum_{i=1}^n (U_i - \bar{U})' \Sigma^{-1} (\bar{U} - \mu)$$

So Maximum Likelihood Estimation of Parameters of a Multivariate Normal Distribution. So as before we have U_1, U_2, \dots, U_n is a random sample from normal $N_p(\mu, \Sigma)$. Now let us go back to the density function of U_i . **“Professor to Student conversation starts”** Yesterday we have seen the density function of Multivariate Normal Distribution when the rank of sigma is full it is given by $1/2$ to the power $n/2$ determinant of sigma to the power half, e to the power $-1/2$ $(x - \mu)' \Sigma^{-1} (x - \mu)$. Now we write this density for U_1, U_2, \dots, U_n . **“Professor to Student conversation ends”**

So the likelihood function that is we write $L(\mu, \Sigma)$ and then of course your U_1, U_2, \dots, U_n . I continue using capital letters here just for convenience so it will become determinant sigma to the power $-n/2$, $(2\pi)^{np/2}$, e to the power $-1/2$ $\sum_{i=1}^n (U_i - \mu)' \Sigma^{-1} (U_i - \mu)$. So firstly let us simplify this expression, $\sum_{i=1}^n (U_i - \mu)' \Sigma^{-1} (U_i - \mu)$.

Here we add and subtract sample mean vector so this becomes $\sum_{i=1}^n (U_i - \bar{U} + \bar{U} - \mu)' \Sigma^{-1} (U_i - \bar{U} + \bar{U} - \mu)$ and we expand this so $\sum_{i=1}^n (U_i - \bar{U})' \Sigma^{-1} (U_i - \bar{U}) + n(\bar{U} - \mu)' \Sigma^{-1} (\bar{U} - \mu) + 2 \sum_{i=1}^n (U_i - \bar{U})' \Sigma^{-1} (\bar{U} - \mu)$. Now if I consider here summation and apply on this I get $\sum_{i=1}^n (U_i - \bar{U})' \Sigma^{-1} (\bar{U} - \mu) = 0$, so this term is actually 0; this term vanishes. So we are getting only this part here.

(Refer Slide time: 11:54)

So we can rewrite the likelihood fn as

$$L(\mu, \Sigma) = \frac{|\Sigma|^{-n/2}}{(2\pi)^{np/2}} e^{-\frac{1}{2} \sum_{i=1}^n (U_i - \bar{U})' \Sigma^{-1} (U_i - \bar{U}) - \frac{n}{2} (\bar{U} - \mu)' \Sigma^{-1} (\bar{U} - \mu)}$$

$$= \frac{|\Sigma|^{-n/2}}{(2\pi)^{np/2}} e^{-\frac{1}{2} \sum_{i=1}^n \text{tr} \left[\Sigma^{-1} (U_i - \bar{U}) (U_i - \bar{U})' \right] - \frac{n}{2} (\bar{U} - \mu)' \Sigma^{-1} (\bar{U} - \mu)}$$

$$= \frac{|\Sigma|^{-n/2}}{(2\pi)^{np/2}} e^{-\frac{1}{2} \text{tr} \left[\Sigma^{-1} S \right] - \frac{n}{2} (\bar{U} - \mu)' \Sigma^{-1} (\bar{U} - \mu)}$$

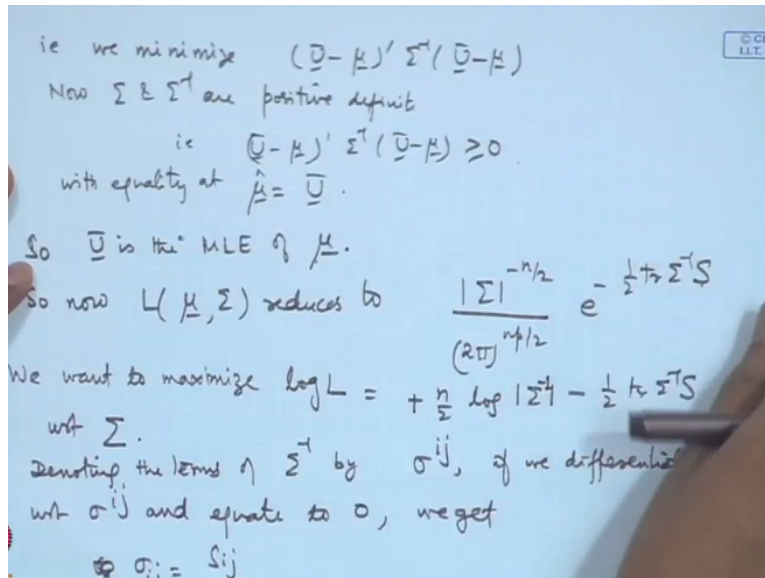

So we can rewrite the likelihood function as $L(\mu, \Sigma)$ that = determinant of sigma to the power $-n/2$ 2π to the power $np/2$, e to the power $-1/2$. Now if you look at this term, this is actually scalar, so if it is a scalar term I can also write it as trace of this, now trace of this can also be written as trace of this I interchange the order here, I multiply it on the side. So let me write it here = sigma U_i - sorry.

This is sigma $U_i - \bar{U}$ prime sigma inverse $U_i - \bar{U}$ half n $\bar{U} - \mu$ prime sigma inverse $\bar{U} - \mu$. Okay. Now this term I write as e to the power half trace of sigma $U_i - \bar{U}$ prime, sigma inverse $U_i - \bar{U}$. Now in the trace, so this will become summation here. I can take the summation outside. So this will become determinant of sigma to the power $n/2$ divided by 2π to the power $np/2$, e to the power $-1/2$ trace of Sigma inverse $U_i - \bar{U}$, $U_i - \bar{U}$ transpose $n/2$ $\bar{U} - \mu$ sigma inverse $\bar{U} - \mu$.

Now I take this summation sign inside then this will become summation here that is becoming S here, so this is determinant of sigma to the power $n/2$, 2π to the power $np/2$, e to the power $-1/2$ trace of sigma inverse S , e to the power $-n/2$ $\bar{U} - \mu$ prime sigma inverse $\bar{U} - \mu$. Now we want to maximize this with respect to μ . Let us consider firstly the maximization with respect to μ , we first maximum with respect to μ .

Now there is no μ term appearing here so that means basically we have to minimize this term.

(Refer Slide Time: 15:19)

So i.e. we minimize $\bar{U} - \mu$, $\mu' \sigma^{-1} \bar{U} - \mu$. Now σ and σ^{-1} are positive definite. So $\bar{U} - \mu' \sigma^{-1} \bar{U} - \mu$ is always $>$ or $= 0$ with equality at μ had is equal to \bar{U} . So \bar{U} is the maximum likelihood estimator of μ . So if I have reduced the second term in the likelihood function to 0 so my likelihood function is now reducing to this term alone.

So now let us consider the maximization of this with respect to σ . So now, $L(\mu, \sigma)$ reduces to determinant of σ to the power $-n/2$, π to the power $n/2$, e to the power $-$ half trace of $\sigma^{-1} S$. And we want to maximize. So let us consider maximization of $\log L$ that $= -n/2 \log$ of determinant of σ - half trace of $\sigma^{-1} S$. So this we want to maximize with respect to σ .

So if I—here, actually you can see I can put $+$ here then this will become $-$. So if considering terms of σ^{-1} and we can denote, denoting the terms of σ^{-1} by say σ_{ij} , if we differentiate $\log L$ with respect to σ_{ij} and equate to 0 we get $\sigma_{ij} = S_{ij}/n$. Now in order to prove that this is maximum likelihood estimator we should show that actually this is maximizing, that means we must show that--

(Refer Slide Time: 18:24)

To prove that $\frac{S}{n}$ actually maximizes $\ln L$, we must show that

$$n \ln |\Sigma^{-1}| - \frac{1}{2} \text{tr} \Sigma^{-1} S \geq n \ln \left| \frac{S}{n} \right| - \frac{1}{2} \text{tr} \left(\frac{S}{n} \right)$$

$$= n \ln |\Sigma^{-1}| - \text{tr} \Sigma^{-1} S - \left[n \ln \left| \frac{S}{n} \right| + n p \right] \leq 0$$

$$= n \left[\ln \left| \frac{\Sigma^{-1} S}{n} \right| - \text{tr} \left(\frac{\Sigma^{-1} S}{n} \right) + p \right]$$

$$= n \left[\ln \left| \frac{\Sigma^{-1/2} S \Sigma^{-1/2}}{n} \right| - \text{tr} \left(\frac{\Sigma^{-1/2} S \Sigma^{-1/2}}{n} \right) + p \right]$$

$$= n \left[\ln \prod_{i=1}^p \lambda_i - \sum_{i=1}^p \lambda_i + p \right]$$

Now $\ln x - x + 1 \leq 0 \quad \forall x > 0$
 So $\frac{S}{n}$ is MLE of Σ .

$|\Sigma^{-1} S| = |\Sigma^{-1/2} \Sigma^{-1/2} S| = |\Sigma^{-1/2} S \Sigma^{-1/2}|$
 $\lambda_1, \dots, \lambda_p$ are ch. roots of $\frac{\Sigma^{-1/2} S \Sigma^{-1/2}}{n}$.
 $\lambda_i > 0$

To prove that S/n actually maximizes log of L , we must consider we must show that $n \log$ determinant σ inverse $- \frac{1}{2} \text{tr} \sigma$ inverse S is always $>$ or $= n \log S/n$ inverse $- \frac{1}{2} \text{tr}$ of S inverse $n S$. Or we can say that this difference should be $>$ or $= 0$. Now this difference if you consider this is $n \log$ determinant of σ inverse S/n minus trace of half I can remove here because in this terms $2/2$ was and here also divided by 2 was here, so I can take it out so this I can remove and this term also I can remove.

So this will become trace of σ inverse $S - n \log$, so now it is S/n inverse and here S inverse S will become i , so i of P dimension so trace will become $= P$, so the term will become P here - and there is a n in the denominator so it will become nP and this will become $+$ here. Now this term we can write as n times \log of σ inverse S/n determinant, I am combining this term with this minus trace of σ inverse S/n , I am taking out n here $+P$.

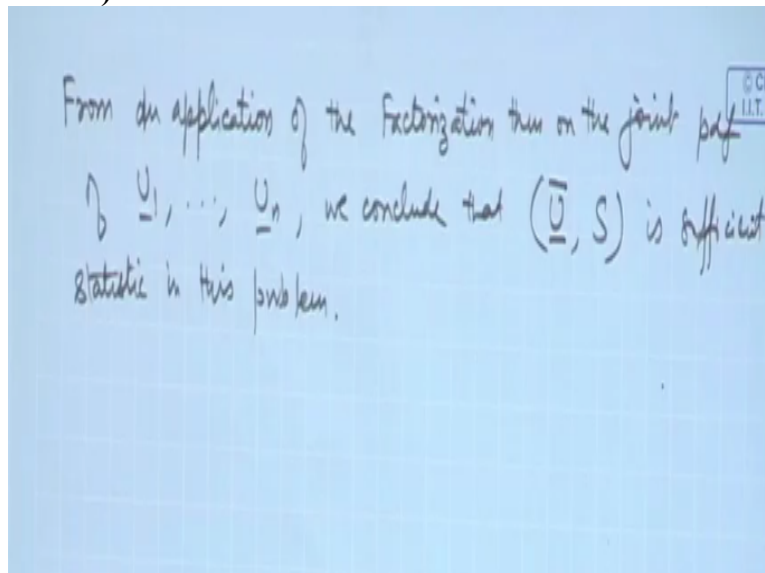

That we can write as n time \log of, now here we do some manipulation. This σ is actually σ inverse S so we can write it as σ to the power $- \frac{1}{2}$; σ to the power $- \frac{1}{2} S$. Now determinant of $AB =$ determinant of BA . Now these type of breakup was allowed provided we assume σ to be a positive definite matrix that is why σ inverse is existing, it is a positive definite matrix we were having a decomposition and from that decomposition the inverse was also possible and then the half matrix was also allowed.

If you remember the calculations that we did in it in one of the previous lectures so we will use that thing here. So this I can write as log of determinant of sigma to the power $-\frac{1}{2}$ minus $\frac{1}{2}$ trace of sigma to the power $\frac{1}{n}$. Now in the trace also same argument can be used because trace of AB is also = trace of BA. Now this is equal to n times log of product of λ_i $i=1$ to $n-p$.

Here $\lambda_1, \lambda_2, \dots, \lambda_p$ they are characteristic roots of sigma to the power $-\frac{1}{2}$ minus $\frac{1}{2}$ trace of sigma to the power $\frac{1}{n}$. And since this is we are starting with the positive definite these are all positive. Now if we consider log of $x-x+1$ this is always ≤ 0 if I take $x=0$. So if you look at this term this is always going to be ≤ 0 . So actually we wanted to prove that S/n maximizes.

So in the log L I substituted $\sigma=S/n$ that is why I got $n \log S/n$ inverse-trace of sigma inverse that was becoming S/n inverse S. So I should show this is ≤ 0 not > 0 . So this is what we are able to prove. So S/n is maximum likelihood estimator of sigma. Also if you look at the likelihood function which is actually the joint density function form, that we have written here. So from here we can also conclude that \bar{U} and S it is sufficient statistics for this problem.

(Refer Slide Time: 24:00)

From an application of the Factorization theorem on the joint pdf of U_1, U_2 we conclude that \bar{U} and S is sufficient. So this fact will be further useful in the inference problems. So let us summarize, we have considered the Multivariate Normal Distribution and we have discussed

several properties of the multivariate normal distribution. Now one or two important points that we saw was use of a non-central chi-square distribution because we have seen that some of the squares of independent normal random variable is a central chi-square.

So if we are considering normal distribution with some non-zero mean, and then if I consider some of the squares then we will get a non-central chi-square. So I will now introduce non-central distribution, they are extremely useful in the multivariate theory. So let me start with the non-central chi-square and then gradually we will talk about non-central T and non-central F distributions also.

(Refer Slide Time: 26:00)

Non-Central Chi-Square Distⁿ

Let $X \sim N(\mu, 1)$, $Y = X^2$. We derive the distⁿ of Y .

Consider the cdf of Y :

$$F_Y(y) = P(Y \leq y) = 0, \quad \forall y < 0$$

$$= P(|X| \leq \sqrt{y}), \quad \forall y > 0$$

$$= P(-\sqrt{y} \leq X \leq \sqrt{y}) = P(-\sqrt{y}-\mu \leq Z \leq \sqrt{y}-\mu), \quad Z \sim N(0, 1)$$

$$= \Phi(\sqrt{y}-\mu) - \Phi(-\sqrt{y}-\mu).$$

Now the probability density fn. of Y as

$$f_Y(y) = \begin{cases} \frac{1}{2\sqrt{y}} \phi(\sqrt{y}-\mu) + \frac{1}{2\sqrt{y}} \phi(-\sqrt{y}-\mu), & y > 0 \\ 0, & y < 0 \end{cases}$$

$\phi(t)$ denotes the pdf of $N(0, 1)$ distⁿ
 $\phi(t) = \frac{1}{\sqrt{2\pi}} e^{-t^2/2}, \quad -\infty < t < \infty$
 $\Phi(x) = \int_{-\infty}^x \phi(t) dt$
 \downarrow
cdf of $N(0, 1)$ distⁿ.

So we talk about Non-Central Chi-square distribution. So let us consider say x following normal $\mu, 1$ distribution. We have seen that if x follows normal $0, 1$ then $y = x^2$ as a chi-square 1 distribution. Now if x is normal $\mu, 1$ then $x - \mu$ square will be chi-square 1 , but what about x square itself, so let us derive the distribution here. To derive the distribution, we consider, we derive the distribution of y .

So let us consider the cdf of y , so naturally this is going to be 0 if y is < 0 . So this = modulus $x < \text{or} = \text{root } y$ if y is 0 . So let us consider this portion here. So this = probability of $-\text{root } y < \text{or} = x < \text{or} = \text{root } y$. Now that = we transform it to standard normal then this is becoming Z is $< \text{or} = \text{root } y - \mu$ and here - here z follows normal $0, 1$. So this in terms of capital phi function which is a cdf of standard normal distribution, we can write it as.

So we have derived the cumulative distribution function of x square, so we can also find out the probability density function, so derivative of capital phi will be small phi. So let us revise the definition. This is small phi t denotes the pdf of standard normal distribution that is $\phi(t) = \frac{1}{\sqrt{2\pi}} e^{-t^2/2}$ and capital phi x that is nothing but the cumulative distribution function that is cdf of normal 0, 1 distribution.

So if I differential capital phi I will get a small phi the root y-Mu and I will get $1/2 \sqrt{y}$. And here I will get, there is a - here and there will be - here, so it will become $+1/2 \sqrt{y}$ small phi - y-Mu. This is for $y > 0$, it is 0 for y. So of course equality at 0 we may include at one of the points that does not make any difference here.

(Refer Slide Time: 30:00)

$$\begin{aligned}
 &= \frac{1}{\sqrt{2\pi}} \frac{1}{2\sqrt{y}} \left[e^{-\frac{1}{2}(\sqrt{y}-\mu)^2} + e^{-\frac{1}{2}(-\sqrt{y}-\mu)^2} \right] \\
 &= \frac{1}{2\sqrt{2\pi y}} \left[e^{-\frac{y}{2} - \frac{\mu^2}{2} + \mu\sqrt{y}} + e^{-\frac{y}{2} - \frac{\mu^2}{2} - \mu\sqrt{y}} \right] \\
 &= \frac{e^{-\frac{y}{2} - \frac{\mu^2}{2}}}{2\sqrt{2\pi y}} \left[e^{\mu\sqrt{y}} + e^{-\mu\sqrt{y}} \right] \\
 &= \frac{e^{-\frac{y}{2} - \frac{\mu^2}{2}}}{\sqrt{2\pi y}} \sum_{k=0}^{\infty} \frac{(\mu\sqrt{y})^{2k}}{(2k)!}
 \end{aligned}$$

Now this we simplify. We can write it as $1/2 \sqrt{y}$ and $1/\sqrt{2\pi}$ will also come out and I will get e to the power half root y-Mu square+1, e to the power $+1/2 - \text{root } y - \text{Mu square}$. I am writing the part where the density is positive, in the 0 part I am not writing here. Let us simplify this portion. So this is becoming $= 1/2 \sqrt{2\pi y}$ and this term here I can write e to the power $-y/2 - \text{Mu square}/2 + \text{Mu root } y$.

Similarly, in the second part it will become $-y/2 - \text{Mu square}/2$ and this one will give me the - sign, $-\text{Mu root } y$. So this term I can keep outside, it will be become e to the power $-y/2 - \text{Mu square}/2$ root $2\pi y$, I get e to the power $\text{Mu root } y + e$ to the power $-\text{Mu root } y$. If we consider the

expansion of e to the power $\mu \sqrt{y}$ and e to the power $-\mu \sqrt{y}$, so this becomes simply e to the power $-\frac{y}{2} - \frac{\mu^2}{2}$ divided by.

Here in terms will be $+$ and $-$ so they will get canceled out and the even terms will get added up. And if you then you will get two times so this 2 will go away, I will get divided by $\sqrt{2}$ $\mu \sqrt{y}$ to the power $2k/2k$ factorial $k=0$ to infinite. Now let us substitute here, say $\mu^2/2 = \text{say } \lambda$, then this will become e to the power $-\lambda - y/2$ / $\sqrt{2\pi y}$ λ to the power $k/2k$ factorial.

I multiply and divide by k factorial here. So let us simplify this here.

(Refer Slide Time: 33:05)

$$= \sum_{k=0}^{\infty} \frac{e^{-\lambda} \lambda^k}{k!} \cdot \frac{1}{2^{\frac{2k+1}{2}} \Gamma(\frac{2k+1}{2})} e^{-\frac{y}{2}} \cdot y^{\frac{2k+1}{2} - 1}$$

$$= \sum_{k=0}^{\infty} \frac{e^{-\lambda} \lambda^k}{k!} f_{1+2k}(y) \quad \text{where } f_m(y) \text{ denotes the pdf of } \chi_m^2 \text{ dist}^n$$

So this is the pdf of a non-central chi-square on 1 degree of freedom and the non-centrality parameter $\lambda (= \mu^2/2)$.
This is a weighted pdf.

$X \sim N_p(\mu, I), \mu \neq 0$
 $Y = X^T X = \sum_{i=1}^p X_i^2$ has non-central Chi-square with p d.f. & non-centrality parameter λ .

This will become = -- I combine the terms in the particular way, e to the power $-\lambda$, λ to the power k/k factorial; $1/2$ to the power $2k+1/2$ $\Gamma(2k+1/2)$; e to the power $-y/2$; y to the power $2k+1/2-1$. So I have combined all the terms in a very particular way, let us see how it is coming. So e to the power $-\lambda$, λ to the power k/k factorial I am writing here. Then there is another term that is $2k$ factorial and then there will be a k factorial here.

So here I can actually cancel the terms like here I will get $2k$, so I will cancel with the first term here then I will get $2k-2$ that I cancel with $k-1$ and so on. Now what is remaining is $2k-1$; $2k-2$ and so on-- no $2k-3$ and so on, so that terms I combined and it can be written as a $\Gamma(2k+1/2)$ because there is a divided by 2 terms coming here. Now the terms which I left here, that is for

example 2^k so there was a 2 here, then there was another 2^{k-1} and so on, that will be again coming here, and then there is a square root 2 here, so that I put together as 2 to the power $k + 1/2$.

Then there is a e to the power $-y/2$ term that I write here and the power of y to the power $2k/2$ and then here we have $-1/2$ so that I write as half -1 . So this particular way of writing down this gives it as interpretation that it is $= \int_0^\infty e^{-\lambda y/2} (\lambda y/2)^{k/2} / \Gamma(k/2) y^{k/2-1} dy$ where this $f_m(y)$ denotes the density of chi-square m distribution. So the interpretation for the density function of a y which is $= x^2$.

Here $y=x^2$ and the interpretation for the density of that is, it is a weighted, because these are Poisson's weights of central chi-square. So this is the pdf of non-central chi-square on one degree of freedom and the non-centrality parameter λ , λ is actually $\mu^2/2$. This is a weighted pdf; the weights are actually the Poisson weights here. So now, let us consider x to be $N(\mu, \sigma^2)$.

That means I am considering p components so x_1, x_2, \dots, x_p are independent normal which means $\mu_1, \mu_2, \dots, \mu_p$ and variances are unity and they are independent and in general I am assuming μ to be non-zero because at 0 it will simply give me chi-square central chi-square. So now I am looking at $y=x^2$ that is $\sum_{i=1}^p x_i^2$. So then this has non-central chi-square with p degrees of freedom and non-centrality parameter.

λ that is half μ^2 , that is $\sum_{i=1}^p \mu_i^2/2$ λ that is $1/2 \sum_{i=1}^p \mu_i^2$ that is $\sum_{i=1}^p \mu_i^2/2$. Let us look at this.

(Refer Slide Time: 38:14)

Let Γ be an orthogonal matrix with first row as $\frac{\mu'}{\|\mu\|}$ & other rows are orthogonal to it.

$$\Gamma = \begin{pmatrix} \frac{\mu'}{\|\mu\|} \\ \vdots \\ \vdots \end{pmatrix} \perp \text{ to first row.}$$

Let $\underline{z} = \Gamma' \underline{x} \quad \underline{z} \sim N_p(\Gamma' \mu, I)$

$$\Gamma' \mu = \begin{pmatrix} \|\mu\| \\ 0 \\ \vdots \\ 0 \end{pmatrix} \quad \underline{x}' \underline{x} = \underline{z}' \Gamma \Gamma' \underline{z} = \underline{z}' \underline{z} = \sum z_i^2$$

Exp $\underline{z} = \begin{pmatrix} z_1 \\ \vdots \\ z_p \end{pmatrix} \quad z_1^2 \sim \chi^2(1, \lambda)$

Let us define gamma to be an orthogonal matrix with first row as say new prime/ norm of Mu. And other rows are orthogonal to it. That is, I am writing gamma = something like Mu prime by norm of Mu and other rows these are orthogonal okay, orthogonal to first row. Let us consider say z=gamma x then z will follow Np gamma Mu, i. But what is gamma Mu? Gamma Mu= because this Mu, so Mu prime Mu you will get.

So that is norm of Mu square so you will get norm of Mu and other terms will become 0 because the other rows are orthogonal to the first row. So if I consider x prime x that=z prime gamma, gamma prime z that=z prime Z because gamma is orthogonal that = simply sigma Zi square. So if I consider the first component that is Z=Z1, Z2, Zp then Z1 square will follow chi-square 1 lambda.

That is non-central chi-square distribution with one degree of freedom and lambda as the non-centrality parameter. So this we will write as chi-square p lambda and this one we are writing as chi-square one lambda, sometimes we write as chi-square one lambda like this also, that is chi-square p lambda. So these are various forms of this notation here. So Z1 square is chi-square 1 lambda and what you are getting is Z prime Z that = to Z1 square+Z2+Zk square.

So these are central chi-square, so what you are getting chi-square 1+2k where k is Poisson lambda + chi-square 1+chi-square 1, these are central and these are all independent.

(Refer Slide Time: 41:20)

So we conclude that $Z \sim \chi^2_{p+2K}$

i.e. density of $Y = Z^2$ is $\sum_{k=0}^{\infty} \frac{e^{-\lambda} \lambda^k}{k!} f_{p+2k}(y)$

$$E(Y) = E(E(Y|K)) = E(p+2K) = p+2E(K) = p+2\lambda$$

$$= p + \|\mu\|^2.$$

The ch. fn. of Y

$$\phi_Y(t) = E(e^{itY}) = E(E(e^{itY}|K)) = E\left[(1-2it)^{-\frac{p+2K}{2}}\right]$$

$$= (1-2it)^{-p/2} \cdot E(1-2it)^{-K}$$

$$= (1-2it)^{-p/2} \sum_{k=0}^{\infty} (1-2it)^{-k} \cdot \frac{e^{-\lambda} \lambda^k}{k!}$$

So we conclude that Z follows chi-square $p+2k$ that is pdf of say V or say $W=Z$ that will be $= e^{-\lambda} \lambda^k / k!$ where $k=0$ to infinite. We can look at some elementary properties for example, we have written actually $y=x$, now $x=z$ so this is actually y the density of y .

So if we consider expectation of y we can write it as expectation of y/K , that is equal to expectation of $p+2k$ because for a chi-square distribution if k is given then it becomes central and it is equal to the number of degrees of freedom, that is $p+2$ expectation of k that is $p+2\lambda$, that is $p + \|\mu\|^2$. We can also consider the characteristic function of y that is $E(e^{itY})$ that is expectation of e^{itY} .

So that is equal to expectation of e^{itY} given k . So that is -- given k it is chi-square so we know it is equal to expectation of $(1-2it)^{-p+2k/2}$. Now to consider the expectation of this with respect to k we consider the k following Poisson λ here, so it is $(1-2it)^{-p/2}$ expectation of $(1-2it)^{-k}$, that is $(1-2it)^{-p/2}$, because k is following Poisson λ .

Now this term can be combined with this so you get it as simply $(1-2it)^{-p/2}$ $\sum_{k=0}^{\infty} \frac{e^{-\lambda} \lambda^k}{k!} (1-2it)^{-k}$.

(Refer Slide Time: 44:49)

$$= (1-2it)^{-p/2} e^{-\lambda} e^{\frac{\lambda}{1-2it}}$$

$$= (1-2it)^{-p/2} e^{\frac{2it\lambda}{1-2it}}$$

Non-central F : let $W_1 \sim \chi_p^2(\lambda)$, $W_2 \sim \chi_q^2$
and W_1, W_2 be indep.

Then $\frac{W_1/p}{W_2/q}$ is said to have a non-central F distⁿ
with p, q d.f. & non-centrality
parameter λ .

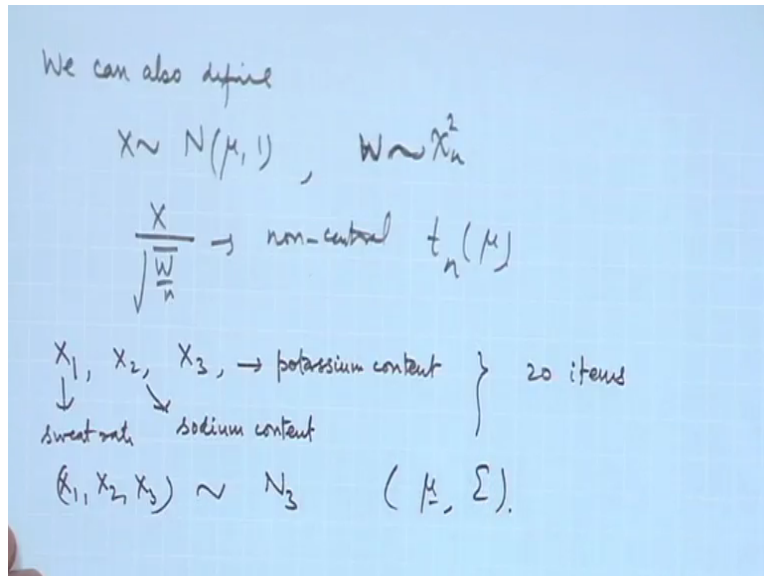

Doubly Non-central F \leftarrow $W_1 \sim \chi_p^2(\lambda)$, $W_2 \sim \chi_q^2(\tau)$
 $\frac{W_1/p}{W_2/q} \rightsquigarrow$ doubly

So you can get that $(1-2it)^{-p/2} e^{-\lambda} e^{\frac{\lambda}{1-2it}}$ to the power $\lambda/(1-2it)$ to the power λ . So after combining the terms, now once we are aware to determine the characteristic function of the non-central chi-square distribution other characteristics like and other things can also be found out easily. So I am leaving this discussion at this point. Now, if you remember the definition of T-distribution the definition of F-distribution we have made use of the chi-square.

So now if that chi-square is replaced by a non-central chi-square the similar changes will occur. So let me define, non-central F, so let say W_1 follow chi-square p λ and W_2 follow chi square say q . And W_1 and W_2 be independent then W_1/p divided by W_2/n is said to have a non-central F with say—sorry this is q here with p and q degrees of freedom and non-centrality parameter λ .

Now there can be possibility that the denominator chi-square is also non-central so we call it Doubly non-central F, say W_1 follows chi-square p λ and W_2 follows chi-square Q τ . So in that case if we consider $W_1/p/W_2/q$, then this is called Doubly Non-Central F. Of course they should be independent.

(Refer Slide Time: 47:53)

We can also define X following normal $\mu, 1$ and say W follow chi-square n . Then if I consider $x/\text{root } W/n$ and this is called non-central t . So these are some of the distribution that are used in when we deal with general multivariate normal distribution and these quantities will be appearing in the distributions of the tested statistics which we use for constructing the test for the parameters of a multivariate normal distribution or for constructing the confidence intervals etcetera.

Now in the case of Univariate normal distribution we had that x_1, x_2, \dots, x_n , if they are it is a random sample and if we consider the sample variance $\sum (x_i - \bar{x})^2 / (n-1)$ and we called it as S^2 . We have obtained distribution of that that is $\sum (x_i - \bar{x})^2 / \sigma^2$ it follows chi-square distribution $n-1$ that is the freedom. Now what could be a possible generalization of this to multi-dimension.

Because in the multi-dimension for variance covariance matrix Σ we are getting the sample variance covariance matrix S , so we are considering $S/(n-1)$ by as estimator, so what could be the distribution of that. So we need the concept of a matrix distribution. So in the next lecture I would be covering this matrix distribution for this. Let us look at one or two applications of the sampling from multivariate distribution.

Suppose I am considering say x_1, x_2, x_3 so these are considered as sweat rate; x_2 is considered as the sodium content; x_3 is considered as the potassium content. So this is data on 20 times. So

it is assumed that x_1, x_2, x_3 this is having N_3 distribution with say μ and σ and data is calculated data is observed in the following fashion.

(Refer Slide Time: 50:59)

$x_1, x_2, x_3 \rightarrow$ potassium content } 20 items
 \downarrow sweat rate }
 \downarrow sodium content }

$(x_1, x_2, x_3) \sim N_3(\mu, \Sigma)$

item	1	2	...	20
x_1	3.7	5.7	...	5.5
x_2	48.5	65.1	...	40.9
x_3	9.3	8.0	...	9.4

If we want MLEs of μ, Σ
 Here we can take sample mean vector
 $\frac{1}{20} \sum_{i=1}^{20} x_{1i}, \frac{1}{20} \sum_{i=1}^{20} x_{2i}, \frac{1}{20} \sum_{i=1}^{20} x_{3i}$
 μ

MLE of Σ
 $\frac{1}{20} \sum_{i=1}^{20} (x_{1i} - \bar{x}_1)^2, \frac{1}{20} \sum_{i=1}^{20} (x_{2i} - \bar{x}_2)^2, \frac{1}{20} \sum_{i=1}^{20} (x_{3i} - \bar{x}_3)^2$
 $\frac{1}{20} \sum_{i=1}^{20} (x_{1i} - \bar{x}_1)(x_{2i} - \bar{x}_2), \frac{1}{20} \sum_{i=1}^{20} (x_{1i} - \bar{x}_1)(x_{3i} - \bar{x}_3), \frac{1}{20} \sum_{i=1}^{20} (x_{2i} - \bar{x}_2)(x_{3i} - \bar{x}_3)$

For item number 1, so for each item we are writing down the values of x_1, x_2, x_3 . So it is 3.7, 48.5, 9.3. For the second item it is 5.7, 65.1, 8.0 like that up to 20. We are having for 20th item 5.5, 40.9, 9.4. So if we want say maximum likelihood estimators of μ and σ then here we can consider mean vector sample mean vector we can consider here σ say $x_{1i} \ i=1$ to $n \ 1/n$, so $1/20$ here $1/20 \sum x_{2i} \ 1/20; \sigma \ x_{3i}$ etcetera.

So this will give the MLE of μ . For calculation of the MLE or σ then I need to consider $1/19 \sum_{i=1}^{20} (x_{1i} - \bar{x}_1)^2 \ 1/20; \sigma \ x_{2i} - \bar{x}_2$ square $1/20; \sigma \ x_{3i} - \bar{x}_3$ square. We also need to calculate the cross product terms like $1/20 \sum_{i=1}^{20} (x_{1i} - \bar{x}_1)(x_{2i} - \bar{x}_2) \ 1/20 \sum_{i=1}^{20} (x_{1i} - \bar{x}_1)(x_{3i} - \bar{x}_3) \ 1/20 \sum_{i=1}^{20} (x_{2i} - \bar{x}_2)(x_{3i} - \bar{x}_3)$.

I.I.T. KGP

$$\frac{1}{20} \sum x_i^2 - \bar{x}_1^2, \quad \frac{1}{20} \sum x_i x_j - \bar{x}_1 \bar{x}_j$$

$$\underline{X} \sim N_5(\underline{\mu}, \Sigma), \quad \underline{\mu} = \begin{pmatrix} 2 \\ 4 \\ -1 \\ 3 \\ 0 \end{pmatrix}, \quad \Sigma = \begin{pmatrix} 4 & -1 & 1/2 & -1/2 & 0 \\ -1 & 3 & 1 & -1 & 0 \\ 1/2 & 1 & 6 & 1 & -1 \\ 1/2 & -1 & 1 & 4 & 0 \\ 0 & 0 & -1 & 0 & 2 \end{pmatrix}$$

$$\underline{X} = \begin{pmatrix} X^{(1)} \\ \underline{X} \\ X^{(4)} \end{pmatrix}, \quad X^{(1)} = \begin{pmatrix} X_1 \\ X_2 \end{pmatrix}, \quad X^{(4)} = \begin{pmatrix} X_3 \\ X_4 \\ X_5 \end{pmatrix}$$

Find conditional distⁿ of $\underline{X}^{(1)}$ given $\underline{X}^{(4)} = \begin{pmatrix} 0 \\ 2 \\ -1 \end{pmatrix}$.

Σ $\underline{X}^{(4)}$ given $\underline{X}^{(1)} = \begin{pmatrix} 1 \\ 5 \end{pmatrix}$. Let $A = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$, $B = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & -2 \end{pmatrix}$

Find detⁿ of $A \underline{X}^{(1)}$, $B \underline{X}^{(4)}$, $\text{Cov}(A \underline{X}^{(1)}, B \underline{X}^{(4)})$.

For calculation purpose the simplifications can be done, for example one may use like $1/20 \sum x_i^2 - \bar{x}_1^2$ say $x_i^2 - 20 \bar{x}_1^2$ so this will get canceled out. And similarly, for the cross product term you may consider $1/20 \sum x_i x_j - \bar{x}_1 \bar{x}_j$ etcetera, so one may consider these quantities also for simplification. I end up with some exercise. Let us consider say \underline{x} following $N_5(\underline{\mu}, \Sigma)$ and I define $\underline{\mu}$ as the $2, 4, -1, 3, 0$ and Σ matrix as $4, -1, 1/2, -1, 3, 1, -1, 0; 1/2, 1, 6, 1, -1; 0, -1, 1, 4, 0; 0, 0, -1, 0, 2$. So this is a $5/5$ matrix.

Let us consider say $\underline{x} = x_1$ and x_2 , where x_1 I am taking to be x_1, x_2 and x_2 I am taking to be x_3, x_4, x_5 . So find conditional distributions of say x_1 given $x_2 = 0, 2, -1$. And x_2 given say $x_1 = 1, 5$. Let us also take $A =$ say $1, 1, 1, 1$ and $B =$ say $1, 1, 1; 1, 1, -2$. Find the distributions of $A \underline{x}_1, B \underline{x}_2$, covariance between $A \underline{x}_1, B \underline{x}_2$. Also find P that is $2/2$ matrix and Q $3/2$ such that $P \underline{x}_1$ and $Q \underline{x}_2$ are independently distributed. So I am leaving it as an exercise, you can try.

“Professor to Student conversation starts”. So in the next lecture I will consider a matrix distribution for the sample dispersion matrix S . So it is called Wishart distribution in the next lecture I will introduce this thing.” **Professor to Student conversation ends.”**
