**Multivariate Analysis – V**

Now, I will discuss the variance, covariance matrix  $S$  the sample variance covariance matrix. So for that if we derive the distribution it will be a matrix distribution, it is called Wishart Distribution.

**(Refer Slide Time: 00:34)**

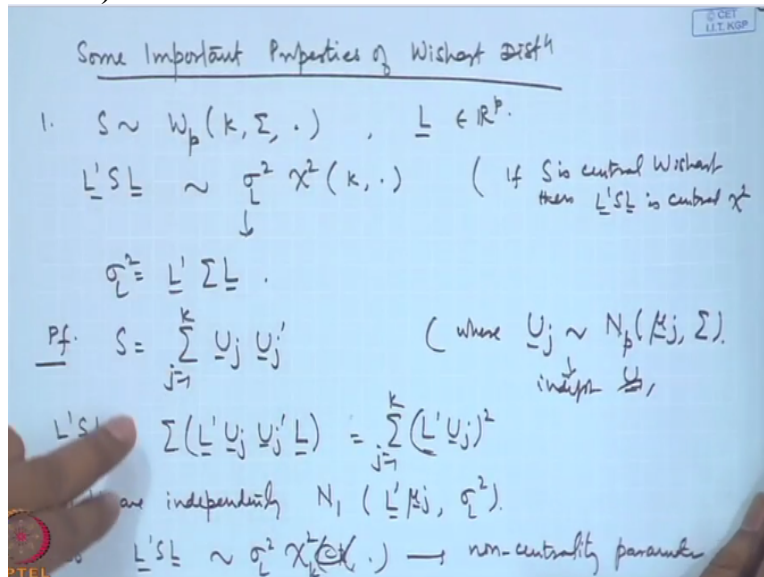

So we can consider this Wishart distribution as a generalization of the chi-square distribution in the Univariate case the sample variance had a chi-square distribution, in fact we wrote it in the form that sigma x/x square/sigma square that follows a chi-square distribution on m-1 degrees of freedom. So now we consider all the components of the dispersion sample dispersion matrix, so we are having sigma x1i-x1 bar square sigma x1i-x1 bar\*x2i-x2 bar and so on.

So what is the distribution of that? So let us define the Wishart distribution. So let  $U_1, U_2, U_k$  be independent  $N_p(\mu_j, \Sigma)$  where  $j=1$  to  $k$ . Then we say that  $\sum_{j=1}^k U_j U_j^T$ ,  $j=1$  to  $k$ , this is said to follow Wishart distribution with  $k$  degrees of freedom and we write as following  $W_p(k, \Sigma, M)$ . This  $S$  is  $p/p$ , so we let us write this as  $S$  here. And here  $M$  is the non-centrality matrix. This is of order  $k/p$ .

Now, when  $M = \text{null matrix}$  then  $S$  is said to have a central Wishart distribution. And the density function of-- so we write  $W_p(K, \Sigma, \cdot)$ ,  $\Sigma \in \mathbb{R}^{p \times p}$ . For  $p=1$   $W_1(k, \sigma^2, \cdot)$  that is in  $W_1(k, \sigma^2)$  that is  $\chi^2(k, \sigma^2)$ . Similarly, non-central Wishart will reduce to non-central  $\chi^2$  for  $p=1$ . Before talking about the density function of a Wishart distribution it is quite complicated actually.

**(Refer Slide Time: 04:18)**

So we firstly look at its properties like the case for multivariate normal distribution. So, some important properties of Wishart distribution. The first properties are that if I have  $S$  following Wishart with parameters  $p, k, \Sigma$  and here I am not writing that  $M$  here because I can consider both the case of central and non-central here. And  $L$  is a fixed vector in the  $p$  dimensional space. Then  $L' S L$  that will have  $\sigma^2 \chi^2(k)$ .

And again if  $S$  is central Wishart then  $L' S L$  is central  $\chi^2$ . And here the  $\sigma^2$  I am defining to be  $L' \Sigma L$ . For proof of this now we will make use of the non-central  $\chi^2$ . So  $S$  is written as  $\sum_{j=1}^k U_j U_j'$  where we are actually considering  $U_j$  as the multivariate normal. So if I consider and these are independent, okay  $U_1, U_2$  but because that was a setup that we consider here,  $U_1, U_2, U_k$  are independently distributed.

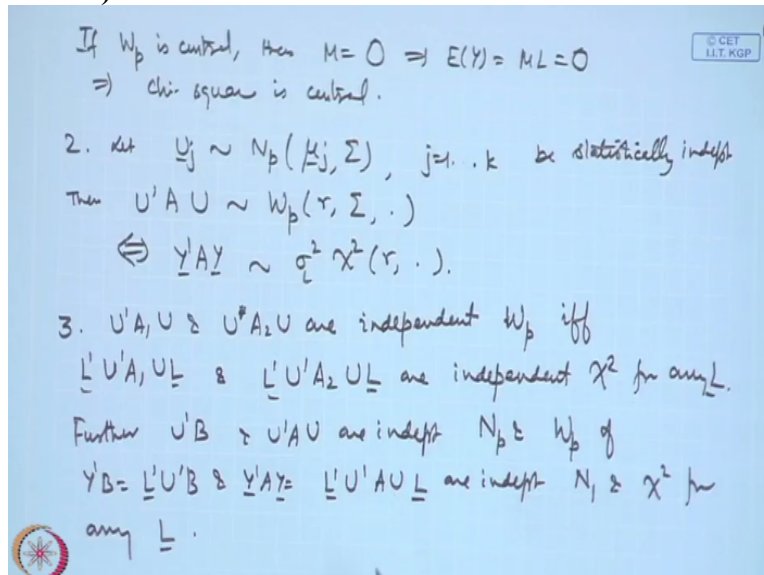

So let us write here  $L' S L = \sum_{j=1}^k L' U_j U_j' L = \sum_{j=1}^k (L' U_j)^2$ . So  $L' U_j$  these are independent, these are independently distributed normal  $N_1(L' \mu_j, \sigma^2)$ . So  $L' S L$ , this will follow  $\sigma^2 \chi^2(k)$ .

on k degree of freedom and this non-centrality parameter will come there as we discussed in the previous lecture.

That if I am considering  $x$  following  $N_p(\mu, I)$ , then  $x'$  has a non-central square distribution with  $p$  degrees of freedom and non-centrality parameter is given by summation  $\mu_j^2$ . So if you use this then-- because what we are getting here this  $L'$  prime  $\mu_j$  they are univariate normal so of course we have put  $\sigma^2$   $L$  square if I divide by that then that will come here. So this result follows here.

Now if my original Wishart is central then  $M$  will be 0 so expectation of  $y$  that will be 0, so chi-square will be central. Let us write that also.

**(Refer Slide Time: 08:22)**

If Wishart is central then  $M$  is 0 null matrix, this implies expectation of  $y$  is  $ML$  that is 0, this implies chi-square is central. So we have shown a direct correspondence between a Wishart and Chi-square distribution as we have seen in the case of multivariate normal every linear combination is univariate normal. So here in place of linear combination it is quadratic form, so  $S$  is a positive ( $()$ ) (09:07) matrix and considering  $L$  prime  $SL$  so this is a quadratic form.

But the quadratic form will have a chi-square distribution. Let us look at the second property. So once again we are considering  $U_j$  following  $N_p(\mu_j, \Sigma)$  where  $j=1$  to  $k$ , suppose they are independent then if I consider. Now in the previous one I defined what is  $U$ , I defined the matrix

here as  $U$ , so if I use this  $U$  as components of  $U_1, U_2, \dots, U_n$  then if I consider  $U$  prime  $A$   $U$  then this will have Wishart.

This is equivalent to saying  $Y$  prime  $AY$ ; this will be  $\sigma^2 L$  square chi-square  $r$ . I will skip the proof of this because it involving lot of terms and I do not want to make this course extremely theoretically work. Let us move to further properties of the--  $U$  prime  $A_1$ ,  $U$  and  $U$  prime  $A_2$ ,  $U$  they are independent, independent Wishart iff  $L$  prime  $U$  prime  $A_1$ ,  $UL$  and  $L$  prime  $U$  prime  $A_2$ ,  $UL$  they are independent chi-square for any  $L$ .

Further  $U$  prime  $B$  and  $U$  prime  $AU$  are independent  $N_p$  and Wishart  $P$  if  $Y$  prime  $B$  that =  $L$  prime  $U$  prime  $B$  and  $Y$  prime  $A$   $Y$  that =  $L$  prime  $U$  prime  $A$   $U$   $L$  they are independent  $N_1$  and chi-square for any  $L$ . This relation is actually similar to the relation that in the sampling form univariate normal distribution the sample mean and the sample variance are independently distributed. So this is of similar nature.

So now let us talk about the Joint Distribution of the Sample mean and the Sample Covariance matrix.

**(Refer Slide Time: 12:21)**

Joint Dist<sup>n</sup> of the Sample Mean & Sample Covariance Matrix

Let  $U_1, \dots, U_n$  be a random sample from  $N_p(\underline{\mu}, \underline{\Sigma})$  dist<sup>n</sup>

$L'U_1, \dots, L'U_n$  is a random sample  $L \in \mathbb{R}^p$

from then  $N_1(L'\underline{\mu}, L'\underline{\Sigma}L)$ .

$$\frac{1}{n} \sum_{i=1}^n L'U_i = L'\bar{U}$$

$$\sum_{i=1}^n \{L'(U_i - \bar{U})\}^L = L' \sum_{i=1}^n (U_i - \bar{U})(U_i - \bar{U})' L = L'SL$$

are independently distributed. Further

$$L'\bar{U} \sim N_1\left(L'\underline{\mu}, \frac{L'\underline{\Sigma}L}{n}\right), \quad L'SL \sim L'\underline{\Sigma}L \chi^2_{(n-1)}$$

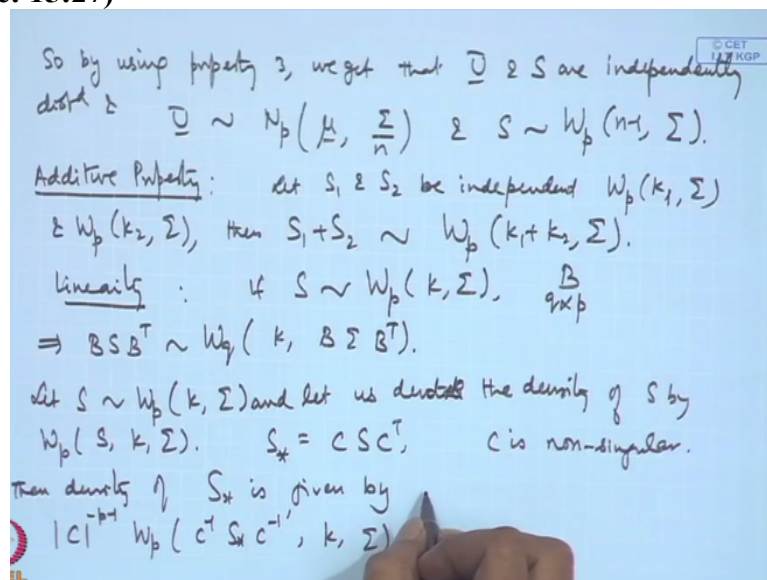

So let  $U_1, U_2, \dots, U_n$  be a random sample from  $N_p$   $\mu$ ,  $\sigma$  distribution. Then if I consider  $L$  prime  $U_1$  and so on  $L$  prime  $U_n$  for any  $L$ ,  $L$  is a  $p$  dimensional vector then this is a random sample from  $N_1$   $L$  prime  $\mu$ ,  $L$  prime  $\sigma$   $L$ . So if I consider the sample mean  $1/n$   $\sigma$   $L$

prime  $U_i$ . And if I consider the sample covariance matrix  $L \text{ prime } U_i - \bar{U} \text{ square } i=1 \text{ to } n \text{ that } = L \text{ prime } \Sigma U_i - \bar{U} U_i - \bar{U} \text{ prime } L \text{ that } = L \text{ prime } S L$ .

So from the distribution theory of a univariate normal distribution the sample mean and the sample variance covariance matrix are sample variance, sample covariance is independently distributed. They are independently distributed further  $L \text{ prime } U$  that will be univariate normal  $L \text{ prime } \mu$ ,  $L \text{ prime } \Sigma L$  by  $n$  and  $L \text{ prime } S L$  will have  $L \text{ prime } \Sigma L$  chi-square on  $n-1$ .

So now if we use this result this is iff and non-if here so we will get that  $\bar{U}$  will have multivariate normal and  $S$  will have Wishart.

**(Refer Slide Time: 15:27)**

So by using property 3, we get that  $\bar{U}$  and  $S$  are independently distributed and  $\bar{U}$  will follow  $N_p \mu$ ,  $\Sigma/n$  and  $S$  will follow Wishart  $n-1$   $\Sigma$ . So this is a central Wishart distribution. Now like the additive property of chi-square distribution Wishart also has additive property. Let  $S_1$  and  $S_2$  be independent so Wishart  $k_1$ ,  $\Sigma$  and  $k_2$ ,  $\Sigma$ , then  $S_1+S_2$  will follow Wishart  $k_1+k_2$ ,  $\Sigma$ .

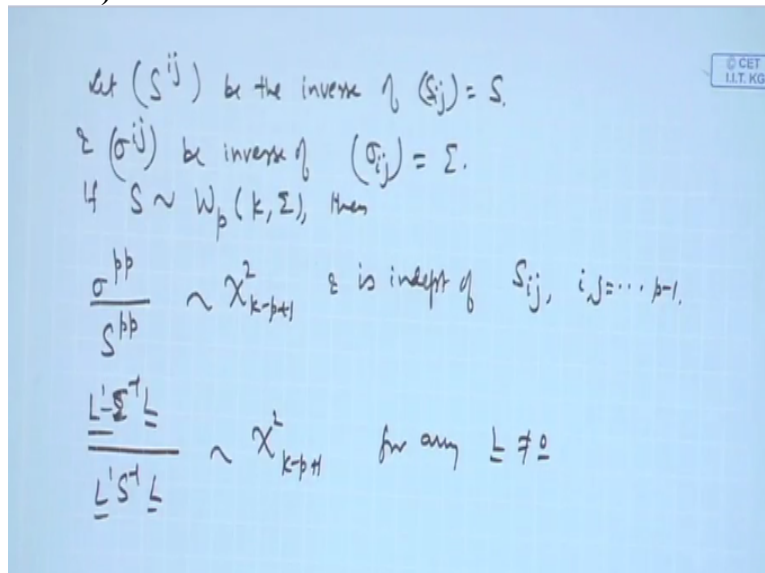

Once again we can prove this result by considering  $L \text{ prime } S_1 L$  and  $L \text{ prime } S_2 L$ , so there will be central chi-square and then there will be additive so it will become  $k_1+k_2$ . In the case of multivariate normal distribution, we have considered linear combination that means if I consider

x as a  $N_p$  and if I considering B as a  $q/p$  matrix then  $Bx$  will have  $N_q$  distribution. Now a similar thing is proved Wishart also.

So this is linearity we can say. If S follow  $W_p, k, \sigma$  and the B is the  $q/p$  matrix then  $BSB^T$  will follow Wishart  $q$  with  $B \sigma B^T$ . So the result will follow from definition of the Wishart distribution. Let us talk about the density part here. Let us follow Wishart  $k, \sigma$  and let us denote the density of S/ say  $W_p(S, k, \sigma)$ . Let us define  $S^*$  that =  $CSC^T$  where C is non-singular.

Then density of  $S^*$  is given by, so by a transformation of this we get determinant of C to the power  $-p-1$   $W_p(C^{-1}S^*C^{-T}, k, \sigma)$ .

**(Refer Slide Time: 19:20)**

Let us  $S_{ij}$  be the inverse of  $S_{ij}$  that is equal to  $S$  and  $\sigma_{ij}$  be inverse of  $\sigma_{ij}$  that is equal to  $\sigma$ . Now, if S is having the Wishart distribution then we have  $\sigma_{pp}/S_{pp}$  that is following chi-square  $k-p+1$  and this is independent of  $S_{ij}$   $i, j=1$  to  $p-1$ . At the same time  $L^{-1} \sigma^{-1} L / L^{-1} S^{-1} L$  that follow chi-square  $k-p+1$  for any  $L$  not 0.

In the case of multivariate normal we have seen the conditional distribution, a similar thing is true for the Wishart also. Now, we have these properties I am stating without proofs because the proofs are quite involved using multivariate parts here.

**(Refer Slide Time: 20:56)**

$$\frac{\sigma^{pp}}{S^{pp}} \sim \chi_{k-p+1}^2 \quad \varepsilon \text{ is indept of } S_{ij}, i, j = \dots, p-1.$$

$$\frac{\underline{L}' \underline{\Sigma}^{-1} \underline{L}}{\underline{L}' \underline{S}^{-1} \underline{L}} \sim \chi_{k-p+1}^2 \quad \text{for any } \underline{L} \neq 0$$

Conditional dist<sup>n</sup> of components

$$S \sim W_p(k, \Sigma), \quad S = \begin{pmatrix} S_{11} & | & S_{12} \\ \dots & & \dots \\ S_{21} & | & S_{22} \end{pmatrix} \begin{matrix} r \\ s \end{matrix}$$

So you should know the results here. So Conditional distribution of components. So suppose I assume Wishart distribution with parameter  $k$  and  $\Sigma$  and  $S$  is partition  $S_{11}$ ,  $S_{12}$ ,  $S_{21}$  and  $S_{22}$ . Suppose these are  $r$  components and these are  $s$  components here. Similarly, here this is  $r$  components this is  $s$  components here.

**(Refer Slide Time: 21:39)**

Then  $S_{22} - S_{21} S_{11}^{-1} S_{12} \sim W_s(k-r, \Sigma_{22} - \Sigma_{21} \Sigma_{11}^{-1} \Sigma_{12})$

If  $S \sim W_p(k, \Sigma)$ ,  $|\Sigma| \neq 0 \Rightarrow \frac{|S|}{|\Sigma|}$  is dist<sup>d</sup> as a product of  $p$  indept central  $\chi^2$  variables with dof  $k-p+1, \dots, k-1, k$ .

If  $S_i \sim W_p(k_i, \Sigma)$ ,  $i=1, 2$ ,  $S_1$  &  $S_2$  are indept. If  $k_i \geq p$  then  $\Lambda = \frac{|S_1|}{|S_1 + S_2|}$  is dist<sup>d</sup> as product  $p$ -indept beta variables with parameter  $(\frac{k_1-p+1}{2}, \frac{k_2}{2}), (\frac{k_1-p+2}{2}, \frac{k_2}{2}), \dots, (\frac{k_1}{2}, \frac{k_2}{2})$ .

In case  $k_2=1$ , the product of beta variables will be same as a beta with  $(\frac{k_1-p+1}{2}, \frac{p}{2})$ .  $\Lambda(p, k_1, k_2)$

Then  $S_{22} - S_{21} S_{11}^{-1} S_{12}$  that has a Wishart on  $S$   $k-r$ ,  $\Sigma_{22} - \Sigma_{21} \Sigma_{11}^{-1} \Sigma_{12}$ . One more representation of the decomposition of the Wishart determinant is given by the following. If I say  $S$  follows Wishart  $k$ ,  $\Sigma$  determinant of  $\Sigma$  is non-zero then determinant of  $S$ /determinant of  $\Sigma$  is distributed as a product of  $p$  independent central chi-square variables with degrees of freedom  $k-p+1$  and so on  $k-1, k$ .

And if  $S_i$  follow Wishart  $k_i$ ,  $\Sigma$   $i=1,2$ .  $S_1$  and  $S_2$  are independent, if  $k_1$  is  $>$  or  $= p$  then  $\lambda$  that = determinant of  $S_1/S_1+S_2$  is distributed as product of  $p$  independent beta variables  $k_1-p+1/2, k_2/2, k_1-p+2/2, k_2/2$  and so on,  $k_1/2, k_2/2$ . In case,  $k_2=1$ , the product of beta variables is will be same as a beta with  $k_1-p+1/2, p/2$ . So this distribution is denoted the  $\lambda$   $p, k_1, k_2$ .

So these distributions are use in the study of the covariance coefficient etcetera which I am not paying too much attention at this point here. Now we move to another distribution which is extremely useful. So here we have introduced a Wishart distribution as a generalization of a chi-square distribution and we looked at some of the properties.

So in the testing for the variance, covariance matrix of a multivariate normal distribution you can make use of this and the test are other information will be based Wishart distribution. Let us also consider the concept of t-distribution for the univariate distribution. In the concept of t-distribution came when we are considering the inference on mean but variance is unknown, so we are divided by estimate of sigma that is  $S$  there and that was said to have a t-distribution.

Now a similar concept to exist are the when we are considering inference on the mean vector or the multivariate normal distribution. And when the variance covariance matrix is not known. So as a generalization of t-distribution we are considering Hotelling's T square distribution.

**(Refer Slide Time: 26:02)**

Hotelling's  $T^2$  dist<sup>n</sup>

Let  $S \sim W_p(k, \Sigma)$  &  $d \sim N_p(\delta, c^T \Sigma)$ .

Suppose  $S$  &  $d$  are indept.

Hotelling's generalized  $T^2$ - statistic is defined as

$$T^2 = c k \frac{d' S^{-1} d}{d' \Sigma^{-1} d} = k \frac{d' S^{-1} d}{d' \Sigma^{-1} d} \cdot c d' \Sigma^{-1} d$$

$\frac{d' \Sigma^{-1} d}{d' S^{-1} d} \rightarrow \chi^2_{k-p+1}$  for a given  $d$ .

$\therefore$  it is indept of  $d$ .

So let us consider say  $S$  following  $W_p(k, \Sigma)$  and say  $d$  follows  $N_p(\delta, \Sigma^{-1})$ . Suppose  $S$  and  $d$  are independent, in that case this Hotelling's generalized  $T$  square statistics is defined as  $T^2 = c k d' S^{-1} d$ . Now this we can interpret as  $k d' S^{-1} d$  divided by  $d' \Sigma^{-1} d$  into  $d' \Sigma^{-1} d$ . And this  $c$  also we write here. Now if you look at this term here, this is having chi-square  $k-p+1$  for a given  $d$ .

So this property we did at the earlier, this was  $L' \Sigma^{-1} L / L' S^{-1} L$ . So we have written this property but this will have a chi-square distribution, rather arrears of this, not this  $d' \Sigma^{-1} d / d' S^{-1} d$ , this is having a chi-square distribution on  $k-p+1$  degrees of freedom. And it is independent of  $d$ .

**(Refer Slide Time: 28:14)**

$$T^2 = c k d' S^{-1} d = k \left( \frac{d' S^{-1} d}{d' \Sigma^{-1} d} \right) c d' \Sigma^{-1} d$$

$$\frac{d' \Sigma^{-1} d}{d' S^{-1} d} \rightarrow \chi^2_{k-p+1} \text{ for a given } d$$

$\therefore$  it is independent of  $d$ . So this can be considered as unconditional dist<sup>n</sup> of  $d' \Sigma^{-1} d / d' S^{-1} d$ .

So this can also be considered as unconditional distribution of  $d' \Sigma^{-1} d / d' S^{-1} d$ .

**(Refer Slide Time: 28:43)**

© CET  
I.I.T. KGP

Now  $d \sim N_p(\underline{\delta}, c^{-1}\Sigma)$

$c d' \Sigma^{-1} d \sim \chi^2(p, c\tau^2) \quad \tau^2 = \delta' \Sigma^{-1} \delta$

Hence  $\frac{T^2}{k} \equiv \frac{\chi^2(p, c\tau^2)}{\chi^2_{k-p+1}} \rightarrow \text{indep}$

$\Rightarrow \frac{k-p+1}{p} \cdot \frac{T^2}{k} \sim F(p, k-p+1, c\tau^2) \rightarrow \text{noncentral F-dist.}$

If  $\underline{\delta} = \underline{0}$ , then we have a central F-dist.

Now,  $d$  is following multivariate normal. So if I consider the  $c, d$  prime sigma inverse  $d$  that will have chi-square with  $p$  and  $c$  Tau square where Tau square =  $\delta' \Sigma^{-1} \delta$ . Hence your  $T^2/k$  is actually chi-square  $p, c$  Tau square / chi-square  $k-p+1$ . So these are ratio, so this is something like a non-central F distribution which I used in the previous class, that if I consider ratio of--

If I have a central chi-square and in the denominator I have an in the denominator I have central chi-square and in the numerator I have a non-central chi-square, then the ratio is a non-central F. So actually we are able to get come to that situation now that this is and these 2 are independent. Basically we are writing here  $k-p+1/p$   $T^2/k$  follows F distribution so that is non-central F. If  $\delta = 0$  then we have a central F. Let us consider an alternative representation.

**(Refer Slide Time: 31:00)**

Let us consider an alternative representation.

$$T^2 = c k d' S^{-1} d$$

$$\Rightarrow \left(1 + \frac{T^2}{k}\right)^{-1} = \frac{1}{1 + c d' S^{-1} d} = \frac{|S|}{|S + c d d'|}$$

(Pf) 
$$\begin{vmatrix} S_{p \times p} & -c d \\ d' & 1 \end{vmatrix} = |S + c d d'|$$

$$\begin{vmatrix} S_{p \times p} & -c d \\ d' & 1 \end{vmatrix} = |S| |1 + c d' S^{-1} d|$$

Now  $c d d' \sim W_p(L, \Sigma)$  (when  $\delta = 0$ ).

So Hotelling's  $T^2$  (after a monotone transformation) is a special case of  $\Lambda = \frac{|S_1|}{|S_1 + S_2|}$  with  $k=1$ .

In the alternative representation let us consider as  $T^2 = c k d' S^{-1} d$ . So we can write  $1 + T^2/k$  inverse =  $1 / (1 + c d' S^{-1} d)$  this = determinant of  $S$  / determinant of  $S + c d d'$ . See to prove this statement we can actually consider  $c S$  which is  $p/p - c d$  which is  $p/1, d'$  prime which is of course  $1/p$  and  $1$ . Let us consider the determinant then this can be determinant of  $S + c d d'$  which I can write as determinant of  $S^{-1} + c d' S^{-1} d$ .

Now  $c d d'$  prime that will have Wishart 1 sigma when  $\delta = \text{null}$ . So Hotelling's  $T^2$  square after monotone transformation is a special case of  $\lambda = S_1 / (S_1 + S_2)$  with  $k=1$ .

**(Refer Slide Time: 33:15)**

So  $\frac{1}{1 + \frac{T^2}{k}}$  has  $B\left(\frac{k-p+1}{2}, \frac{p}{2}\right)$ .

The density of Wishart

Theorem:  $U'$  has density  $p(U) = f(U'U)$

Then density of  $S = U'U$  is  $\propto f(S) |S|^{\frac{k-p-1}{2}}$ .

$$\frac{1}{w(p,k)} |S|^{-k/2} |S|^{\frac{k-p-1}{2}} e^{-\frac{1}{2} \text{tr } \Sigma^{-1} S}$$

Generalized Variance  $|S|$ .

So this we have already proved that this will have  $1 / (1 + T^2/k)$  has beta distribution with parameter  $k-p+1/2$  and  $p/2$ . So we are actually able to divide find out the distribution which is a

generalization of the student t-distribution here. I will not be giving the derivation of the density of the Wishart distribution, we simply give the expression here the density of Wishart, so we have the following result. If we  $U$  prime  $p/k$  has density of the form  $U$  prime  $U$  then density of  $S$  that is equal to  $U$  prime  $U$  is proportional to  $F(s)$  determinant of  $S$  to the power  $k-p-1/2$ .

So I am considering the density of  $S$  as a constant times I will write only the final expression here  $1/w(p,k)$  which is some constant determinant to the  $\sigma^{-k/2}$ ; determinant of  $S$  to the power  $k-p-1/2$   $e$  to the power  $-1/2$   $\sigma$  of inverse  $S$ . Many times we consider generalized variance that is determinant of  $S$ . The distribution of the determinant of  $S$  can also be obtained. In terms of this we also define sample correlation coefficient etcetera.

Let me express this terms of Wishart.

**(Refer Slide Time: 35:42)**

Consider 2-dimensional case  
 $S \sim W_p(k, \Sigma)$   
 $r = \frac{S_{12}}{\sqrt{S_{11} S_{22}}} \rightarrow$  sample correlation coefficient  
 is MLE of  $\rho = \frac{\sigma_{12}}{\sqrt{\sigma_{11} \sigma_{22}}}$   
 The density of  $r^2$   
 $\frac{(1-\rho^2)^{k/2}}{\Gamma_{\frac{k}{2}} \Gamma_{\frac{k}{2}}} (1-\rho^2)^{\frac{k}{2}} \sum_{l=0}^{\infty} \frac{e^{-2l} \left(\frac{k}{2}+l\right)^2}{2^l \Gamma_{l+\frac{1}{2}}} (r^2)^{l-\frac{1}{2}}$

Consider 2-dimensional case. In the 2-dimensional case  $S$  will follow Wishart  $2$   $k$   $\sigma$ . Then  $r=S_{12}/\text{square root of } S_{11} s_{22}$ , this is actually the sample correlation coefficient. This is actually maximum likelihood estimator of row that is  $\sigma_{12}/\text{square root } \sigma_{11} \sigma_{22}$ .

So the distribution of  $r$ , or it function can be determine it is given by the density of  $r$  square is given by  $1-\rho^2$  to the power  $k/2/\Gamma_{k/2} \Gamma_{k/2}$   $1/r$  square to the power  $k/3/2$   $\sigma$   $\rho$  to the power  $2l$   $(\gamma/2+1)$  square/ $L$  factorial  $\Gamma_{L+1/2}$ ,  $L=0$  to infinite;  $r$

square to the power  $\rho-1/2$ . And the density of  $r$  can be obtained from here. We also have the asymptotic distribution of  $r$  which can be used for the inference purpose.

**(Refer Slide Time: 37:32)**

$$\frac{\sqrt{k}(r-\rho)}{1-\rho^2} \rightarrow Z \sim N(0,1) \text{ as } k \rightarrow \infty \text{ ( } k=n-1 \rightarrow \infty \text{ )}$$

Fisher's  $Z = \frac{1}{2} \ln \frac{1+r}{1-r}$ ,  $\beta = \frac{1}{2} \ln \frac{1+\rho}{1-\rho}$

$\sqrt{n}(Z-\beta) \rightarrow N(0,1) \text{ as } n \rightarrow \infty$

So for testing  $H_0: \rho = \rho_0$   
 vs  $H_1: \rho \neq \rho_0$ ,

we can use  $|\sqrt{n}(Z-\beta)| > Z_{\alpha/2}$

Sometimes  $\sqrt{n-3}$  is found to be better approximation

Square root  $k r-k/1-\rho$  square, this converges following normal 0,1 as  $k$  times to infinite that is  $n$  times to infinite, here  $k=n-1$ . And we also define Fisher's  $Z$  that is half log  $1+r/1-r$ . And if I consider  $x_i = \frac{1}{2} \ln \frac{1+\rho}{1-\rho}$  then square root  $n Z - x_i$  this also converges to normal 0,1 as  $n$  tends to infinite. So for testing  $H_0: \rho = \rho_0$  vs  $H_1: \rho \neq \rho_0$ , we can use  $\sqrt{n} Z - x_i > Z_{\alpha/2}$ .

Sometimes  $\sqrt{n-3}$  is found to be better approximation. Next, we define multiple correlated coefficients which is used in the multivariate analysis. Like in the case of one variable in the case of 2 variables we have discussed the Karl Pearson coefficient of correlation. Similarly, in the several variables we defined multiple correlation coefficients, so let me define that here.

**(Refer Slide Time: 39:22)**

combinations  $a'Z$  of  $Y$ .

If  $X$  and  $Y$  are one-dimensional, then multiple corr. coeff between  $X$  &  $Y$  will be  $\max(\rho, -\rho) = |\rho_{X,Y}|$ .

Let  $X = \begin{pmatrix} Y \rightarrow 1 \\ Z \rightarrow p-1 \end{pmatrix}$        $D(X) = \begin{pmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{pmatrix}$

$\max_a \rho^2(Y, a'Z)$        $a \in \mathbb{R}^{p-1}$

$= \max_a \frac{(a' \Sigma_{21})^2}{\sigma_{11} (a' \Sigma_{22} a)}$        $= \max_b \frac{(b' \Sigma_{22}^{-1/2} \Sigma_{21})^2}{\sigma_{11} b'b}$        $b = \Sigma_{22}^{1/2} a$

**“Professor to student conversation starts”** I have avoided deriving the distributions of various terms in this multivariate portion, those who are interested can look at the book Introduction to Multivariate Analysis by T. W. Anderson, the chapter on multivariate analysis in the book Linear Statistical Inference and its application by C.R. Rao. And there are some other books also for example, M S Srivastava book on Multivariate analysis they consider this distribution theory. Not considering here to save the time here. **“Professor to student conversation ends”**

So let us consider say, let  $x$  be a random variable and let  $y$  be a random vector. Then the multiple correlation coefficient between  $x$  and  $y$  is defined to be the maximum of correlation coefficient between  $x$  and all linear combinations  $a$  prime of  $Rho$ . If  $x$  and  $y$  are one dimensional then maximum of  $Rho$  and  $-Rho$  multiple correlation coefficient between  $x$  and  $y$  be maximum of  $Rho$  and  $-Rho$  that is equal to modulus of  $Rho$   $x$ ,  $Rho$   $y$ . Now let us consider say  $x=y$  and  $z$ .

So this is one dimensional and this is say  $p-1$  dimensional. So  $x$  is a  $p/1$  vector, and we want to define the multiple correlation coefficient here. And we partition the special matrix as  $\sigma_{11}$ ,  $\sigma_{12}$ ,  $\sigma_{21}$ ,  $\sigma_{22}$ . So this is here 1 dimensional scalar and this is  $p-1$  dimensional. So let us consider say maximum of correlation coefficient let us put this square here between  $y$  and  $a$  prime  $z$ , where  $a$  is a  $p-1$  dimensional vector.

So we want to maximize this with respect to  $a$ . So this =  $a$  prime  $\sigma_{21}$  square /  $\sigma_{11}$   $a$  prime  $\sigma_{22} a$ . We are considering the maximum of this with respect to  $a$ . so this we can write

as we can substitute  $b$  as  $\sigma_{22}^{-1/2} a$ . So if you put that we will get this as maximum with respect to  $b$ ,  $b$  prime  $\sigma_{22}$  to the power  $-1/2$   $\sigma_{21}^2 / \sigma_{11} b$  prime  $b$ .

Now here we can apply (C) (43:50).

**(Refer Slide Time: 43:52)**

The image shows a whiteboard with handwritten mathematical work. At the top, it says "This upper bound is obtained when  $a = \Sigma_{12} \Sigma_{22}^{-1}$ ". Below this, a ratio of quadratic forms is written: 
$$\frac{\rho^2(\gamma, \Sigma_{12} \Sigma_{22}^{-1} z)}{\sigma_{11} \Sigma_{12} \Sigma_{22}^{-1} \Sigma_{22} \Sigma_{22}^{-1} \Sigma_{21}} = \frac{\Sigma_{12} \Sigma_{22}^{-1} \Sigma_{21}}{\sigma_{11}} = \rho_M^2$$
 Finally, the maximum value is given as 
$$\rho_M = \left( \Sigma_{12} \Sigma_{22}^{-1} \Sigma_{21} / \sigma_{11} \right)^{1/2}$$

So this quantity will be  $<$  or  $=$  maximum of  $b$  prime  $b$   $\sigma_{12}$ ,  $\sigma_{22}$  inverse  $\sigma_{21}$  divided by  $\sigma_{11} b$  prime  $b$ . But this term here is canceled out so here is quantity become free from  $b$ . This is upper bound is actually obtained, this is attempt when  $a = \sigma_{12} \sigma_{22}$  inverse.

So we are getting here  $\rho$  square  $\gamma$   $\sigma_{12} \sigma_{22}$  inverse  $Z$  that is  $= \sigma_{12} \sigma_{22}$  inverse  $\sigma_{21}^2$  divided by  $\sigma_{11} \sigma_{22}$  inverse  $\sigma_{23} \sigma_{22} \sigma_{21}$ , so this becomes identity and we will get this term can canceled out so you get simply  $\sigma_{12} \sigma_{22} \sigma_{21} / \sigma_{11}$ . So this we call  $\rho$  m square. So  $\rho$  m is actually  $= \sigma_{12} \sigma_{22}$  inverse  $\sigma_{21} / \sigma_{11}$  to the power half.

**(Refer Slide Time: 45:36)**

A MLE of  $\rho_m^2$  will be  $R^2 = \frac{S_{12} S_{22}^{-1} S_{21}}{S_{11}}$

$\frac{R^2}{1-R^2} = \frac{S_{12} S_{22}^{-1} S_{21}}{S_{11} - S_{12} S_{22}^{-1} S_{21}}$   $S \sim W_p(k, \Sigma)$

$= \frac{Z}{\chi_{k-p+1}^2}$

$Z | X_k \sim \chi_{p-1}^2 \left( \frac{\rho_m^2}{2(1-\rho_m^2)} \chi_k^2 \right)$

If  $\rho_m = 0 \Leftrightarrow \Sigma_{12} = 0$

$\Rightarrow \frac{R^2}{1-R^2} \sim F_{p-1, k-p+1}$

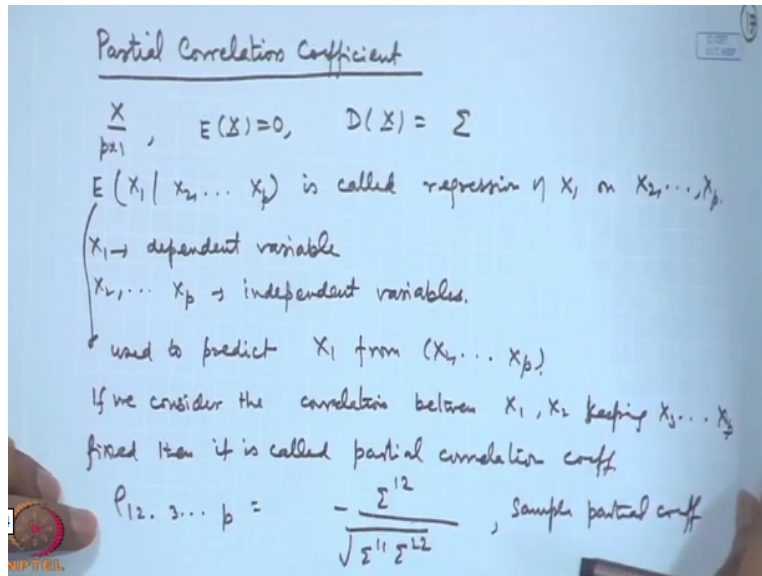

Now a maximum likelihood estimator of Rho m square, this will become simply r square which is calculated simply from the sample analog of this. Later on we will show that in the multiplication analysis, we use this r square as the coefficient of determination and it is an important indicator of the goodness of the regression model that is fitted there.

Now the distribution of r square can also be obtained by distribution theory that I have discussed earlier but I will not be giving the final results here. Actually we can see here that if I consider r square/1-r square then this term is actually =  $S_{12} S_{22}^{-1} S_{21} / (S_{11} - S_{12} S_{22}^{-1} S_{21})$ . So if I am considering S following Wishart k sigma then this will follow this can be written as Z/chi-square k-p+1.

And the general distribution of Z given chi-square k is chi-square p-1 Rho m square by twice 1-Rho m square chi-square k. So if Rho m is 0 then sigma 12 is 0 and this will imply that r square/1-r square has F distribution on p-1 k-p+1 degrees of freedom. So the distribution of the multiple correlation coefficient after a transformation is shown to be F when Rho m = 0. So this is used for the testing of hypothesis regarding multiple correlation coefficients.

**(Refer Slide Time: 47:36)**

Likewise, we can also talk about Partial Correlation Coefficient. Suppose  $x$  is a  $p/1$  vector with expectation  $x=0$  and dispersion matrix =  $\sigma$ . Then expectation of  $x_1$  given  $x_2$  to  $x_p$  this is called regression of  $x_1$  on  $x_2$  to  $x_p$ . So here  $x_1$  is known as dependent variable, we will discuss this in detail in when we do the regression but right now let me just introduce for the purpose of definition here. And  $x_2$  to  $x_p$  these are called independent variables.

So this is use to predict  $x_1$  from  $x_2$  to  $x_p$ . If we consider the correlation between  $x_1$   $x_2$  keeping  $x_3$  to  $x_p$  fixed, then it is called partial correlation coefficient. So we have for example  $\rho_{12.3}$  up to  $p$  that is equal to  $-\sigma_{12}$  divided by square root  $\sigma_{11} \sigma_{22}$ . And one can obtain sample partial correlation coefficient. From here by considering  $-\sigma_{12}/\sqrt{\sigma_{11} \sigma_{22}}$ .

**“Professor to student conversation starts”** I will conclude today’s lecture by giving some exercise here for calculation of this coefficient and also for testing here. **“Professor to student conversation ends”**

**(Refer Slide Time: 50:41)**

①  $\frac{S}{n} = \begin{bmatrix} 95.29 & 52.86 & 69.66 & 46.11 \\ 52.86 & 54.36 & 51.31 & 35.05 \\ 69.66 & 51.31 & 100.81 & 56.54 \\ 46.11 & 35.05 & 56.54 & 45.02 \end{bmatrix}$

Find  $R^2$ . Let  $R^2 = \xi$ .

Test the hyp.  $H_0: R^2 = [\xi]$   
vs  $H_1: R^2 \neq [\xi]$ .

Also find partial correlation coefficients.

②

	1	2	3	4	5	6	7	8	9	10
$x_1$	1.8	0.7	1.0	0.2	0.2	4.2	5.3	1.5	4.7	3.3
$x_2$	0.8	-1.5	-0.3	-1.3	0	3.2	3.9	0.7	0.1	2.2

So  $S/n$  is given by say 95.29 52.85 69.66 46.11 52.86 54.36 51.31 35.05 69.66 51.31 100.81 56.54 46.11 35.05 56.54 45.02. Fine  $R^2$ . Let  $R^2 = \xi$ . Then test the hypothesis that  $H_0: R^2 = \xi$  versus  $H_1: R^2 \neq \xi$ . Also find partial correlation coefficients.

So this is one exercise another exercise I am asking. Let us consider the data on the performance of student on 2 test, so some performance majors are given here 1 1.8 0.8 2 0.7 -1.5 3 1.0 -1.3 sorry -0.3 4 0.2 -1.3 5 0.2 and 0 6 4.2 3.2 7 5.3 3.9 8 1.5 and 0.7 9 4.7 and 0.1 10 3.3 and 2.2. Here you find MLE's of  $\mu$   $\sigma$  assuming  $x_1, x_2$  follow  $N(2, \mu, \sigma)$ . Find  $Rho$  and test  $H_0: Rho = 0.8$  against  $H_1: Rho \neq 0.8$  using asymptotic test for  $Rho$ .

In the next lecture, I will introduce the use of this Hotelling's T square etcetera for testing for the mean of the multivariate normal distribution or comparing the means of 2 multivariate normal distribution. We will also consider the problems of classification of observations. So this thing I will be covering in the next lecture.
