

**Partial Differential Equations (PDE) for Engineers:
Solution by Separation of Variables
Prof. Sirshendu De
Department of Chemical Engineering
Indian Institute of Technology, Kharagpur**

**Lecture – 03
Principle of Linear Superposition**

In the last class, we have seen that how we have got, we can categorize the problems; get down the problems, into sub problems, by considering one homogeneity at a time. So, in fact, we have seen the how the sub problems can be divided, in case of a parabolic partial differential equation as a example that we have discussing in the last class. And we have found out that, by in the process of breaking down we have identified 3 sources of non homogeneity in the governing equations. And we have we broke down the problem into 3 sub problems, considering one on homogeneity time. That is resulted into one sub problem that will be, that was well posed. And 2 sub problems those are the ill posed problem.

So, all the sub problem, sub problems containing the non 0 or 1 on homogeneous initial condition, and the homogeneous boundary conditions are called the well posed problem. And the sub problems having the homogeneous initial condition and non homogeneous at least 1 on homogeneous boundary condition is known as the ill posed problem. Now in this class we will be looking into, how the ill posed problem converted into a well posed problem, and then we can directly go ahead with the separation of variable type of solution. So, let us consider 1 ill posed problem.

(Refer Slide Time: 01:39)

ill posed Problem:
 $\frac{\partial u_3}{\partial t} = \frac{\partial^2 u_3}{\partial x^2}$ w
 at $t=0$, $u_3=0$; at $x=0$, $u_3=0$ & at $x=1$, $u_3=3$
 $[u_3(x,t) = u_{3t}(x,t) + u_{3s}(x)]$
 $\frac{\partial}{\partial t} (u_{3t} + u_{3s}) = \frac{\partial^2}{\partial x^2} (u_{3t} + u_{3s})$
 $\Rightarrow \frac{\partial u_{3t}}{\partial t} + 0 = \frac{\partial^2 u_{3t}}{\partial x^2} + \frac{d^2 u_{3s}}{dx^2}$
 $\therefore u_{3s}: \boxed{\frac{d^2 u_{3s}}{dx^2} = 0} \quad | \quad u_{3t}: \boxed{\frac{\partial u_{3t}}{\partial t} = \frac{\partial^2 u_{3t}}{\partial x^2}}$

Sub problems that we have considered last time. So, $\frac{\partial u_3}{\partial t}$ is equal to $\frac{\partial^2 u_3}{\partial x^2}$. And at t is equal to 0, we had u_3 equal to 0, at x is equal to 0, we had u_3 equal to 0. and at x is equal to 1, we had u_3 is equal to 3. So, again this problem has to be divided into 2 sub problems, 1 is the, 1 is time dependent another is the time independent solution. So, therefore, u_3 will be divided into, $u_3 t$ will be divided into the into 2 sub problems, 1 is $u_3 t$ transient, which will be function of both x and t , and $u_3 s$ study state which will be function of x only.

So, if so, we divide this problem into 2, this sub problems into another 2 sub parts, 1 is the time independent part, which will be function of x only, another is the time dependent part, which will be function of x and t both. So, in this case, what will be doing, we will be we substitute, this solution into the governing equation. So, this is the mother problem for this particular 2 sub problems $u_3 t$ & $u_3 s$. So, how will be getting the governing equation of $u_3 t$ and $u_3 s$, we will be substituting back, this equation into the mother problem.

So, if you really do that this becomes $\frac{\partial}{\partial t}$ of $u_3 t$ plus $u_3 s$, plus $\frac{\partial^2}{\partial x^2}$ is equal to $\frac{\partial^2}{\partial x^2}$ and u_3 substitute $u_3 t$, plus $u_3 s$. now let us look into this what it is. So, $\frac{\partial}{\partial t}$, this becomes $\frac{\partial u_3 t}{\partial t}$, because u_3 is the function of x and t both, plus $u_3 s$ which is a sole function x it is time independent part. So, it is a sole function of x . So, time derivative will be 0. So, this will be 0 is equal to $\frac{\partial^2 u_3 t}{\partial x^2}$,

that term remain same because a $u_3 t$ is the function of x and t both, plus u_3 is a sole function of x , it is not a function of time. So, therefore, this partial derivative will be a total derivative in this case. So, it will be $d^2 u_3 / dx^2$.

Now, next what we will be doing, we will be collecting the similar terms and formulate the governing equation of $u_3 t$ and $u_3 s$. So, there is only $u_3 t$, $u_3 s$ is coming. So, therefore, the governing equation of $u_3 s$, is $d^2 u_3 s / dx^2$ it will be equal to 0. and we need to have 2 boundary conditions, and what is the governing equation of $u_3 t$. So, governing equation of $u_3 t$ is, $\partial u_3 t / \partial t$, is equal to $\partial^2 u_3 t / \partial x^2$. So, this is the governing equation of $u_3 s$, and this is the governing equation of $u_3 t$.

Next what we will be doing, we will be setting up the boundary conditions and the initial conditions of $u_3 s$, and $u_3 t$. So, first we will be looking into the boundary conditions of $u_3 s$. what will be doing the boundary conditions of $u_3 s$, and $u_3 t$ will be satisfying the original boundary condition of the mother problem. So, let us look into the original problem.

(Refer Slide Time: 05:42)

Handwritten mathematical derivation on a whiteboard:

- At $x=0$, $u_3 = 0 \Rightarrow u_{3t} + u_{3s} = 0$
- At $x=0$, $u_{3s} = 0$ ✓
- At $x=0$, $u_{3t} = 0$
- At $x=l$, $u_3 = 3$
- $\Rightarrow u_{3t} + u_{3s} = 3$
- At $x=l$, $u_{3s} = 3$
- At $x=l$, $u_{3t} = 0$
- $\frac{d^2 u_{3s}}{dx^2} = 0 \Rightarrow \frac{du_{3s}}{dx} = C_1 \Rightarrow u_{3s} = C_1 x + C_2$
- $x=0$, $u_{3s} = 0$
- $C_2 = 0$
- $u_{3s} = C_1 x$
- At $x=l$, $u_{3s} = 3 \Rightarrow 3 = C_1$
- $u_{3s} = 3x$

In the original problem, at x is equal to 0. Our u_3 is equal to 0. So, what is u_3 , u_3 is nothing, but $u_3 t$ plus $u_3 s$, is equal to 0; that means, at x is equal to 0, both of this quantities will be equal to 0 so; that means, x is equal to 0, I have $u_3 s$ equal to 0, and at x is equal to 0, I have $u_3 t$ is equal to 0.

So, that sets the boundary condition at x is equal to 0. then at x is equal to 1, in my original problem u_3 was 3, u_3 was 3; that means, $u_3 t$ plus, $u_3 s$ is equal to 3. Now what I will do, I will be judiciously selecting I will be associating the non homogeneous part, with the time independent solution. And if I do that, then my $u_3 t$ will be 0, at the boundary at x equal to 0, x equal to 1.

So, what is our my aim, why we have doing this, our aim is to get a non homogeneous initial condition and homogeneous boundary conditions for a partial differential equation to make it well posed. In order to achieve that I will be judiciously associating the non homogeneous part of the boundary condition, to the time varying part only making or forcing the boundary condition of the transient part, or the partial differential equation part to be homogeneous. So, if I do that then I can write at x is equal to 0, my $u_3 s$ equal to 3, at x is equal to 0, my $u_3 t$ is equal to 0.

So, that makes that satisfies the boundary condition of the original problem as well. So, these 2 boundary conditions will be good enough, to solve the space varying part. So, therefore, what is the space varying part? If you look into the solution of governing equation of the space varying part $d^2 u_3 s / dx^2$ is equal to 0. So, therefore, what is the solution of this? $D u_3 s / dx$ is a constant, and 1 more integration $u_3 s$, is equal to $c_1 x + c_2$. So, if you put this to boundary condition that x is equal to 0, $u_3 s$ is equal to 0, the first boundary condition x is equal to 0 $u_3 s$ is equal to 0, that will give you c_2 equal to 0; that means, $u_3 s$ should be is equal to $c_1 x$.

Now, we apply the second boundary condition, at x is equal to 1. So, this is x is equal to 1, this is also at x is equal to 1, because this is at x equal to 1. So, there is a mistake there. So, $u_3 s$ is equal to $c_1 x$. So, at x is equal to 1 $u_3 s$ is equal to 3. So, if you put that, then it becomes 3 is equal to c_1 and therefore, $u_3 s$ is nothing, but $3 x$ this is the solution of $u_3 s$. So, u_3 is equal to $3 x$. So, you have got the complete solution of the time, of the space varying part or the time independent part.

Now, with this we will be formulating the governing equation of the, initial condition of the time varying part or $u_3 t$. So, what is $u_3 t$?

(Refer Slide Time: 09:31)

$at \ t=0, \ u_3 = 0$
 $\Rightarrow u_{3s}(x) + u_{3t}(x,t) = 0$
 $\therefore u_{3t} = -u_{3s}(x) = -3x$

$$\frac{\partial^2 u_{3t}}{\partial t^2} = \frac{\partial^2 u_{3t}}{\partial x^2}$$

$at \ t=0, \ u_{3t} = -3x$
 $at \ x=0, \ u_{3t} = 0$
 $at \ x=1, \ u_{3t} = 0$

Well Posed

$u_3 = u_{3s}(x) + u_{3t}(x,t)$

In the original problem at t is equal to 0, u_3 was equal to 0. So, therefore, u_3 is nothing, but u_3 is which will be a sole function of x , plus u_3 t , which will be a function of both x , and t must be equal to 0. So, we write u_3 t should be is equal to minus u_3 s , there is x . now what is u_3 s x that is the steady state solution. And we know the steady state solution. What is the steady state solution we just found out, that u_3 is equal to nothing, but $3x$. So, u_3 t will be nothing, but minus $3x$. So, that makes my boundary condition the initial condition to be non-homogeneous, and the problem is now well posed problem.

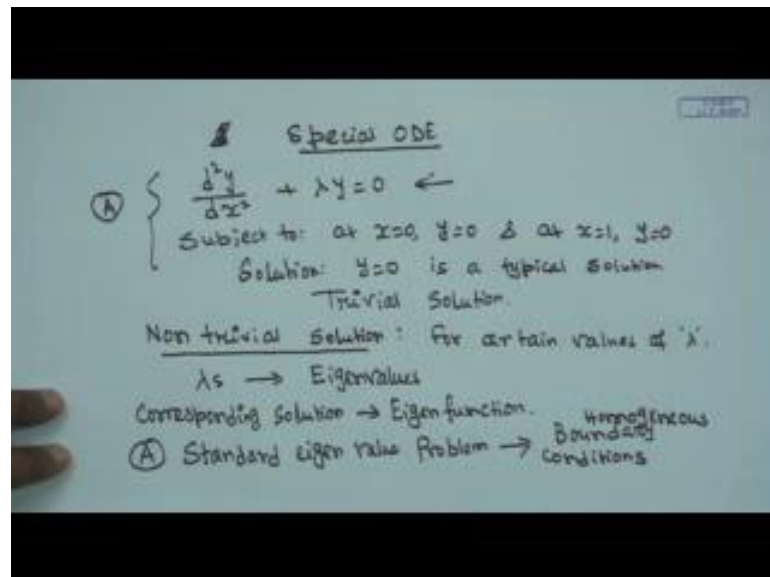

Now, we define the problem write down the problem completely. $\frac{\partial^2 u_3}{\partial t^2} = \frac{\partial^2 u_3}{\partial x^2}$ at t , is equal to 0 my u_3 t , is equal to minus $3x$, at x is equal to 0 u_3 t is equal, to 0 and at x is equal to 1 u_3 t is equal to 0. So, this makes the problem completely well posed, with a non homogeneous or non 0 initial condition and homogeneous boundary conditions.

So, that is how an ill posed problem can be converted into a well posed problem, by further sub dividing in into 2 sub problem. 1 is the time dependent part another is the time independent part. So, once we do that ah, we can use the principle of linear super position. So, u_3 will be now the solution, u_3 will be a solution of u_3 s , which will be the function of x , plus u_3 t which will be function of x , and t both by solving this. We already saw this part this is nothing, but $3x$ in our example. And u_3 t is the complete

solution of this by using separation of variable, that will be look into later on, but before into going into going down to the separation of variable, we have to define the you know some special functions.

Now, we have to define the eigenvalue problem or Sturm-Liouville problem and then we will be looking into the several properties and theorems to satisfy this Sturm-Liouville problem or standard eigenvalue problem, will be satisfying. Then, we will be going to the separation of solution by separation of variable directly. So, what will be doing next is that, we will be looking into a special type of function.

(Refer Slide Time: 12:28)

For example d^2u , special ODE, first we will looking into a ODE in the form of d^2x y d^2x plus λy is equal to 0. Subject to at x is equal to 0, y is equal to 0 and at x is equal to 1, y is equal to 0.

So, both boundary conditions are homogeneous, in this particular type of ordinary differential equation. So, what is the solution of this ordinary differential equation, the solution is y equal to 0, is a solution. Solution must be satisfying the governing equation as well as the boundary condition. So, if y is equal to 0, that will be satisfying the governing equation as well as the boundary condition, but this is not a solution, this is known as a trivial solution. So, y equal to 0 is known as a trivial solution.

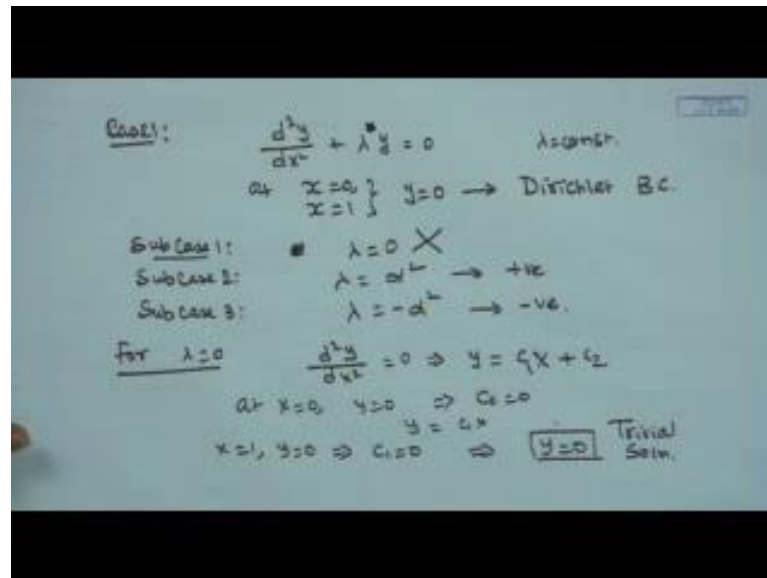

So, what is a next question? The next question is, is their existence of non trivial

solution. So, if so, so there may be a certain value of λ the parameter that is a constant parameter that will be appearing in the governing equations. There may be some kind of λ , that will be existing for which the governing equation, becomes you know satisfied, that is called a non trivial solution. So, let us look into the non trivial solution. Non trivial solution can be obtained for certain values of λ , the constant. These values of λ are known are the eigenvalues of the problem, and the corresponding solutions are known as the Eigen functions, and whenever we will be we will be we will be talking about these type of problem, $d^2 x^2 + \lambda y$ λ is a constant. And the boundary conditions are homogeneous this is a, these type of problem is known as a standard eigenvalue problem.

So, this λ is known as the eigenvalue. And the corresponding solution is known as the Eigen function. And whenever we talk about an equation like this, and the homogeneous boundary conditions, then this is known as a standard eigenvalue problem. So, this is is a standard eigenvalue problem, or a Sturm-Liouville problem this is a special type of Sturm-Liouville problem. We will be looking into the generalized Sturm-Liouville problem in the next class itself.

So, in a standard eigenvalue problem, the bounded, the necessity is that the form of the equation will be like this. And the boundary conditions have to be homogeneous. So, in a standard eigenvalue problem we should have the boundary conditions homogeneous. So, we should have homogeneous boundary conditions. So, next what we will be doing, we will be looking into the solution of this type of equation. And we will be identifying the eigenvalues and Eigen functions, and sees how these eigenvalues and Eigen functions, they change for different kinds of boundary conditions.

(Refer Slide Time: 16:48)

Now, first type of problem, we solve is a case 1, case 1, will be $d^2y/dx^2 + \lambda y = 0$. Let say λ ; λ is the constant. And at x is equal to 0, we have and x is equal to 1, both the boundaries we have y is equal to 0, this is a case of Dirichlet boundary condition. Now the parameter λ will have 3 options, λ can be 0, λ can be positive, λ can be negative.

So, we will be looking all the cases 1 by 1. So, sub case 1 λ is equal to 0. So, let us look into in the sub case 2, will be λ is positive λ is equal to α^2 , and sub case 3, and will be λ is negative. So, λ is minus α^2 . So, λ 0, positive, and this are negative. So, let us go by case by case, for λ is equal to 0. Let us see what happens to a solution. Our solution is $d^2y/dx^2 = 0$ in that case, $y = c_1x + c_2$.

So, now let us put the boundary condition at x is equal to 0, y is equal to 0. So, first boundary condition x is equal to 0, y is equal to 0, this gives you $c_2 = 0$. So, solution is $y = c_1x$ at x is equal to 1, y is equal to 0 indicates $c_1 = 0$. So, $y = 0$. So, this gives a trivial solution. So, trivial solution is not accepted. So, the sub case is not tenable it is not agreeable. So, therefore, λ cannot be equal to 0. So, sub case 1 is ruled out, and λ cannot be equal to 0.

So, next let us look into the other one λ is negative let us look into the sub case 3.

(Refer Slide Time: 19:28)

Subcase 3 $\lambda = -\alpha^2$
 $\frac{d^2 y}{dx^2} - \alpha^2 y = 0$
 $y = C_1 \exp(\alpha x) + C_2 \exp(-\alpha x)$
 at $x=0, y=0$
 $0 = C_1 + C_2 \Rightarrow C_1 = -C_2$
 $x=1, y=0$
 $0 = C_1 e^\alpha + C_2 e^{-\alpha}$
 $0 = C_2 [e^\alpha - e^{-\alpha}]$
 $C_2 = 0; C_1 = 0$ y=0 Trivial Solution

A graph on the right shows two exponential curves: $e^{\alpha x}$ (increasing) and $e^{-\alpha x}$ (decreasing), intersecting at the origin (0,0). The x-axis is labeled x .

Lambda is equal to minus alpha square. So, it becomes $d^2 y / dx^2 - \alpha^2 y = 0$. So, we know the solution will be in the form of $m^2 - \alpha^2 = 0$. So, $m = \pm \alpha$. So, the solution will be $C_1 e^{\alpha x} + C_2 e^{-\alpha x}$.

Now, if you put the value boundary condition. Let us evaluate C_1 and C_2 at $x=0, y=0$. So, $0 = C_1 + C_2$. So, $C_1 = -C_2$. In the next case, what will we do we put the other boundary condition, at $x=1, y=0$. So, $0 = C_1 e^\alpha + C_2 e^{-\alpha}$. So, $C_1 = -C_2 e^{-2\alpha}$. So, therefore, C_2 will be common, $e^{-\alpha} - e^{-\alpha} = 0$.

Now, $e^{-\alpha}$, if you an alpha is a constant, and be a positive, it will be a constant. And if you know what is the variation, of $e^{-\alpha}$, for what is this alpha. So, alpha will be forever positive number. So, this will be $e^{-\alpha}$, what will be $e^{-\alpha}$, this will be $e^{-\alpha}$ and $e^{-\alpha}$ will be like this. So, that difference will be a finite value, and it will be never 0; that means, in this equation, this part can never be equal to 0.

So, what is the option we have left, the option is left, in order to satisfy this equation $C_2 = 0$.

must be equal to 0. Now if c_2 is equal to 0 c_1 is minus c_2 . So, that will also lead c_1 is equal to 0. So, if c_1 and c_2 both are equal to 0, then my solution is 0. So, it is basically again we are landing up with a trivial solution. So, trivial solution is not sort for. So, therefore, λ cannot be negative as well. So, what is the, what is left now the option now left, is λ has to be a positive value, or λ has to be equal to α^2 .

So, let us look into the sub case 2.

(Refer Slide Time: 22:25)

Subcase 2: $\lambda = \alpha^2$

$$\frac{d^2 y}{dx^2} + \alpha^2 y = 0$$

$$y = c_1 \sin(\alpha x) + c_2 \cos(\alpha x)$$

at $x=0$, $y=0$

$$0 = c_2$$

$$y = c_1 \sin(\alpha x)$$

at $x=1$, $y=0 \Rightarrow 0 = c_1 (\sin \alpha)$

$\sin \alpha = 0 \quad \forall c_1 \neq 0$

$\alpha_n = n\pi; \quad n = 1, 2, 3, \dots, \infty$

Eigenvalues are $n\pi$

$y_n = c_1 \sin(n\pi x) \rightarrow n$ th eigenfunction.

That $d^2 y/dx^2 + \lambda y = 0$, λ is equal to α^2 , and governing equation now becomes $d^2 y/dx^2 + \alpha^2 y = 0$. So, as you know, all of us know about it that this particular type, of ordinary differential equation, will be having the solution in terms of the, sin and cosine functions. So, y will be is equal to $c_1 \sin \alpha x$, plus, $c_2 \cos \alpha x$.

Now, let us put down the boundary conditions, and see and evaluates the constants c_1 , and c_2 , and let us look into the what happens to the boundary the solution of y . at x is equal to 0, my y is equal to 0. So, if you put that 0, is equal to $c_1 \sin 0$ is 0. So, that will be gone. So, c_2 cause 0 is 1. So, c_2 equal to 0. So, my solution is y is equal to $c_1 \sin \alpha x$. now at x is equal to 1, put the other boundary. At x is equal to 1, my y is equal to 0. So, therefore, 0 is equal to $c_1 \sin \alpha$. Now in this particular problem if there are 2 options, c_1 is 0 or $\sin \alpha$ is equal to 0. if c_1 is equal to 0 then again will be getting a trivial solution that we are not looking for. So, the other option is for not equal to c_1 , if

we in order to survive the solution, the c_1 has to be non equal non 0 therefore, $\sin \alpha$ to be equal to 0. So, from this $\sin \alpha$ should be equal to 0, for c_1 not equal to 0.

So, what is the solution of $\sin \alpha$ equal to 0, α is equal to $n\pi$, where the index n should runs from 1, 2, 3 up to infinity. In the case n is equal to 0, should be avoided because that will be leading to the first sub case, and will be getting the trivial solution. So, therefore, we write α_n is equal to $n\pi$, a subscript n to the α , in order to find out, order to indicate that, we are talking about the n th root. So, in this equation the root is $n\pi$, and these are the eigenvalues of the system. So, eigenvalues are $n\pi$, and α_n is known as n th eigenvalue, n th eigenvalue.

So, what is the n th Eigen function, y_n ? So, we substitute put a substitute n in order to indicate this is the n th Eigen function, corresponding to n th eigenvalue. So, y_n will be nothing, but $c_1 \sin n\pi x$. So, this is the n th Eigen function. So, so we have seen the in this particular problem, that if we have dirichlet boundary conditions, on the both boundaries, then for α is equal to $n\pi$, we will be having the eigenvalues, and for corresponding Eigen function, will be $\sin n\pi x$. if we have this α_n is equal to $n\pi$, then only you will be having a non trivial solution for this particular system.

Next what we will be doing, we will be formulating the problem by changing the boundary conditions into Neumann, and into the robin mixed, and see how the eigenvalues and the Eigen functions will involve.

So, I will stop in this class. In the next class what I will be doing, I will be taking up this problem again, with by changing the boundary conditions into Neumann. And then I will be taking up a problem another problem, with by changing the boundary condition into robin mixed. And see how the Eigen functions and eigenvalues will be taking up the shape, and I will be getting the various types of Eigen solutions, for such a well posed, Eigen standard eigenvalue problem.

Thank you very much.
