**Lecture – 06  
Generalized Sturm – Liouville Problem**

Welcome to this session. In this class, we will be looking into the standard Eigen value problem, or the Sturm - Liouville problem and its property; and, we will be looking into a generalized problem.

(Refer Slide Time: 00:31)

Let us consider the operator, general operator  $L$  as  $L u$  equal to  $a_0 x$  square  $u$  double prime, plus  $a_1 x$   $u$  prime, plus  $a_2 x u$ . So, let us consider this operator, and on separation of variable, we may be getting a relationship like this;  $a_0 u$  double prime, plus  $a_1 u$  prime, plus  $a_2 u$ , plus  $\lambda a_3 u$  is equal to 0, and where  $\lambda$  is a constant.

Let us assume the digital boundary condition that, at  $x$  is equal to 0, and  $x$  is equal to 1, we have  $u$  is equal to 0. Now, this equation can be written in a compact form as  $L u$  plus  $\lambda a_3 u$  is equal to 0; or, it will be written in the form of  $L u$  is equal to minus  $\lambda a_3 u$ .

Now, if you look into the formation of this equation, the form of this equation, the equivalent notation in the matrix algebra in the discrete domain, this is the continuous domain; we are talking about the functions, continuous functions. Now, in the discrete domain, in the matrix, if you look into the similar form of equation, similar form corollary is that, for matrices, the similar type of equation, we can see as  $A x$  is equal to  $\lambda x$ ; and, this is known as Eigen value problem. Therefore, in case of the continuous domain for functions, this is a standard Eigen value problem.

So, let us consider this is as equation 1. Now, this equation 1 can be rewritten in this form; means, equation 1 can be rewritten as  $\frac{d}{dx} (p \frac{du}{dx}) + q x u + \lambda r x u = 0$ . So, this is the end of it, plus  $q x u$ , plus  $\lambda r x u$ , is equal to 0. Now, this equation can be written in this form, where we will be defining  $p x$ ,  $q x$  and  $r x$ , in terms of the original coefficient  $a_0$ ,  $a_1$ ,  $a_2$  and  $a_3$ .

(Refer Slide Time: 03:46)

$$\begin{aligned}
 p(x) &= e^{\int \frac{a_1(x)}{a_0(x)} dx} \Rightarrow \ln p = \int \frac{a_1(x)}{a_0(x)} dx \\
 q(x) &= \frac{a_2(x)}{a_0(x)} p \Rightarrow \frac{1}{p} \frac{dp}{dx} = \frac{a_1}{a_0} \\
 r(x) &= \frac{a_3(x)}{a_0(x)} p \\
 \cancel{L} \frac{d}{dx} \left( p \frac{du}{dx} \right) + q u + \lambda r u &= 0 \\
 \Rightarrow p \frac{d^2 u}{dx^2} + \frac{dp}{dx} \frac{du}{dx} + q u + \lambda r u &= 0 \\
 \Rightarrow p u'' + \frac{a_1}{a_0} p u' + \frac{a_2}{a_0} p u + \lambda \frac{a_3}{a_0} p u &= 0 \\
 \Rightarrow \cancel{L} a_0 u'' + a_1 u' + a_2 u + \lambda a_3 u &= 0 \\
 \Rightarrow L u = -\lambda a_3 u &
 \end{aligned}$$

So, let us define that,  $p x$  is nothing, but  $e$  to the power integral  $a_1 x$  divided by  $a_0 x$ ,  $d x$ ;  $q x$  is equal to  $a_2 x$  over  $a_0 x$ , times  $p$ ; and,  $r x$  is equal to  $a_3 x$  divided by  $a_0$  as the function of  $x$ , times  $p$ . So, if you define, this equation can be, if you define this quantities  $p$ ,  $q$  and  $r$  in the equation number 1, then you will be getting back the equation 1. This is very simple, very, you know, simplified case. So, if we take the logarithm of both side, and then, differentiate; so,  $\ln p$  is equal to integral  $a_1 x$  divided by  $a_0 x d x$ . So, if you differentiate it, you will be getting,  $\frac{dp}{dx} \frac{1}{p}$  is equal to  $\frac{a_1}{a_0}$ .

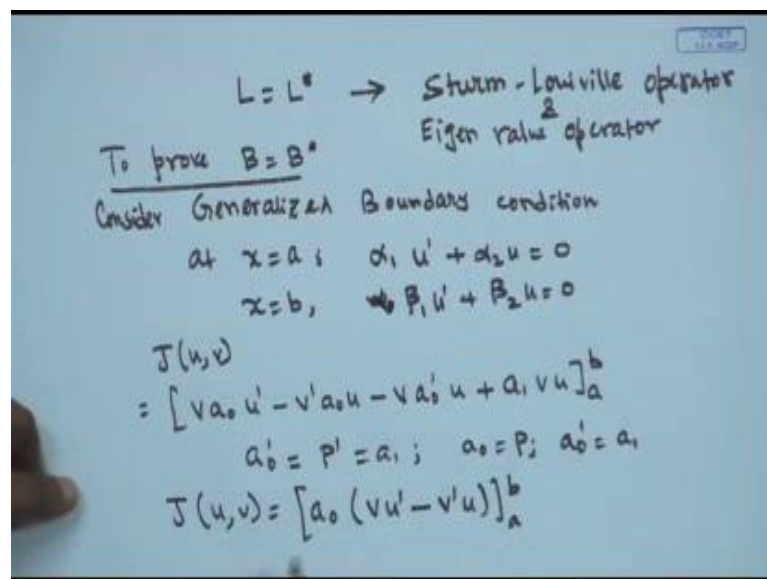

prime, plus a 0 double prime, minus a 1 prime, plus a 2 times v. This you have already proved earlier.

In the last class, we have proved this. Now, if you compare a 0, a 1 and other things. So, if you compare this one, this equation number, equation number 3 with 4, that we have already seen earlier that, a 0 is nothing, but p of x. Therefore, a 1 is nothing, but d p d x, and a 2 is equal to q of x. So, L star v is nothing, but p v prime double prime, plus 2 p prime, minus p prime, times v prime, plus p double prime, minus p double prime, plus q is equal to, into v. So, therefore, this becomes p v double prime, plus p prime v prime, plus q times v.

So, therefore, you can always see that, L star is equal to L. So, L star will be nothing, but what is L star? L star is p d square d x square, plus d p d x times p prime d d x, plus q. So, this will be nothing, but d d x of p d d x, plus q. So, if you see that, L is equal to nothing, but L star. So, L is equal to this, and L star is equal to this.

(Refer Slide Time: 10:15)

So, L is equal to L star, and our general Sturm - Liouville operator or Eigen value operator is a self adjoint operator; operator, in general, is where L is equal to L star. Now, we will see that, to prove B is equal to B star, and if we, if we want to prove B is equal to B star, we have to, we have to check, let us say, a generalized boundary condition. Consider a generalized boundary condition. This will be no longer a (Refer Time: 11:13) boundary condition; consider a generalized boundary condition that, at x is

equal to a, we have  $\alpha_1 u' + \alpha_2 u = 0$ ; and, at  $x = b$ , we have  $\beta_1 u' + \beta_2 u = 0$ .

And then, we will be looking into the bilinear concomitant. If we look into the bilinear concomitant, this becomes  $v a_0 u' - v' a_0 u$ , evaluated on the two boundaries  $a$  and  $b$ . Now, we have already proved that,  $a_0 u' = d p d x$ , is nothing, but  $p u' = a_1$ , and  $a_0 u = p$ , and  $a_0 u' = a_1$ . So, bilinear concomitant now becomes only, you know, it boils down into  $a_0 v$ , multiplied by  $u'$ , minus  $v'$ , multiplied by  $u$ , whole thing evaluated between  $a$  and  $b$ .

(Refer Slide Time: 12:52)

$$J(u, v) = a_0(b) v(b) u'(b) - a_0(b) v'(b) u(b) - a_0(a) v(a) u'(a) + a_0(a) v'(a) u(a)$$

$$J(u, v) = a_0(b) v(b) \left[ -\frac{\beta_2}{\beta_1} u(b) \right] - a_0(b) v'(b) u(b) - a_0(a) v(a) \left( -\frac{\alpha_2}{\alpha_1} u(a) \right) + a_0(a) v'(a) u(a)$$

$$= -a_0(b) u(b) \left[ +\frac{\beta_2}{\beta_1} v(b) + v'(b) \right] + a_0(a) u(a) \left[ \frac{\alpha_2}{\alpha_1} v(a) + v'(a) \right]$$

Now, if you really do that, and substitute the values, let us see what the bilinear concomitant will give us. So,  $J(u, v)$  is nothing, but  $a_0$  at  $b$ ,  $v$  at  $b$ ,  $u'$  at  $b$ , minus  $a_0$  at  $b$ ,  $v'$  at  $b$ ,  $u$  at  $b$ , minus  $a_0$  evaluated at  $a$ ,  $v$  at  $a$ ,  $u'$  at  $a$ , minus minus plus,  $a_0$  at  $a$ ,  $v'$  at  $a$ , and  $u$  at  $a$ . We already had the boundary condition of the original problem as that, at  $x = a$ , we had  $\alpha_1 u' + \alpha_2 u = 0$ . So, we can substitute at  $x = a$ ,  $u' = -\frac{\alpha_2}{\alpha_1} u$ . So,  $u'$  at  $a$ , we can substitute; and then, at  $x = b$ , we have  $\beta_1 u' + \beta_2 u = 0$ . So, you can substitute these two.

So,  $J(u, v)$  will be nothing, but  $a_0$  at  $b$ ,  $v$  at  $b$ ; and  $u'$  at  $b$  will be nothing, but minus  $\alpha_2$  by  $\alpha_1 u$  at  $b$ , minus  $a_0$  at  $b$ ,  $v'$  at  $b$ ,  $u$  at  $b$ , and minus  $a_0$  at  $a$ ,  $v$  at  $a$ ,

and  $u'$  at  $a$ ; we substitute, this was  $u'$  at  $b$ . So, this will be  $\beta_2$ ; this will be nothing, but this will not be  $\beta_2$ ;  $\alpha_2$ ;  $\alpha_2$ , and this is  $\beta_2$  and  $\beta_1$ , and,  $u'$  at  $a$  will be  $-\alpha_2$  by  $\alpha_1$  times  $u$  at  $a$ , minus plus  $a_0$  at  $a$ ,  $v'$  at  $a$ , and  $u$  at  $a$ . Now, we can collect the terms.

For example, we can take  $a_0$  and  $u$  common from this one, from the first two terms. So, if you really do that,  $a_0$  and  $u$  at  $b$ , we take it common. So, what is remaining is,  $-\beta_2$  by  $\beta_1$ ,  $v$  at  $b$ , minus; you can take minus also common, from first two, first two terms. So, it will be  $+\beta_2$  by  $\beta_1$ ,  $v$  at  $b$ , plus  $v'$  at  $b$ . And, we can take  $a_0$ ,  $a$  as common; minus, minus, plus. So, it will be  $+\alpha_0$  at  $a$  common and  $v$  and  $u$  at  $a$  common. So, if you do that, what you will be getting is  $\alpha_2$  by  $\alpha_1$ ,  $u$  at  $a$ , plus  $v$ , sorry,  $v$  at  $a$ , then, plus  $v'$  at  $a$ .

(Refer Slide Time: 16:30)

$$B^* \begin{cases} \text{at } x=a, \frac{\alpha_2}{\alpha_1} v + v'(a) = 0 \\ \Rightarrow \alpha_1 v' + \alpha_2 v = 0 \\ \text{at } x=b, \beta_1 v' + \beta_2 v = 0 \end{cases} \quad \left. \vphantom{B^*} \right\} \text{To make } J(u,v) = 0$$

$$\begin{cases} B = B^* \\ L = L^* \end{cases} \quad \text{for a generalized eigenvalue problem.}$$

$$L = a_0 \frac{d^2}{dx^2} + a_1 \frac{d}{dx} + a_2 \quad \rightarrow \text{Sturm-Liouville Problem}$$

$$\boxed{Lu + \lambda a_3 = 0}$$

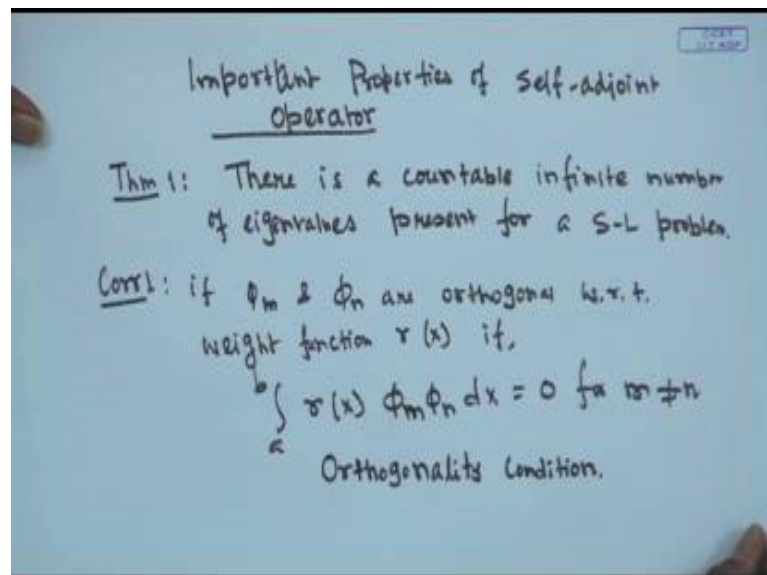

Now, if I select this equal to 0, this boundary, at this boundary,  $x$  is equal to  $b$ , and at this boundary  $x$  equal to  $a$ , this whole thing is common. Let us see what you get in order. So, if you really select that, then bilinear concomitant will vanish. So, at  $x$  is equal to  $a$ , if you select  $\alpha_2 v$ , plus  $v'$  at  $a$  divided by  $\alpha_1$  is equal to 0. So, that will give me  $\alpha_1 v'$ , plus  $\alpha_2 v$  is equal to 0 at  $x$  is equal to  $a$ . and, at  $x$  is equal to  $b$ , I will be getting  $\beta_1 v'$ , plus  $\beta_2 v$  will be 0, to make bilinear concomitant to vanish. So, these will be now my  $B^*$ , or boundary condition of the adjoint problem.

Now, we have to see that,  $B$  is equal to  $B^*$ , and we have already proved  $L$  is equal to  $L^*$  for a generalized Eigen value problem. So, the standard Eigen value problem operator is a self adjoint operator. So, a 0 d square d x square, plus a 1 d d x, plus a 3. So, this will be, if this is the form, then,  $L u$  is equal to plus lambda a 1; this will be a 2 plus lambda a 3 will be 0. So, this is a standard Eigen value problem, and in this standard Eigen, these are generalized form of standard Eigen value problem, or it is also known as the Sturm - Liouville problem.

And, we have proved that, a Sturm - Liouville is nothing, but a self adjoint problem. So,  $L$  is equal to  $L^*$ , and  $B$  is equal to  $B^*$  in this particular case, and we are having a self adjoint operator with us. Now, by establishing the Sturm - Liouville problem, or standard Eigen value problem is a self adjoint problem, is self adjoint operator, then, let us see. What are the various properties of the self adjoint problem we can exploit, for using separation of variable? Now, there are certain salient problems, of the standard Eigen value problem are there, for the self adjoint operator, the important properties of self adjoint operators, perator we should look into.

(Refer Slide Time: 19:04)

So, the first property that goes as a theorem number 1 is that, there is a countable infinity, infinite number of Eigen values present for a Sturm - Liouville problem. So, the number of Eigen values present in the system is infinite in number. So, therefore, we will be talking about infinite dimension on space, and it is basically a fun continuous function

having infinity, infinite dimension. So, number of Eigen function, Eigen values will be infinite, and number of Eigen functions will be infinite.

Then, the next important theorem is that, the Eigen with the; if  $\phi_m$ , this is the corollary 1 is that, if  $\phi_m$  and  $\phi_n$  are orthogonal with respect to weight function  $r(x)$ . So, this is a definition of orthogonal functions;  $\phi_m$  and  $\phi_n$  are the two functions which are said to be orthogonal with respect to each other, and with the weight function  $r$ , then, if this equation is satisfied, integral  $a$  to  $b$   $r(x)$ , multiplied by  $\phi_m$ , multiplied by  $\phi_n dx$  is equal to 0. So, for  $m$  not equal to  $n$ . So, this is known as the orthogonality condition.

So, next, what we will be showing, next theorem that, for if  $\lambda_m$  and  $\lambda_n$  are the two distinct Eigen values of the Sturm - Liouville problem with the Eigen functions  $y_m$  and  $y_n$ , then  $y_m$  and  $y_n$  are orthogonal functions with respect to weight function  $r$ .

(Refer Slide Time: 22:01)

Thm 2: If  $\lambda_m \neq \lambda_n$  are 2 distinct real eigen values with eigen functions  $y_m$  &  $y_n$  then  $y_m$  &  $y_n$  are orthogonal functions w.r.t.  $r(x)$

Proof: SL eqn:  
 $Ly = -\lambda r y$  subj to  $B=0$   
 $b \leq x \leq a$

(1)  $Ly_n = -\lambda_n r y_n$   
 (2)  $Ly_m = -\lambda_m r y_m$

$$\int y_n Ly_m dx - \int y_m Ly_n dx = -\lambda_m \int r y_m y_n dx + \lambda_n \int r y_m y_n dx = (\lambda_n - \lambda_m) \int r y_m y_n dx$$

So, let us look into the theorem, and look into its proof. So, next theorem, which will be quite important to us is that, if  $\lambda_m$  and  $\lambda_n$  are two distinct Eigen values, this is important, two distinct Eigen values, with Eigen functions  $y_m$  and  $y_n$ , then,  $y_m$  and  $y_n$  are orthogonal functions with respect to weight function  $r(x)$ . So, let us prove this theorem. So, proof goes like this. The Sturm - Liouville equation becomes  $Ly$  is equal to minus  $\lambda r y$ , where  $r$  is a function of  $x$ , subject to boundary condition  $b$  is equal to 0, where the domain of  $x$  is lying between  $b$  and  $a$ .

Since  $\lambda_m$  and  $\lambda_n$  are the Eigen values with the Eigen functions  $y_m$  and  $y_n$ , they will be satisfying this equation. So, I can write  $L y_n$  is equal to  $-\lambda_n r y_n$ ;  $L y_m$  should be is equal to  $-\lambda_m r y_m$ . then, what we will be doing, we will be multiplying equation 1 with respect to  $y_m$ ; multiplying equation two with respect to  $y_n$ , and integrate, and subtract. So, what I will do next is, integral of  $y_n L y_m dx$ , minus  $y_m L y_n dx$ . So, this becomes  $-\lambda_m r y_m y_n dx$ ; minus minus plus,  $\lambda_n r y_m y_n dx$ . So, we will be getting on the right hand sides as  $\lambda_n$  minus  $\lambda_m$  integral  $r y_m y_n dx$ .

So, next, what will we, we invoke the property of the adjoint operator, and if you look into the property of the adjoint operator that, integral of  $u L v$  is nothing, but integral of  $L^* u v$ , plus  $J u v$ .

(Refer Slide Time: 25:05)

$$\begin{aligned}
 u &= y_n \\
 v &= y_m \\
 \int u L v &= \int L^* u v + J(u, v) \\
 \int y_m L y_n dx + J(y_m, y_n) &= \int y_m L y_n dx \\
 L = L^* \text{ \& } J(y_m, y_n) &= 0 \\
 \int y_m L y_n dx - \int y_m L y_n dx &= (\lambda_n - \lambda_m) \int r y_m y_n dx \\
 \Rightarrow \frac{(\lambda_n - \lambda_m)}{\neq 0} \int r y_m y_n dx &= 0 \\
 \therefore \int r y_m y_n dx = 0 \parallel \Rightarrow & \text{Eigenfunctions are orthogonal w.r.t weight function } r(x)
 \end{aligned}$$

We utilize this property, and we put down the first integral  $y_n L y_m dx$  as integral  $y_m L^* y_n dx$ , plus  $J y_m y_n$ , minus integral  $y_m L y_n dx$  is equal to, right hand side is  $\lambda_n$ ,  $\lambda_n$  minus  $\lambda_m$ , integral  $r y_m y_n dx$ . So, what I do? I put  $y_u$  is equal to  $y_n$ ;  $u$  is equal to  $y_n$ , and  $v$  is equal to  $y_m$ . So, then, expanded the first function in terms of its adjoint variable. So, in terms, I just wrote this one in terms of adjoint operator, in the form of this and we will be getting this. So, we have already proved that Sturm - Liouville operator is  $L$  is equal to  $L^*$ ; it is a self adjoint operator.

So, and,  $\int y_m y_n dx$  is equal to 0, that we have already proved earlier that, Sturm - Liouville operator is a self adjoint operator. Using that condition, we can write  $\int y_m L y_n dx$  is equal to  $\int L^* y_m y_n dx$ . So,  $\int y_n L y_m dx$ , minus  $\int y_m L y_n dx$ , is equal to  $(\lambda_n - \lambda_m) \int r y_m y_n dx$ . And, this was of because of this, and these two will be equal and opposite. So, you will be having  $(\lambda_n - \lambda_m) \int r y_m y_n dx = 0$ . So,  $\lambda_n$  and  $\lambda_m$  are two distinct Eigen values. So,  $\lambda_n \neq \lambda_m$ . So, this cannot be equal to 0. So, what is left is, this integral has to be equal to 0.

So, therefore,  $\int r y_m y_n dx = 0$ . So, what this means, this means that, Eigen functions are orthogonal functions; are orthogonal with respect to weight function  $r(x)$ . This is known as the weight function. So, let us summarize whatever we have done, we have looked. We have defined a standard Eigen value problem, and we have looked into the properties of the standard Eigen value problem, and we have proved that standard Eigen value problem, or Sturm - Liouville problem is a self adjoint operator, or self adjoint problem. Here,  $L = L^*$ , and  $B = B^*$ . Then, we have looked into the properties of the standard Eigen value problem, which we will be using quite often in your course.

Number one property is that, it will be having infinite number of Eigen values, and so, it will be talking about infinite dimensional space. So, it will be a, almost a continuous space. So, therefore, second important property is that, the Eigen, if the Eigen values are distinct corresponding to Eigen functions, and if Eigen values are distinct, then, the Eigen functions will constitute a set of orthogonal functions with respect to the weight function  $r$ . if the equation is in the form of  $L u = -\lambda r u$ , then  $r$  can be identified as the weight functions, and the corresponding Eigen functions will be orthogonal to each other, with respect to the weight function  $r$ .

Now, in the Cartesian coordinate system, we have seen the corresponding equation is  $\frac{d^2 y}{dx^2} + \lambda y = 0$ . So, here, the weight function  $r$  is equal to 1, and this equation is a special form of standard Eigen value problem, where  $a_0 = 1$ ,  $a_1 = 0$ , and  $a_2 = 0$ . So, we got the corresponding equation in the Cartesian coordinate system as a subset of the standard Eigen value problem in its general form. So, we have talked about the, we have considered the general form of the standard Eigen value problem, or the Sturm - Liouville problem, and established that, it

is a, it forms a self adjoint, self adjoint system, and we have looked into the various properties of the self adjoint operator. And now, we are in a position to start with the actual problem using separation of variable type of solution.

Thank you very much.
