Comparison test for series

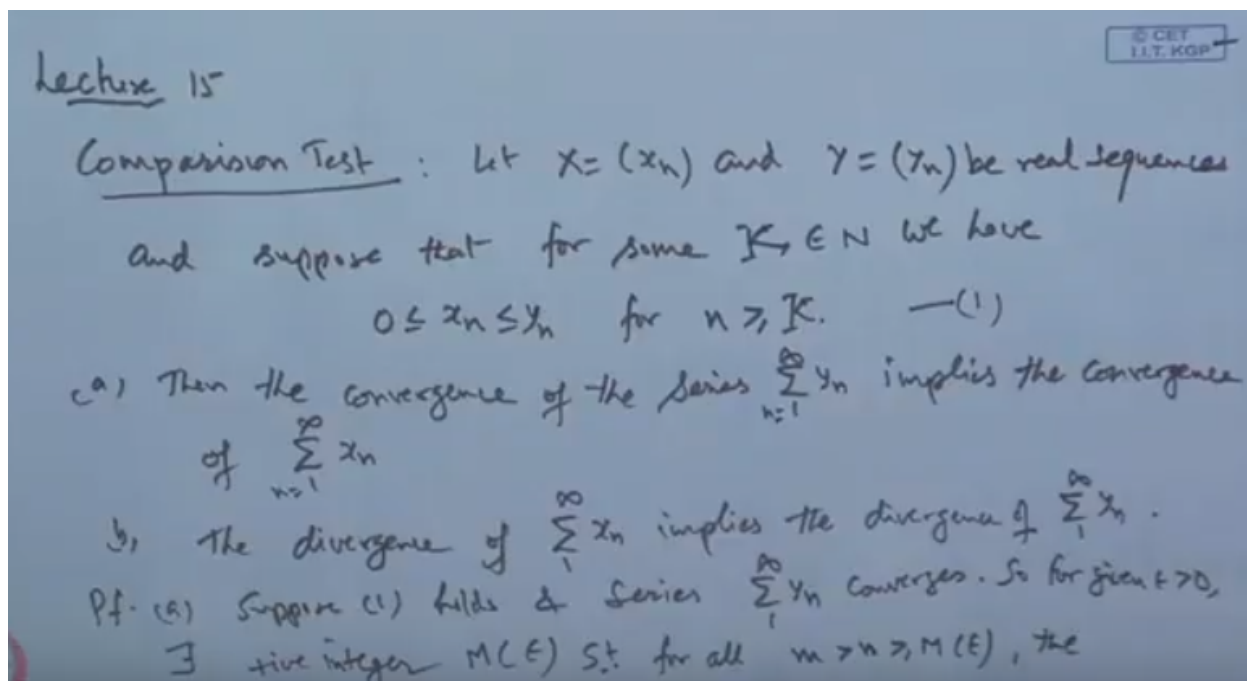

Course

On

Introductory course in real analysis

Okay. So, last time we have discussed the various tests, for the convergence of the series, now in continuation we will do few more tests and discuss few more tests like a comparison test and limit comparison test and after that we will come to the conditional and absolute convergence of the series.

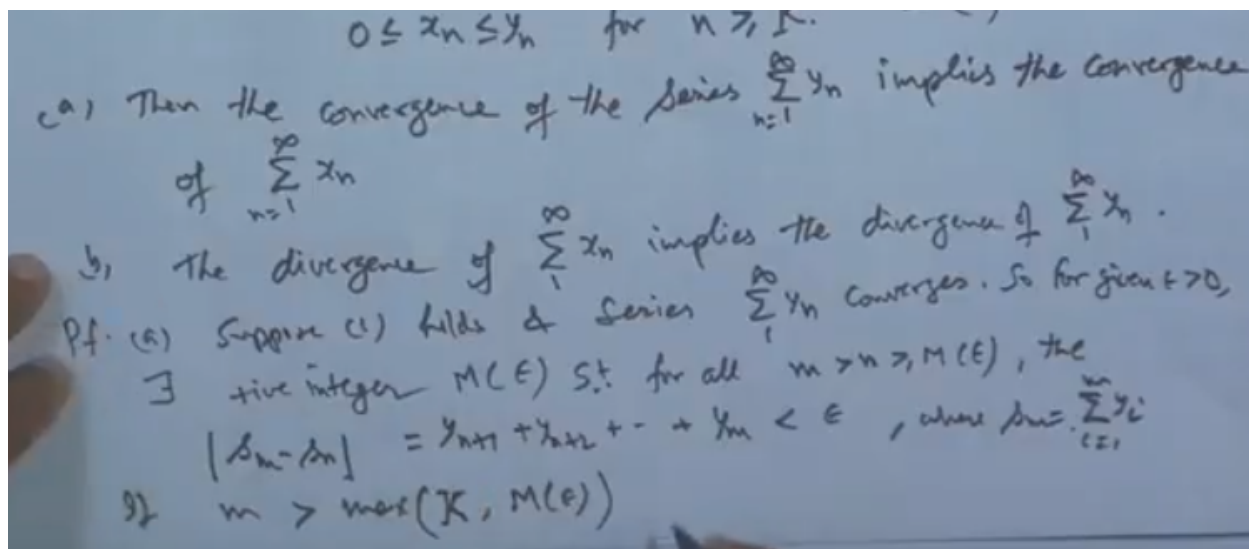

(Refer Slide Time: (0.42))

So first stage to each a in continuation we have another test age which is known as the comparison test, comparison test, the test says, Let X which is X_N and Y, say Y be real sequences, sequences and suppose, and suppose, for suppose that for some K, for some K which is I of course a positive integer, we have this inequality zero is less than equal to x_n less than equal to Y_n and this is valid for N greater than equal to K. it may be true for all ends also if not possible then at least after certain stage if this inequality holds or then, the series the convergence of the series, then the convergence of the series, Sigma by N and is of course 1 to infinity, converges of the series implies, the convergence of, of the series Sigma x_n 1 to infinity, 1 to infinity and the divergence of the series of the series, Sigma x_n n is 1 to infinity implies, the divergence of the series Sigma Y_n , in fact this time we that we have discussed already in case of the sequences, so similar results we have for a sequence of non-negative series we have sequence of the non negative terms, all terms are non negative so what the comparison test says if we are having a series say Sigma n of each terms is non-negative then the to discuss the convergence of the series to find out the nature of the series Sigma x_n if we are able to identify some sequence by n for which this less and 0 is less than equal to x_n less than equal to y_n holds for either for all n, all may be after certain stage, then the convergence of this by n will implies the convergence of the series Sigma, except it means that with the help of x_n if we find out a suitable y_n for which the convergence of the series Sigma y_n natural is known then one can easily establish the convergence so by, and in case if this reason is true but if the series is divergent Sigma x_n then the divergence of by hand will be there, it means if we are interested to know the one and we expect or something that that series is diverging then we have to find this race we have this is diverging then this will diverge, so this is the main motto for this comparison test, the proof of course is

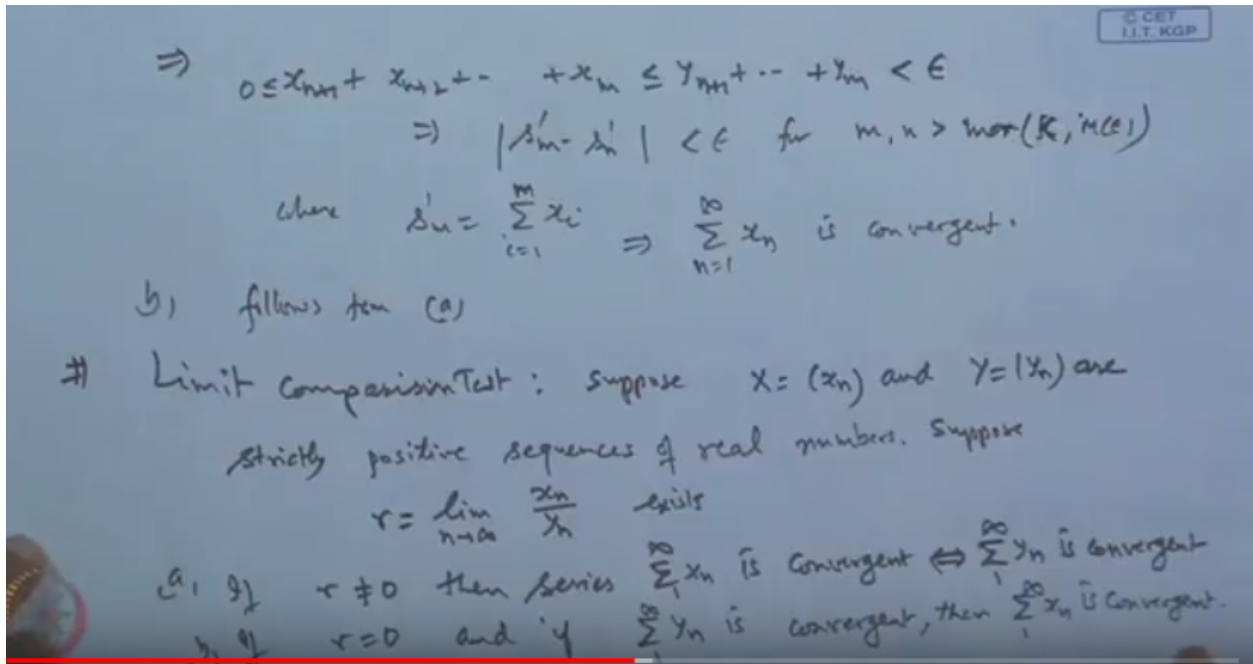

very straightforward, suppose we have this series converges given suppose, the ration hold one holds and the series, $\sum_{n=1}^{\infty} y_n$ converges, this is given, Okay? So by definition of the convergence a series is said to be convergent if and only if it is Cauchy, so for a given epsilon greater than zero, so for given epsilon greater than 0 there exists a positive integer say Capital M, which will depend on epsilon, such that for all m, n for all M which is greater than say n and greater of than equal to M of course all MN is greater than equal to M as n, I am choosing m to be larger than n, for all MN greater than equal to M,

(Refer Slide Time: (05:59))

The condition, the condition that $y_{n+1} + y_{n+2} + \dots + y_m$ is less than epsilon because basically, this condition is what? This is nothing but the $S_m - S_n$, where, S_m is the $\sum_{n=1}^m y_n$, I is 1 to M. So basically this is the Cauchy convergence criteria, so a series because it is given to be convergent so by means of Cauchy convergence criteria, for any epsilon one can identify a positive integer, so that this is a source. Okay? Now let us choose m, to be greater than the maximum value of this K, for which this result is true, this inequality is valid as well as the capital M which we have already got it because of this convergence, so if I choose m to be greater than this, then in that case the result this thing because y_n is less than equal to y_n so this part will give that $x_{n+1} + x_{n+2} + \dots + x_m$ etcetera.

(Refer Slide Time: 07:20)

This will imply that $x_{n+1}, x_{n+2},$ and so on up to say x_M , this will remain less than by $n+1$, by $n+2, y_m$ because x_n is because M is greater than the number so it satisfies both the conditions, Ok? And then this will be less than ϵ , this is true for all M greater than the maximum of K and $n(\epsilon)$ and this is greater than 0 because all terms are positive so it will be greater than or at the most equal to 0, so what this shows? This shows that this sequence s_n is a Cauchy sequence and this remains less than ϵ for all $m, n > \max(K, n(\epsilon))$, some integer, Ok? K in ϵ , and we are $s_n - s_m$ is what? As X stands for $\sum_{i=1}^n x_i$, i is 1 to M so this shows the sequence X_n is a Cauchy sequence, there it is convergent, so this implies the series $\sum_{n=1}^{\infty} x_n$ is convergent, Ok? So the proof is with, the statement follows from the first it follows from what he says the series diverges then $\sum_{n=1}^{\infty} x_n$ diverges, suppose the series given $\sum_{n=1}^{\infty} x_n$ to be a divergent series, and let this series $\sum_{n=1}^{\infty} y_n$ converges, but the statement also holds, so it means if a series y_n is convergent then according to the part a) x_n must be convergent, $\sum_{n=1}^{\infty} x_n$ must be convergent but it contradicts the result given thing because the given is $\sum_{n=1}^{\infty} x_n$ is divergent, therefore, a contradiction is because of our assumption this series converges. So wrong, so B follows from immediately, Ok?

Nothing to prove, now another test is, all let us first take the test then another test is which we call it as a limit comparison test, in fact this is the modified version of this here, because we it's very difficult to get this identity, which is valid for all N or after a certain stage, it's very, very difficult for a sequence x_n and y_n to arbitrary sequence, are there so it's not possible always to get such an inequality, therefore this test comparison may not be very much helpful, unless you know this inequality, so what is it we have slightly it is modified and a simpler form is given which is known as the limit comparison test, the test says suppose that, suppose X which is X_n and Y which is y_n are strictly positive sequences, of real numbers, of real numbers and suppose, and suppose the limit of this x_n divided by y_n over n when n tends to infinity exist. So for this limit exist say is equal to R , say is equal to R , this limit X then what it

says is if R is different from 0 means when the limit of x_n over y_n is different from 0 then the series, then the series $\sum_{n=1}^{\infty} x_n$ converges if and only if $\sum_{n=1}^{\infty} y_n$ is convergent, it means the behavior of the series $\sum_{n=1}^{\infty} y_n$ and $\sum_{n=1}^{\infty} x_n$ are parallel that if this limit x_n over y_n exists and it is different from 0 then both the series will have the same nature, if this series is convergent this has to be convergent, Okay? And second part is, if R is equal to 0 of course the divergent part here is not being some, divergence we cannot say if it is 1 is diverging other will also diverge but obviously, if we have this sort of relation that also gives a result for a divergence of the series but here we can only take the claim, about the convergent part of it, that is so far the convergence is concerned both these series will have the same nature. Same means convergent then come and if R is zero and if, and if $\sum_{n=1}^{\infty} y_n$ is convergent when is convergent then $\sum_{n=1}^{\infty} x_n$ is convergent. So there is certain limitation in this, limitation is that we are unable to test the divergence part when we cannot claim anything about a divergent, but obviously for the convergent which we are interested more to judge, the convergent with the help of the given series, Ok.

(Refer Slide Time: 13:54)

Prf. Given $\lim_{n \rightarrow \infty} \frac{x_n}{y_n} = r$

By def. $|\frac{x_n}{y_n} - r| \rightarrow 0$ as $n \rightarrow \infty$ i.e. for $\epsilon = \frac{r}{2} > 0$, there exists a positive integer K st

$$r - \frac{r}{2} \leq \frac{x_n}{y_n} \leq r + \frac{r}{2} = \frac{3r}{2} \quad \text{for } n \geq K$$

\Rightarrow $(\frac{r}{2}) y_n \leq x_n \leq (\frac{3r}{2}) y_n$ for $n \geq K$ as $y_n \geq 0$

By Comparison Test, part (a) follows

b) If $r = 0$ i.e. $\lim_{n \rightarrow \infty} \frac{x_n}{y_n} = 0$

$\Rightarrow 0 \leq \frac{x_n}{y_n} \leq \epsilon$ for $n \geq K$

$\Rightarrow 0 < x_n \leq \epsilon y_n$ so part (b) follows.

So let us see the proof of this, now what is proof is, given that, given the limit x_n over y_n , as n tends to infinity is say R , which is different from 0, of course, now once the limit is given then following any ϵ greater than 0 by definition, what happens? By definition this mod of x_n , over by n minus R this will go to 0 as n is sufficiently large, or for a ϵ greater than 0 that is for a given ϵ is forgiven ϵ say equal to $R/2$ I am taking $\epsilon/2$, greater than 0 there exist, there exist, there exists a integer, a positive integer, say K such that x_n over y_n , this will lie between what $R - \epsilon$ and $R + \epsilon$, so, here there are minus ϵ means $R/2$ and then here is also $R + \epsilon$ by 2 and

which is obviously less than $2R$, this will be less than or equal to $2R$ this hardly matters even this 3 by 2 will work. Ok? So we get the 3 by 2 so this is equal to 3 by 2 , Ok? 3 by $2R$, into now if we let like this and this is true for all N greater than equal to K , is it not? This is true for all N greater than equal to K so this happens, now from here; can we say that $R > 2$, into y_n is less than equal to the X_n which is less than equal to 3 by $2R$ into y_n , Ok? Now apply the comparison test and this is true for n greater than equal to K , because the y_n are positive, therefore when we are multiplying this it is not going to change the inequality, as y_n are greater than or equal to 0 , of course greater than 0 otherwise this will equal to 0 will help problem, so y_n is greater than 0 . Now apply the comparison say so by comparison test we can get, comparison test, this is comparison 0 and here also it so not is comparison test, Okay? So by comparison test, we can say the lizard a follows the part A follows, Okay?

That's what, now it gets second is Part B if $R > 0$ $R > 0$, means that is limit of this x_n over y_n as n tends to infinity is 0 , now since X_n and y_n both are positive non negative, so the issue a cannot be negative so clearly from here it implies that x_n over y_n will always be greater than or equal to 0 , in fact it is strictly greater than 0 because they are non-negative to on a strictly, strictly positive sequences, of real numbers instead of positive sequence of none is 0 even so x_n over y_n will be is strictly greater than 0 . Now since the limiting value is 0 it means the terms or keep on decreasing, and decreases to 0 so after a certain stage this ratio will remain less than 1 , so once it is less than 1 so you can say this is less than equal to 1 , for N greater than equal to K , this is too because limit is 0 means it keeps on in decreasing and decreases to 0 so after certain distance the ratio will remain less than or equal to 1 and it is always greater than 0 , so now what happens if we apply this if suppose $\sum y_n$ is convergent, so from here you multiply by L so this implies that, $x_n < 0$ is less than x_n less than equal to y_n , so if $\sum y_n$ convergent $\sum x_n$ will come, so Part B follows, so this is the two results.

Which will help, in getting the nature of this series whether it is convergent or not, only what we have to do we have to suitably identify Y_N Okay? And then inequality or may be the limit problem, limit third I advise that limit is a much better way of judging the, convergence of the series. So how to identify Y_M ? so that limit of x_n over y_n will exist and then nature of the y_n will decide the nature of the action.

Example 1: Test the convergence of the series $\sum_{n=1}^{\infty} \frac{1}{n^2+n}$

Sol $x_n = \frac{1}{n^2+n}$

$x_n = \frac{1}{n^2}$

Use $\sum_{n=1}^{\infty} \frac{1}{n^p}$ conv. if $p > 1$
div. if $p \leq 1$

Check $\lim_{n \rightarrow \infty} \frac{x_n}{y_n} = \lim_{n \rightarrow \infty} \frac{\frac{1}{n^2}}{\frac{1}{n^2+n}} = \lim_{n \rightarrow \infty} \frac{n^2+n}{n^2} = \lim_{n \rightarrow \infty} \frac{1+n}{1} = 1 \neq 0$

$\Rightarrow \sum_{n=1}^{\infty} \frac{1}{n^2+n}$ is conv. $\Leftrightarrow \sum_{n=1}^{\infty} \frac{1}{n^2}$ is conv. (which is true)

\therefore Ans $\sum_{n=1}^{\infty} \frac{1}{n^2+n}$ is convergent

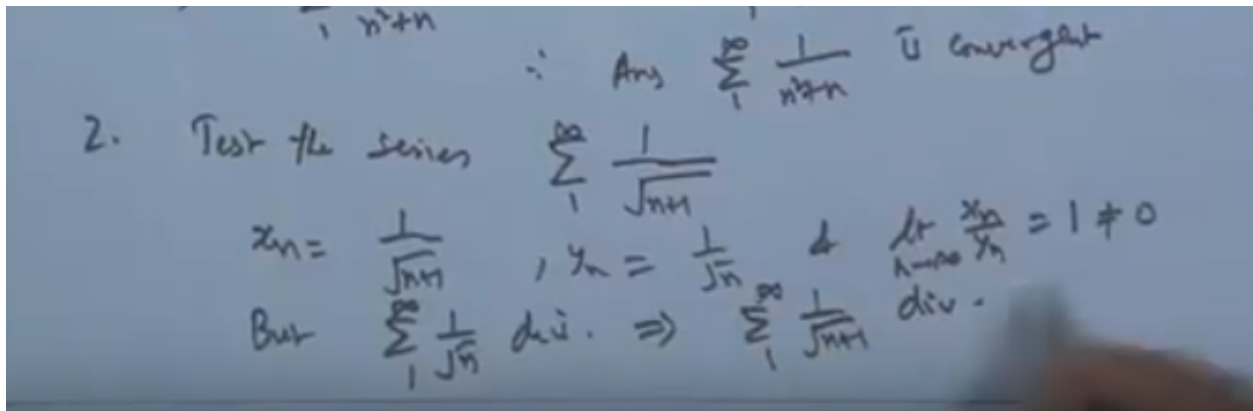

2. Test the series $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n+1}}$

Okay, let's see the few examples which you will help in getting this thing clear, suppose I wanted to test, the convergence of this series, of the series, Sigma and is 1 to infinity, 1 over N square plus n, now when we say the convergence of this at does not mean that we are only, we have to test only the convergence part convergence of the series means we have to see whether this series is a convergent series or diverges, but the way of writing is test the convergent means it includes both whether the series is convergent or divergent, Ok? So let's see this is the sequence of non-negative real numbers, strictly of course positive because n is 1 to infinity, therefore we can apply the ratio comparison limit test, but what comparison limit test says there must be the sequence x_n and y_n , this sequence if we want to test this series Sigma n you have to identify by in such a way so that the limit of this exists.

In order to identify this so here x_n is given to be 1 over N square plus n, now normally when we say the y_n to be identified, we normally use this result. Sigma we know Sigma 1 by n to the power P when n is 1 to infinity, this is Convergent, converges if P is strictly greater than 1 and diverges if P is strictly less than or equal to 1, so basically the Y N should be chosen in such a way so that it will fall in one of the in this category, so here what the trick is let us take the look, here term and anything common here outside any n square if you take outside common from the denominator take the largest power of n say outside, then what happens? If you choose by n to be 1 by n square then when you are take choosing n square outside that this becomes 1 over 1 plus 1 by n so limit of this x_n over y_n will exist. So clearly limit of x_n over y_n when n tends to infinity is nothing but what? This is equal to n square over N square plus n, limit as n tends to infinity divided by n square so 1 plus 1 by N and limit as n tends to infinity and this limit is 1 which is different from 0. So, what we see here that if you x_n and by n both are thus strictly positive real sequence of real numbers, such that limit of x_n over y_n exists, which is different from 0, therefore this series is convergent if and only if the series convergent, but this series is of the form Sigma 1 upon n to the power P where P is greater than 1, so series converges so this implies that Sigma 1 over n square plus

n is convergent, if and only if $\sum \frac{1}{n^2}$ is convergent, which is true, because of this therefore answer is the series will be convergent, so answer is the series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ plus n is convergent, is convergent, Ok? Now similarly, if you go for the another example set, let's take this example $\sum \frac{1}{\sqrt{n+1}}$, $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n+1}}$ again this is a sequence of non-negative real number strictly positive real numbers, so to test this we will apply the limit comparison test,

(Refer Slide Time: 23:59)

so let us take here to x_n here is $\frac{1}{\sqrt{n+1}}$ then by n you take if the term which is highest power here is highest power here, so highest power is 1 there are no problem and if the a when you take outside it becomes $\frac{1}{\sqrt{n}}$, so if I take this and the limit of x_n over by y_n when we choose the limit, the limit will come out to be 1 which is different from 0, you just see take root N and divide, by it means the nature of these two series are identical but the series, but the series $\sum \frac{1}{\sqrt{N}}$ $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$ this is of the form $\sum_{n=1}^{\infty} \frac{1}{n^p}$ where p is less than 1 so diverges, therefore, the series $\sum \frac{1}{\sqrt{n+1}}$ will also diverge and that's the answer,

Okay? So we can get it this way. So main idea is that, you have to pick up the suitably, the terms by n so that we can compare it with our given sequence, given series x_n the terms of the series x_n and hence, the one can identify the nature. Now this is the one which we were, very important these tests are very interesting important because it gives immediately the series nature of the series without going for this sum, because sometimes we are not interested, in getting exactly the sum of the series or the limit of the sequence of sum, because it will not help us, we are not interested in finding the sum of the series we are all interested only finding the series whether it is convergent or divergent, and for this, these tests are very much helpful.
