Lecture - 44

Lecture 44: Continuous Functions

(Cauchy's Definition)

So, we will discuss the today, the Continuity of Functions. We have already seen, how to define the functions. It is basically a mapping, a route, from a set a, to set B. Such that, each element of a, we can have one, unique element in B. Then, functions is well defined, if there are more than one values of a, then we say, it is not well-defined, of course, function. However, when corresponding to each value X, we have one value, then it is a single valued function. And for each X, if there is more than one value of the imass, more than one imas, then we says, it is a multi valued function. Say for example, FX, is the root X, there for each real x, positive real X, we have two values. So it is a multi valued functions. So we will include, all sorts of the functions, whether it is a single valued function or multi valued function. And when we say, FX is a real valued function, it means, that values of the FX, lies in the real M.

(Refer Slide Time: 00:39)

So let F_X , be a real valued function, that by the domain of F, we mean, domain of F, we mean, the set of those real numbers, are, set of those real number X belongs to \mathbb{R} , such that, the F_X is well defined, well defined, at this. Means F_X , should not be infinity or minus infinity or the functional at X and it must be, a finite value, well defined. Normally the domain of F, in general, the domain of F, normally we consider, either a open interval or may be a closed interval or may be a semi closed interval, say like this or even the entire real \mathbb{R} . So it depends on the function, where it is defined, we are not. And the set of those values, of F, is the range of F, range of F, means, those y's, such that, there exists some X, such that F_X equal to Y, for X belongs to the domain of F, okay. So all the imas is set, is the range of the F, so this much we have. Now the domain of F or the function, when we say the function is defined over a dominant F, then it is not necessary, that function, the domain will be a

continuously defined like, a b. It may be, in the break up form, may be the function may not be defined, same function may not behave, may not be defined, over the entire domain, it may be, if several functions, can be take up, over the domain of the F. For example, if we say FX is say 0, when x is 0, say FX, is equal to, lying between, say 1 by, n plus 1, less than X, less than equal to 1 by n, where n is, an integer ,greater than equal to 2 say, then the value of this is defined as the one functional, FX is defined by 1 by n, so in the interval when it is lying between, 1 into, 1 ½, less than X, less than equal to 1, the function is defined suppose 1. So this is, also a way of defining, the function, means a function, may be take up of this type of also, where the interval, the domain of definition, is from 0 to 1. But it is not the same function, by means of the same function; we are not defining over the interval. What we are doing, what we have here is, over these several parts of this interval 0 1, this is 0 1 interval, we have a different form of the F, at different points, all even if different subintervals like this, so this means. Now there are different types of the functions, which we come across, the like the rational, types of real valued function or types of functions, which we will come across. The first, may be, a rational integral function, a rational integral function, all polynomial, we can also say it is a or a polynomial, which is of the form, like, a naught, plus a 1 X, a 2, X square, plus a n, X to the power n, well the coefficients, a naught 8, a naught, a 1, a 2, a n, these are all constants, real constants. Okay? And N is a positive integer, positive integer, belongs to n. So this is also a functional and we denote by PN X, a polynomial, of degree n.

(Refer Slide Time: 05:50)

(i) Rational function

$$f(x) = \frac{P(x)}{Q(x)}, \quad P(x) \neq 0 \quad \forall x \in D(f)$$

(ii) Algebraic function is a function which can be expressed as the root an equation of the form

$$y^n + F_1 y^{n-1} + \dots + F_n = 0$$
 where F_1, F_2, \dots, F_n are rational functions of x

(iv) Transcendental function is that which is not algebraic functions
 logarithm, Trig; exp...

another type of the function, which we come across, about the rational functions, rational functions. A function $f(x)$, which is of the form, which is of the form, $\frac{P(x)}{Q(x)}$, where $P(x)$ is also a polynomial, say of degree n , $Q(x)$ is a polynomial of degree say, N . But $Q(x) \neq 0$. For any x , belongs to the domain of f , for every, for every x , belongs to D , $f(x) \neq 0$. Then such a function, we call it as a, rational function. And then, a third type of the function, which we can approach, as algebraic function. Algebraic function, is a function, is a function, which is or which can, be which can be, expressed as, as, as the root of, root of, an equation, of the form, say, $Y^n + f_1 Y^{n-1} + f_2 Y^{n-2} + \dots + f_n = 0$. Where, this f_1, f_2, \dots, f_n , these are rational functions of X . Where these, f_1, f_2, \dots, f_n , are rational functions, functions, of X . So the roots of this equation will be a function. Because these are all rational functions, coefficients are rational function, so the roots will be a function and that. Function we call it as a algebraic functions. Then transcendental functions, transcendental function, are those functions, which are not algebraic. Is the, is that function, which is not algebraic function, which is not algebraic function. So, transcendental functions are that. Now in this case, we have seen so many examples, like logarithmic functions, logarithmic function, and then trigonometry functions, like trigonometry functions and then exponential functions, all these, new function, will come across, for this. So we will discuss in general first, the continuity of these type functions. And then we will see that this functions which are smooth continuous and also the some uniform continuity, will also test it will be more useful to develop further the x . Okay, so let's come to now before going for this application say definition for continuity we will also look we require the bounds for it.

(Refer Slide Time: 09:37)

Bounds of functions

Let $y = f(x)$ be a real valued function defd over its domain of def.

If set of the values of y corresponding to the different values of x , $x \in D(f)$, is bounded Then we say $f(x)$ is a bounded function i.e. $\exists M > 0$ s.t.

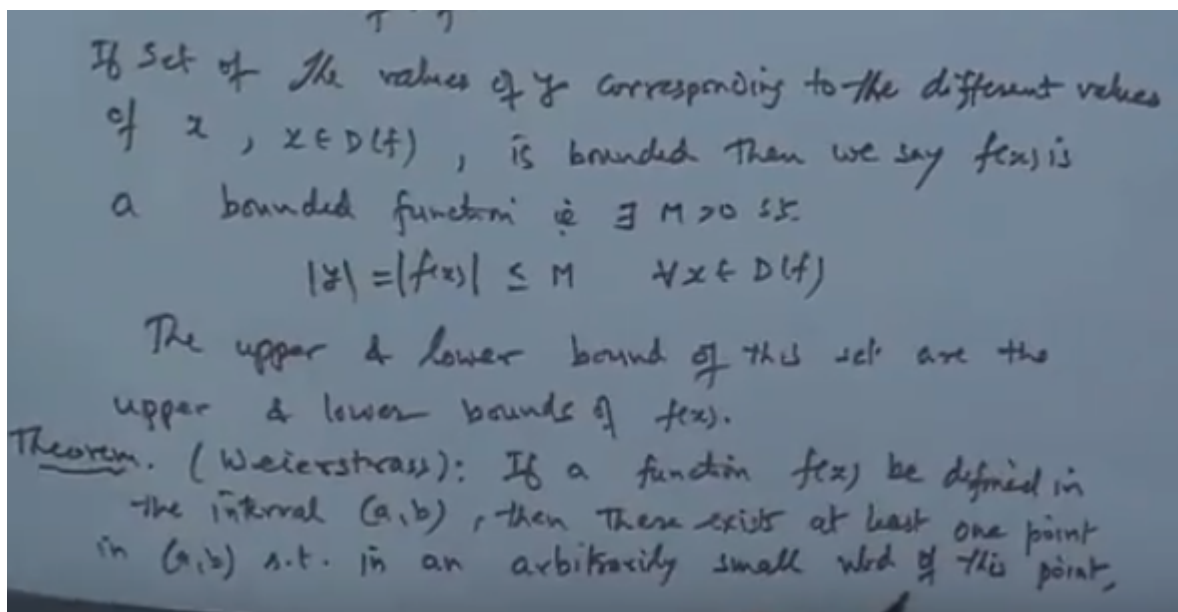

$$|y| = |f(x)| \leq M \quad \forall x \in D(f)$$

The upper & lower bound of this set are the upper & lower bounds of $f(x)$.

Theorem. (Weierstrass)

so let Y or the bounds bound of the functions the bounds of functions in fact this is when we say the function $f(x)$ is bounded when we do we say so let F by is equal to $f(x)$ be a real valued function define over its domain its domain of definition whatever whether it interval or maybe a union of the disjoint intervals and like this interval the set the values of y by the values of y corresponding to corresponding to the different values of x x so this will form a set the values of y corresponding to the different values of x so if the set of set of the values of Y corresponding to different values of x if it is bounded if the set of values of Y corresponding to different values of x where the x belongs to the domain of F is bounded then we say the function $f(x)$ is a bounded function, it means that is mod of $f(x)$ is less than equal to some constant that is there exist some M greater than zero such that this is true for all x belongs to the domain of F . What is $f(x)$? $f(x)$ is by basically the value of F at the point x do trade able by so if the set of all set of values of $f(x)$ if this set is a bounded set then we say the function f is a bounded function and in the similar way the upper and lower bound of this set the upper and lower bound of this set upper and lower bound of this sets are the upper and lower bound upper and lower bound bounds of the function $f(x)$ that is 1 the upper bound of $f(x)$ then find out the or M and then among these M find the upper bound so that upper bound will be the upper bound for $f(x)$ similarly the lower bound for $f(x)$ like this if this upper bound is finite fine otherwise a this may be unbounded set if that upper bound we are not able to get M to be finite okay.

(Refer Slide Time: 13:02)

So one more results which we require here that is a theorem given by Weierstrass theorem of says if a function $f(x)$, we defined in the interval a B of interval a B , then there exists, then there exists, at least there exists at least one point, at least one point, in the interval a B in the interval a B , such that, says that in an arbitrary small in an arbitrarily small neighbourhood of this point, of this point, of this point, at this point

(Refer Slide Time: 14:36)

the l.u.b. of $f(x)$ is the same as in (a, b)

Pf. let $M = \text{l.u.b. of } f(x)$
 $a < x < b$

Divide (a, b) into 2 equal intervals of length $= \frac{b-a}{2}$

each

Call it this interval (a_1, b_1) in which $f(x)$ has an u.b.

Again, divide (a_1, b_1) into 2 equal intervals of length $= \frac{b-a}{2^2}$

Pick the interval (a_2, b_2) in which the $f(x)$ has an u.b.

Continue. then

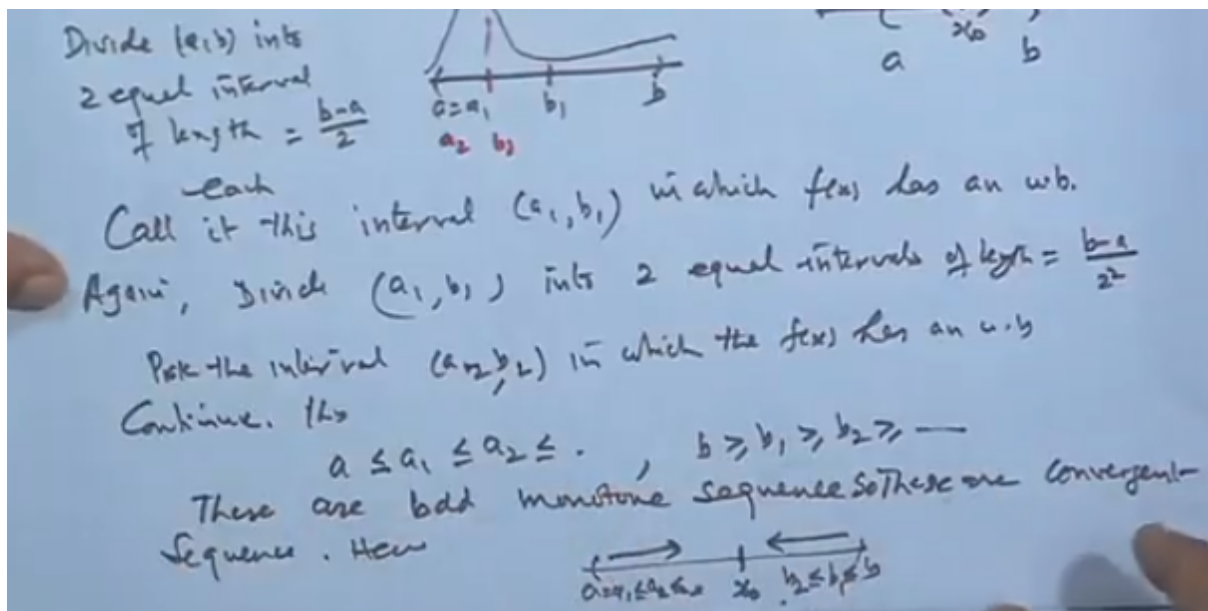

$$a \leq a_1 \leq a_2 \leq \dots, \quad b \geq b_1 \geq b_2 \geq \dots$$

These are the intervals mentioned in the proof.

the least upper bound of $f(x)$, the least upper bound, of $f(x)$, this double bound of $f(x)$, is the same as as in a, b , so what it says is if suppose the function we define this is a function suppose this is interval and the function is defined everywhere at this everywhere it is the function is well defined then it just a point say x_0 in the interval a, b such that in an very small neighbourhood, if I choose then this function will have the same upper bound as it is in over the entire thing. Say if I choose this function suppose this is only function suppose I take this function this function suppose I did. Okay? Now you see the upper bound maximum value is attained at this point. Okay? Now we can find it very small a point x_0 so that in an arbitrary small neighbourhood the upper bound of the function $f(x)$ is the same as the upper bound of the function over the entire range a, b that's what is the short set the proof is obviously the function is, throughout well-defined function the proof is very simple. Suppose the upper bound of this is, suppose M . Okay? Then what we do? Let us find that, by section of this interval, such that, we get this, let M be the upper bound of this okay so let M be the upper bound of $f(x)$ over the interval X , belongs to a, b . Okay? x_0 belongs to a, b , this is an upper bound, for this, say least upper bound, we can say is this if it is close interval then we can say say least upper bound of this on the close interval let it be it's okay no problem okay now this interval is given we divide this interval into two parts of equal length now we pick up that interval in which that least upper bound occurs okay suppose we

have this say this curve suppose like this suppose this curve is so what we do if we divide this in a to equal intervals and then we pick up the interval $a_1 b_1$ which is divided a B interval into two equal intervals of length B minus a by 2 each of length this each each of this length so let pick call that interval pick up that interval in which the least upper bound is there so obviously here $a_1 b_1$ in this interval this upper bound lies okay so this even women call it this call it this interval $a_1 b_1$ in which the function $f(x)$ has an upper bound, a perfect college this now this a_1 may consult with a or demon may coincide with B depending on the function now further again divide $a_1 b_1$ interval into two equal intervals of length equal to B minus a_1 by 2 square and then pick up this called that interval pick up the pick up the interval say $a_2 b_2$ in which the function $f(x)$ has an upper bound so you are further dividing this into your further dividing it into two so now I am picking up this this is we call it a_2 this is B_2 because in this only the upper bound lies continue this process so if I continue this process what happens we are getting in this process when you continue you are getting the sequence of the points $a_1 a_2 a_3$ hence such that $a_1 \leq a_2 \leq a_3$ and so on well B is greater than equal to B_1 greater than equal to B_2 and so on so asnt increasing Simonton increasing sequence B is a monotonic decreasing sequence but the upper bound of a cannot exceed by Bhiemma and lower bound of this when you take the B_1, B_2, B_N all these things the lower bound of this will be again when you take B, B_1, B_2, B_1 is an upper bound here is it not so this is bounded above this bounded below and below will be at the most B it B okay so this will be the both are so.

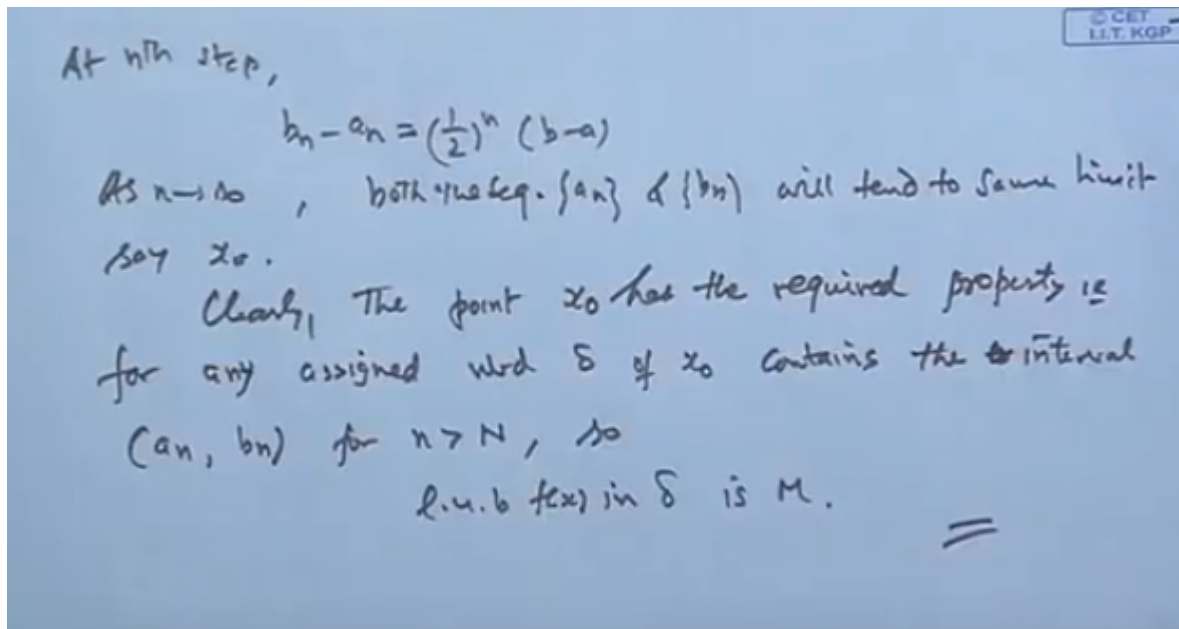

(Refer Slide Time: 20:39)

these are the monotonic sequence these are bounded monotonic, monotone sequences and we know the bounded monotone sequence of real numbers or rational numbers they are all convergent so they will converge so they converges so they are these are convergent sequence so these are convergent sequences hence n will converge to a point B n will converge from

there so we get from here a B so a a 1 less than equal to a 2 less than equal to a 3 n be greater than B 1 greater than B 2 and so on so a n will go this side B n go to this type so a point X naught can be friend we have the limit of this will coincide ok.

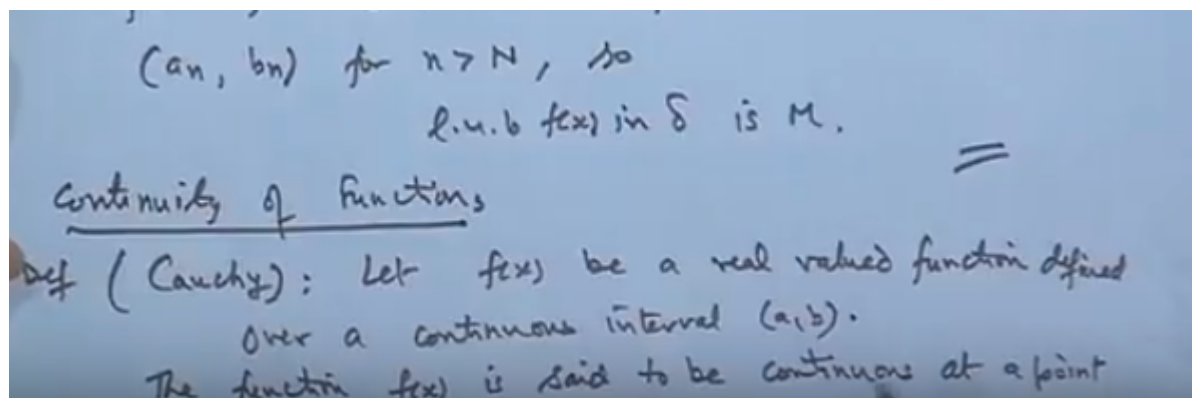

(Refer Slide Time: 21:43)

Why because at the N th step what we get the difference between B and a_n will be $1/2$ to the power n $B - a_n$ so as n tends to infinity this difference is very very small therefore as n tends to infinity both the sequence a_n and B_n will tend to the same limit same limit and that limit point is about a say x_0 it means there exist an x_0 and a neighborhood around the point x_0 will be there in vista upper bound right ok so the point x_0 the point clearly the point x_0 has the required property required property, property that is for any sign for any sign for any sign neighbourhood Δ of x_0 Δ of x_0 contains the interval in comma B for large n so that so the least upper bound of the function $f(x)$ in Δ each that's what it okay so this basically is proved and assuming the function is well defined at each point of this so the continuity is obviously is taken in consideration here so not looking of there now we come from for Murray the definition of continuity so there are two ways of defining the continuity one is given by the Cauchy another one is given by Henning. So Cauchy has taken in the form using the epsilon-delta definition that in terms of the intervals well that Henning is defined the continuity of the function in terms of the limit of the sequences but both these concepts both the definition are basically equivalent definition.

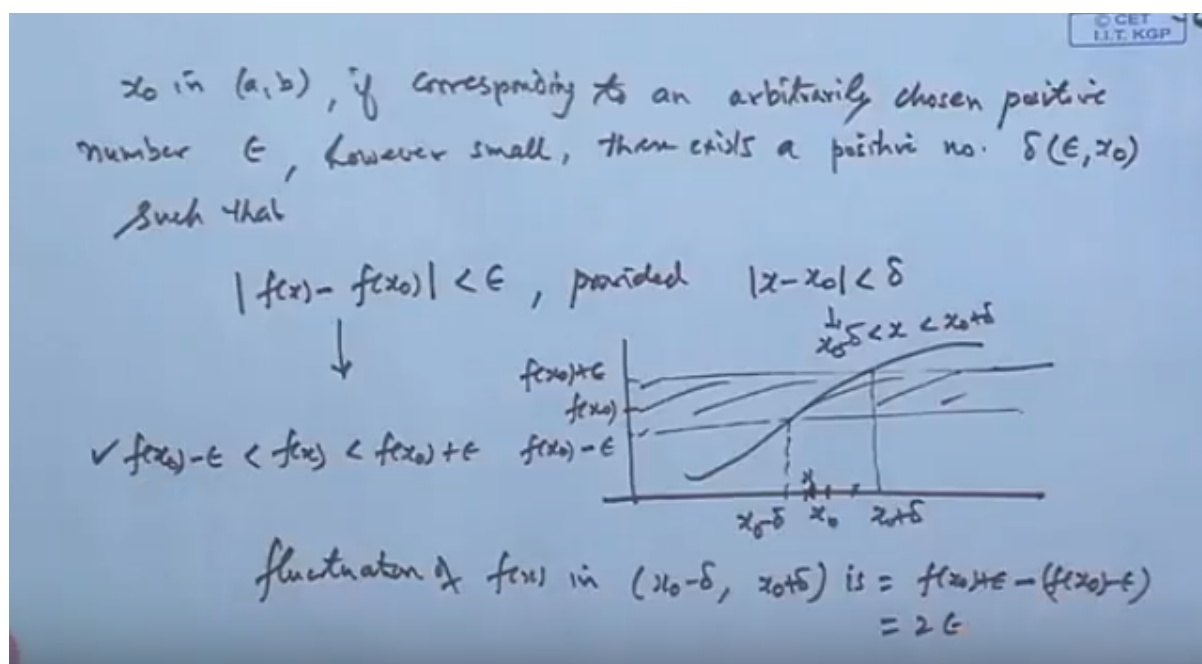

So we will say first what are these definitions and then we will justify that these two definitions are basically an equivalent definition.

(Refer Slide Time: 24:34)

So let's see the continuity of the function of functions so first the definition by Kochi coach its definition what the course is efficient let the dominoes continue let $f(x)$ be a function we have real value function define defined over a continuous interval a B of course here we are taking a continuous interval or but it may be the partly function will also be defined within a different way so over a continuous function interval a B and let by equal to $f(x)$ be the given values of the function at this interval then the function $f(x)$ the function $f(x)$ is said to be continuous is said to be continuous at a point at a point x naught,

(Refer Slide Time: 26:06)

in the interval a, B , if for a given ϵ greater than zero or if corresponding to an arbitrary
 if corresponding to an arbitrary corresponding to an arbitrarily choosing arbitrarily chosen
 positive number ϵ positive number ϵ how small may be however is small her very
 small another there exist corresponding to this there exist a positive number Δ which
 depends on ϵ as well as on the point X_0 such that such that the modulus of $f(x)$
 minus $f(x_0)$ is less than ϵ provided $|x - x_0|$ is less
 than Δ it means what the meaning is this a function f is continuous at a point X_0 if
 for a corresponding to a sine arbitrary choosing positive number ϵ there exist or Δ there exist a Δ depends on
 ϵ depends on ϵ so such that this condition hold it means that if we take ϵ is
 given then we can find out a neighbourhood of X_0 not say $X_0 - \Delta$ and $X_0 + \Delta$ a neighbourhood can be obtained with respect to this given ϵ with respect to
 the bond which is given here such that the $f(x)$ of any point x will always fall within this
 range will always fall within the same that is here is say $f(x_0)$ then the range fluctuation
 of this will be $f(x_0) - \epsilon$ $f(x_0) + \epsilon$ of $f(x)$ minus $f(x_0)$ less
 than ϵ this implies the $f(x)$ lies between $f(x_0) - \epsilon$ and $f(x_0) + \epsilon$
 and this we mean that x lies between $X_0 - \Delta$ and $X_0 + \Delta$ it means
 so if f is continuous then a neighbourhood of the X_0 exists such that $f(x)$ of any point
 x in this neighbourhood will always satisfy this condition that it will always fall within this
 to ϵ signer bits of that step whatever the point is choose if so then we say it is reference it
 means the total fluctuation the fluctuation of the function of the function $f(x)$ in the interval $X_0 - \Delta$ to $X_0 + \Delta$ what the is basically the difference between
 these two upper and the lower bound so $X_0 + \epsilon$ minus $f(x_0) - \epsilon$ and
 that is equal to 2ϵ so if this fluctuation is less than.
