

Module – 8
Lecture 45: Continuous Functions
(Heine's Definition)

So, in the previous lecture, we have introduced, various types of functions, of real variables and an important result. Namely the Weierstrass theorem, on the bond, of the functions effects, in continuation, we have also discussed the cauchy definition of continuity, of the functions. In this lecture, we will introduce the hennas definitions of continuity, of the

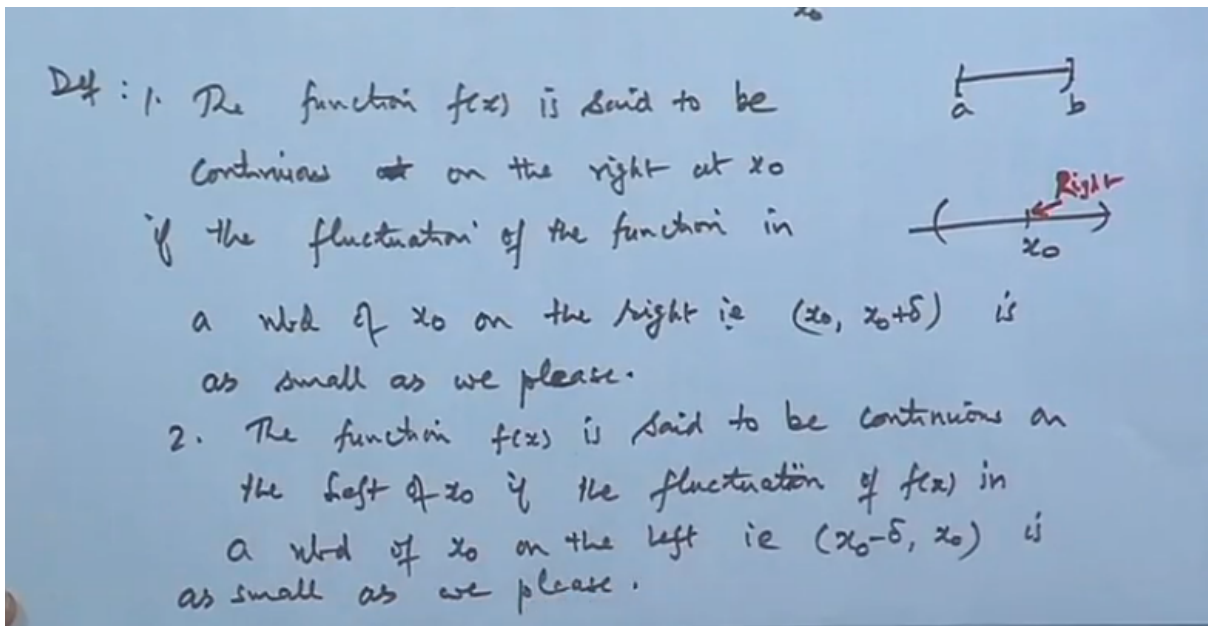

function and then, we will establish the equalization, between these two definition of continuity. you can say important note.

Refer Time Slide 0:52

We can say the function $f(x)$, the function $f(x)$, is continuous at a point, at the point, function $f(x)$, is continuous at a point, if a neighbourhood, if a neighbourhood, if a neighbourhood, of the point, never of the point, the neighbourhood of the point, can be determined, can be determined, in which, in which, the fluctuation, the fluctuation, is as small, as we preach, is it more HB please as we please so this is consequence this is considered in the necessary condition because if this does not satisfy the function cannot be continuous function.

(Refer Time Slide Time: 2:19)

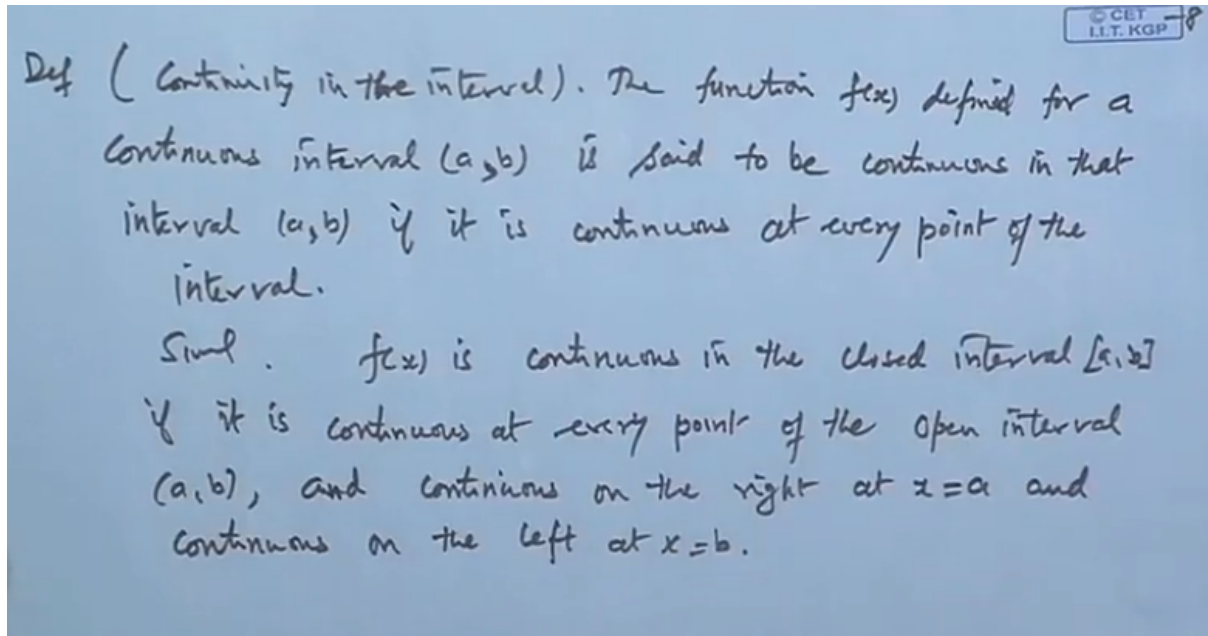

For example suppose I take this graph say this is our graph point X_0 is here function f is this now how Sabre is more with this given F sign say with this given F epsilon I take this point is say $F X_0$ so this point is $f X_0 - \text{Epsilon}$ this point will be $F X_0 + \text{epsilon}$ and here this is $f X_0$ so for this f epsilon this is the Wits to epsilon for a given epsilon if we get there must exist an interval neighbourhood around the point X_0 such that the friction should not exceed by Epsilon but what happen if it suppose I take this neighbourhood okay this is our neighbourhood like this so as soon as you take this point say here this is point here as soon as this point the corresponding image of this will go here it means the fluctuation may exceed by 2 Epsilon so it cannot be made as small as we please and this is because there is no continuity of the curve at this point X_0 so such a function will not be considered as a continuous function so that's the important that's why we say this is a case of discontinuity, continuous function case of discontinuity.

Okay? Because of this thing, clear so that's why, it is necessary good now, as a corollary of this, of course, the fruit we further extend this. Suppose a function is given over a closed interval the domain of definition is closed interval and when we say the function is continuous over the closed interval then what we do, we take the open interval first and then at the point a and B , also be test it. But before if the function, may not be defined after B the function main also not be defined so we have to modify our definition of the continuity at the endpoint of the interval, so we say the function is said to be the function the function is said to be $F X$ is said to be continuous, at continuous, on the right, on the right at X naught, So for this is X_0 on the right means this side this side okay on from the right hand side this is right on the right of X_0 right on the right at X_0 , it X not on a function set we continue that if the fluctuation of the function if the physician, of the function, in a neighbourhood of X_0 if the fluctuation of the function in a neighbourhood of X_0 , on the right, on the right, that is, that is $(X_0, X_0 + \delta)$ this is, the neighbourhood on the right of this if the fluctuation of the function in the neighbourhood of X_0 , on the right of X_0 on the right each edge small as we please then we say the function is continuous at a point X_0 , from the right hand side. Similarly the function is said to be continuous on the left the function $F X$ is said to be

continuous on the left, left, of X_0 , if the fluctuation is the fluctuation of the function in a Neighbourhood in a neighbourhood of X_0 , on the left on the left means that is $(X_0 - \delta, X_0)$ on the left is Edge moor, as we please so that's the important one okay so now we can define the a function over the continuity in the interval.

Refer Time Slide: 7:53

So, we define as a continuity of the function, continuity in the interval, the function $f(x)$, function $f(x)$, defined for a continuous interval defined for or continuous interval a B continuous interval a B is said to be is said to be continuous is said to be continuous in the interval a B in that interval a B that is at each point if it is continuous if it is continuous if it is continuous at every point at every point of the interval okay if it is a closed similarly we say $f(x)$ is continuous $f(x)$ is continuous in the closed interval or over the closed interval a B over the closed interval a B if it is if it is continuous at every point at every point of the open interval of the open interval a B of the open interval a B and continuous on in continuous and continuous on the right at X equal to a and continuous and continuous on the left at X equal to B .

(Refer Time Slide: 10:57)

Stmt. $f(x)$ is continuous in the closed interval $[a, b]$
 if it is continuous at every point of the open interval
 (a, b) , and continuous on the right at $x=a$ and
 continuous on the left at $x=b$.
 Ex Prove that $f(x) = \sin x$ is continuous $(0, \frac{\pi}{2})$
 In fact it is continuous over \mathbb{R} .
 Sol $\epsilon > 0$ given

We say the function is continuous okay now let us take an example which is using the
 epsilon- δ definition suppose put that $f(x)$ equal to sine x is continuous function it's continuous
 say over the interval 0 to π by 2 in fact it is continuous everywhere because it is a periodic
 function so we can say it ok say 0 to π by 2 it's continuous in fact it is continuous over the
 entire real line are over the entire deal I not so the proof is simple suppose epsilon is given
 greater than zero is given okay we have to find δ depends on epsilon so that the mode of $f(x)$
 $- f(x_0)$ less than epsilon is less than epsilon provided $x - x_0$ not less than δ so consider this

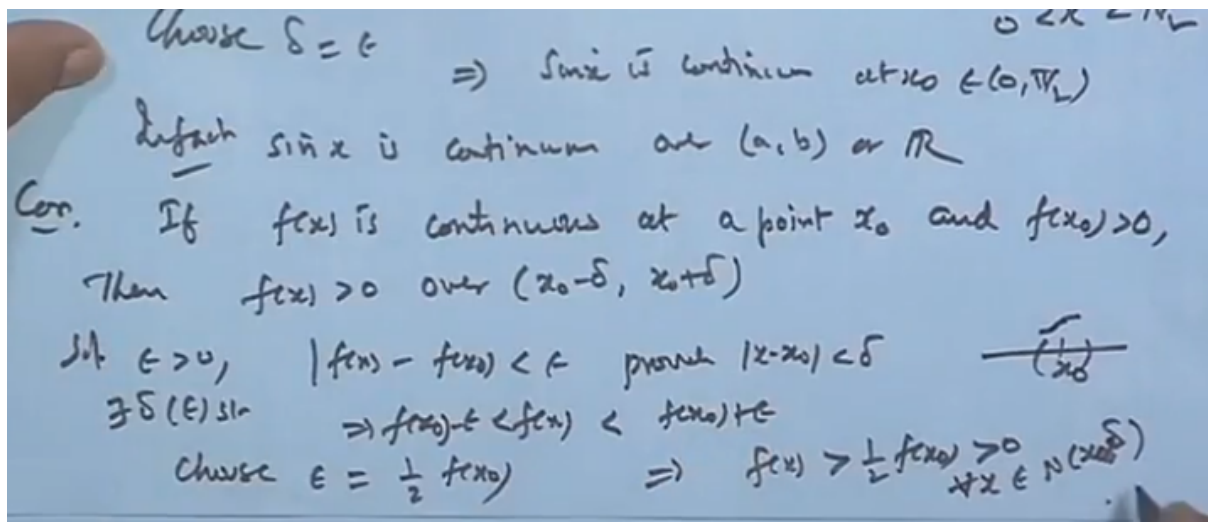

(Refer Time Slide: 11:58)

Consider Let $x_0 \in (0, \frac{\pi}{2})$
 $|f(x) - f(x_0)| = |\sin x - \sin x_0|$
 $= |2 \sin(\frac{x+x_0}{2}) \sin(\frac{x-x_0}{2})|$
 $\leq |x-x_0| \quad \because \sin z \leq z \quad 0 < z < \frac{\pi}{2}$
 Choose $\delta = \epsilon \Rightarrow \sin x$ is continuous at $x_0 \in (0, \frac{\pi}{2})$
 In fact $\sin x$ is continuous over (a, b) or \mathbb{R}
 Cor. If $f(x)$ is continuous at a point x_0 and $f(x_0) > 0$,
 then $f(x) > 0$ over $(x_0 - \delta, x_0 + \delta)$

consider mode of $f(x) - f(x_0)$ we are let x not be a point in this interval suppose okay or not
 then what is this this is sine $x - \sin x_0$ not but this is equal to 2 times sine $\frac{x+x_0}{2} \sin \frac{x-x_0}{2}$ by 2 into
 sine $\frac{x-x_0}{2}$ by 2 mode of this which is less than equal to now sine of this thing is a bounded

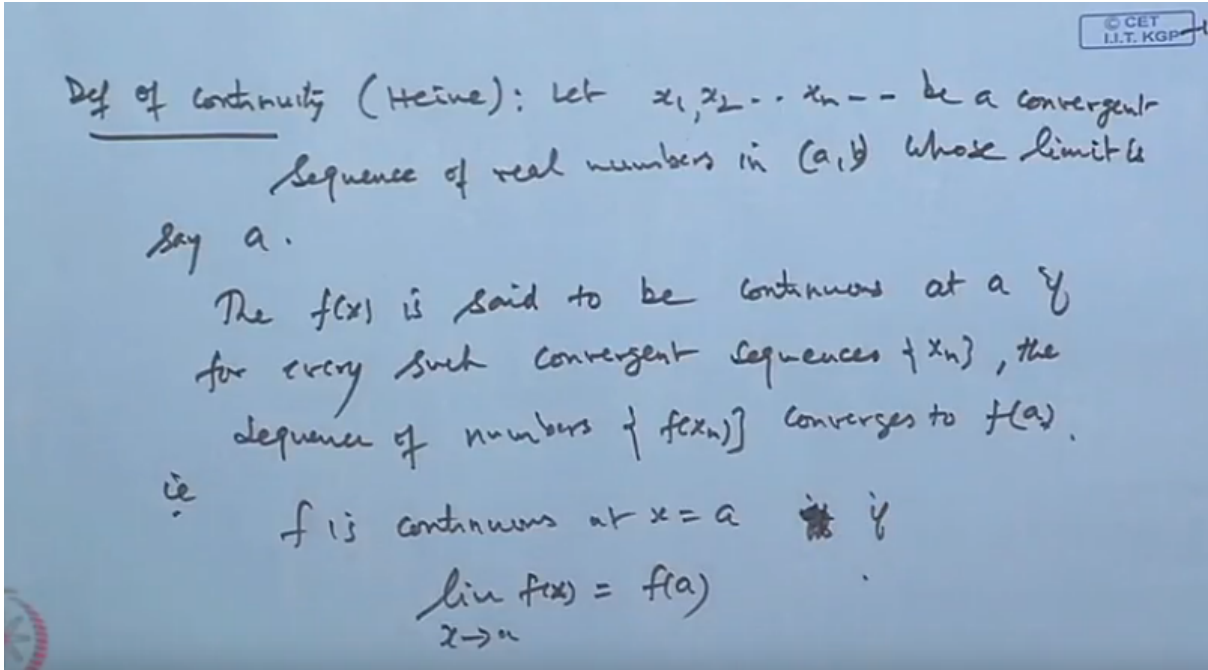

function bounded by 1 so this is less than equal to 1 and this sign will be less than equal to $|x - x_0|$ why because mode of sine because the sine x is less than equal to x for x lying between 0 and π by 2 sine 0 is your sine 90 is π by 2 or even 0 to π it will help ok so any interval you can just say this is in fact this can be extended for any $x \in \mathbb{R}$ ok so this is 2 now if I take the δ so it shows δ equal to Epsilon so if this is less than δ obviously this will less than Epsilon so this source the sine x is continuous at x_0 but x_0 is an arbitrary so it is continuous everywhere and even if we stake interval sine x is basically is continuous over any close any open interval a, b or in the \mathbb{R} line in fact this one can prove easily so this is one of the example which we have I have chuji now currently there is one small result which we call the Connery if $f(x)$ is continuous if $f(x)$ is continuous at a point x_0 and $f(x_0)$ is positive then then $f(x)$ is positive over the entire interval $x_0 - \delta$ to $x_0 + \delta$ means if the function is continuous at point.

(Refer Time Silde: 14:22)

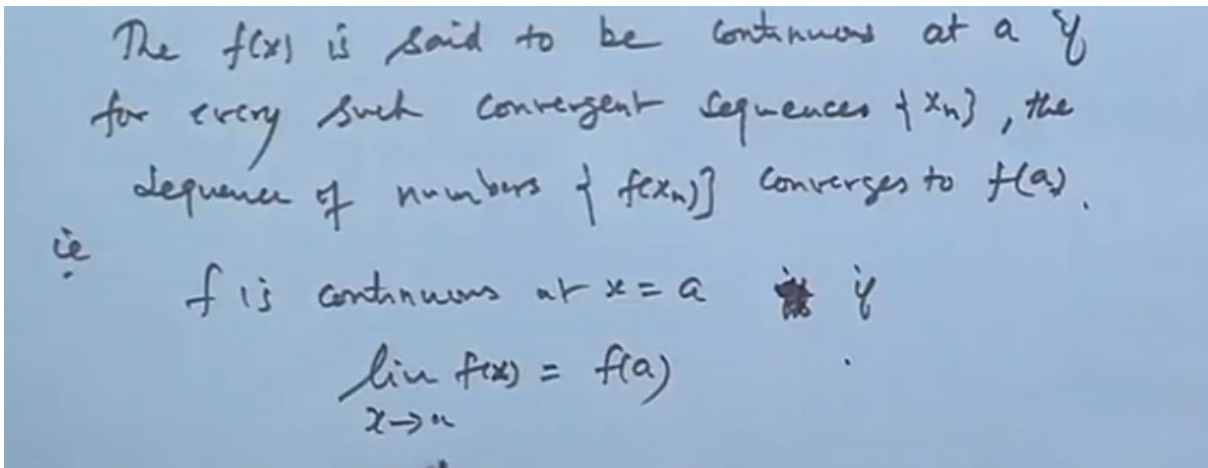

At the point x_0 it is positive function it is a positive function graph is up then we can find a neighbourhood where the function will remain positive okay the reason is because it is continuous so this condition is satisfied for a given epsilon greater than 0 there exists a δ depending on epsilon such that this is to provide it mode of $|x - x_0|$ less than δ so when the x lies between this then what happen this so the $f(x)$ is lying between $f(x_0) + \epsilon$ greater than $f(x_0) - \epsilon$ so if I choose a channel to be half of $f(x_0)$ then obviously $f(x)$ will always be greater than the will be basically half of $f(x_0)$ because of the left hand side which is positive so this is true for all x belongs to the internet would and neighbourhood of x_0 neighbourhood of x_0 with a radius δ .

(Refer Time Slide: 15:42)

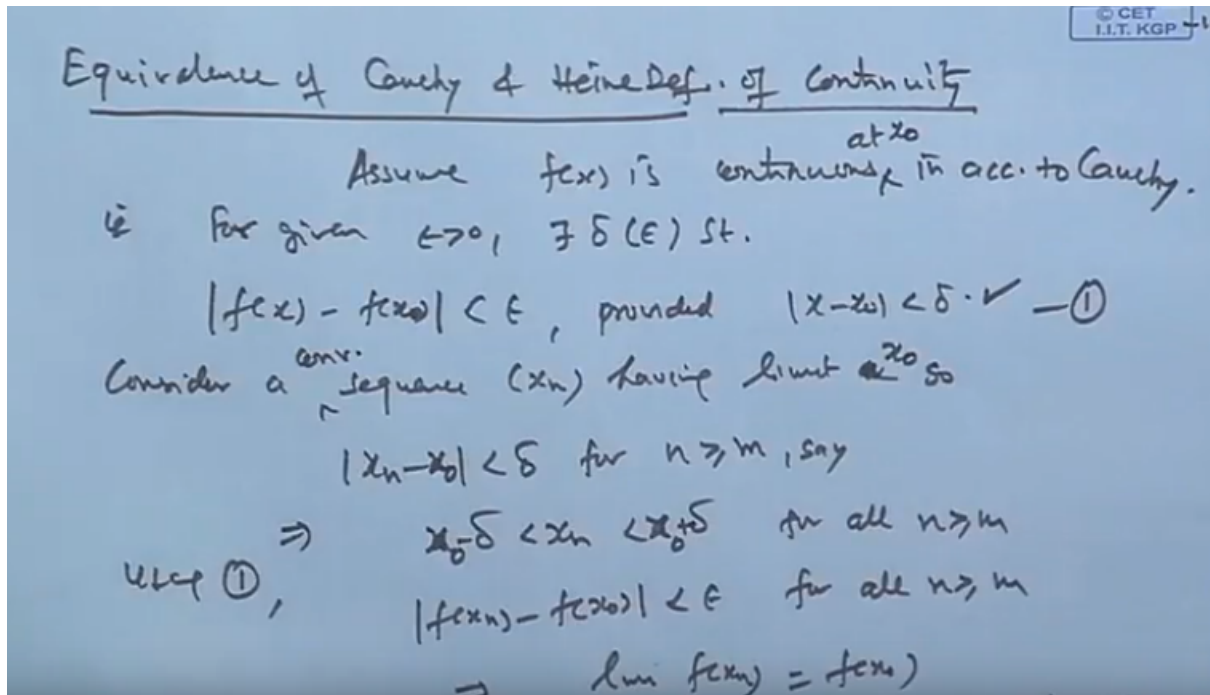

Okay so this disc now Honeywell definition foreign definition of continuity given by Hanny this is given in terms of the sequence so what he said let $x_1, x_2, x_n, x_1, x_2, x_n, \dots$ a convergent sequence convergent sequence of real number set of real numbers all points on the real line in the given interval a, b in the given interval whose limit is limit is say a limited say a the function $f(x)$ by definition of the function $f(x)$ is said to be continuous is said to be continuous at a point a if for every such sequence for every such convergent sequences sequences x_n every such convergent sequence x_n the sequence of their functional value sequence of numbers functional means it is numbers now f of x_n the serial numbers converges to f of a that is the meaning is f is continuous at a point x equal to say x equal to a if the limit of the function $f(x)$ when x tends to a exists and coincide with the functional value at this definition is if and only if in fact this is the definition given by this is okay if this condition okay in fact is part if and only if so constantly.

(Refer Time Slide: 18:03)

So what he says is that if we take a sequence action which converges to a then f of x_n , will go to F , the definition given by the Eny, now these two definitions are basically equivalent definition the equivalence of Cauchy's and Eny's definition of continuity so let us assume the function is continuous assume.

Refer Time Slide: 18:17

$f(x)$ is continuous, continuous, in accordance, in according to Cauchy, Cauchy's, it means that is or a given epsilon greater than 0 there exists a δ depending on epsilon such that mode of $f(x) - f(x_0)$ not continuous at x_0 $f(x_0)$ is less than ϵ provided mode of $x - x_0$ less than δ suppose this is true okay now let us consider a sequence x_n a convergent sequence a convergent sequence x_n having the limit a means excellence you can converge this to a so by definition so by definition so modeulus of $x_n - a$ less than said δ for all N greater than equal to say capital is small M say because limit of x_n is a so $x_n - a$ will remain less than after a certain stage but if x_n lightness this implies that x_n lies between $a - \delta$ $a + \delta$ for all N greater than equal to n and for such point which lies in this one satisfy this condition so using one what we get is mode of $f(x_n) - f(x_0)$ yes continuous at x_0 so here x_0 actually I have taken a limit is x_0 let us take x_0 here so x_0 so here is x_0 this is also x_0 because in place of this so $f(x_0)$ this will remain less than epsilon for all N greater than equal to therefore limit of $f(x_n)$, as n tends to infinity is $f(x_0)$ hence Eny's definition follows hence by Eny's definition f is continuous at conversely, conversely, suppose Eny definition.

Refer Time Slide: 21:17

Constr: Suppose f is continuous at x_0 in accordance to Heine def
 But Cauchy def is not satisfied i.e. for given $\epsilon > 0$, there
 exists points in $(x_0 - \delta, x_0 + \delta)$ for which
 $|f(x) - f(x_0)| \geq \epsilon$, however δ may be ^{small} $\text{---} \textcircled{2}$

Consider a sequence $\{\delta_n\} \downarrow \text{---}$ and $x_n \in (x_0 - \delta_n, x_0 + \delta_n)$

$$\textcircled{2} \Rightarrow |f(x_n) - f(x_0)| \geq \epsilon$$

$$\Rightarrow \lim_{n \rightarrow \infty} f(x_n) \neq f(x_0)$$

~~$\lim_{n \rightarrow \infty} f(x_n) = f(x_0)$~~
 f is not cont at x_0

Suppose f is continuous at x_0 in accordance to Heine's definition and its definition so for this suppose we say it's continuous in accordance well but, but Cauchy definition is not, Cauchy's definition is not, is not satisfied. That is for a given epsilon greater than 0 for a given epsilon greater than 0 there exist points there exist points in the interval in the interval say $x_0 - \delta, x_0 + \delta$, for which, the fluctuation mode of $f(x) - f(x_0)$ exceed by any number ϵ epsilon house ever is more δ maybe, δ may be. So what do you mean by this? This means, if you take a sequence which is in this okay then all this you can so let us take a consider, consider, a sequence a sequence δ_n of decreasing nature which decreases to zero, converges to 0, such that secant δ_n will converges to 0, and it says that and x_n be a point belongs to this $x_0 - \delta_n, x_0 + \delta_n$ if we take this point in this sequence of the point in this interval then in then according to the second implies that mode of $f(x_n) - f(x_0)$ will greater than, equal to ϵ epsilon. This shows the limit of the $f(x_n)$, as n tends to infinity, as sorry, as x tends to x_0 , that is n tends to infinity, mean x_n , n tends to infinity, is not equal to $f(x_0)$. So function f is not continuous at x_0 all this contradicts the definition of this therefore this assumption that Cauchy definition is not very, satisfied is wrong here for this. Okay, thank you very much. So this was the equivalence of this.
