

Okay so this is the next lecture... in fact tutorial lecture say 10. We will discuss few problems on, based on the mean value theorems. So first problem is a function... a function F is thrice, differentiable... differentiable on a closed interval say $A B$... on a closed interval $A B$ and F of A is 0 , F of B is also 0 and suppose this... let the function F prime A is also 0 , let us suppose F prime A is also 0 , F prime B is also 0 , then prove that... prove that F is thrice differential function on $A B$, we can also say such that this and this happens... this and this happens, okay that is better. A function F is thrice differentiable on $A B$, such that F of A is 0 , F of B is 0 , F prime A is 0 , F prime B is 0 , then prove that there exists a C , in the interval $A B$ such that this third derivative of the function at the point C is 0 , okay. So what is given is the interval $A B$ is given. the function F is thrice differentiable, so it is continuous function differentiable, and at the point A the function is 0 and at the point B the function is 0 . So this is the function $F(x)$. So by Rolle's theorem, if the function on the interval $A B$, if the function is continuous over the closed interval $A B$, differentiable at the open interval $A B$, and at the end point the function attains the value 0 , then there exists a point, say X_1 in between $A B$ such that the derivative of the function vanishes, such that $F'(X_1) = 0$. This is the mean value theorem, Rolle's theorem. Now again it is given that the functional value $F(A) = 0$, $F(B) = 0$, this is $F(x)$ function. $F(A) = 0$, $F(X_1) = 0$, and then $F(B) = 0$, this is our $F(x)$ function. So a function is vanishing at the point A , at the point X_1 ... at the point X_1 and at the point... at the point B . And it is given that $F(A) = 0$, $F(X_1) = 0$, $F(B) = 0$. So now apply the Rolle's theorem on the... for the function $f(x)$ on the interval A to X_1 and X_1 to B . So by Rolle's theorem, by this theorem there exist points X_1, X_2 , in the interval A to X_1 and X_1 to B , in the interval... X_1 to B , such that the derivative... second derivative of the function, or derivative of a prime vanishes at this point... vanishes at this point, okay.

Lecture 10

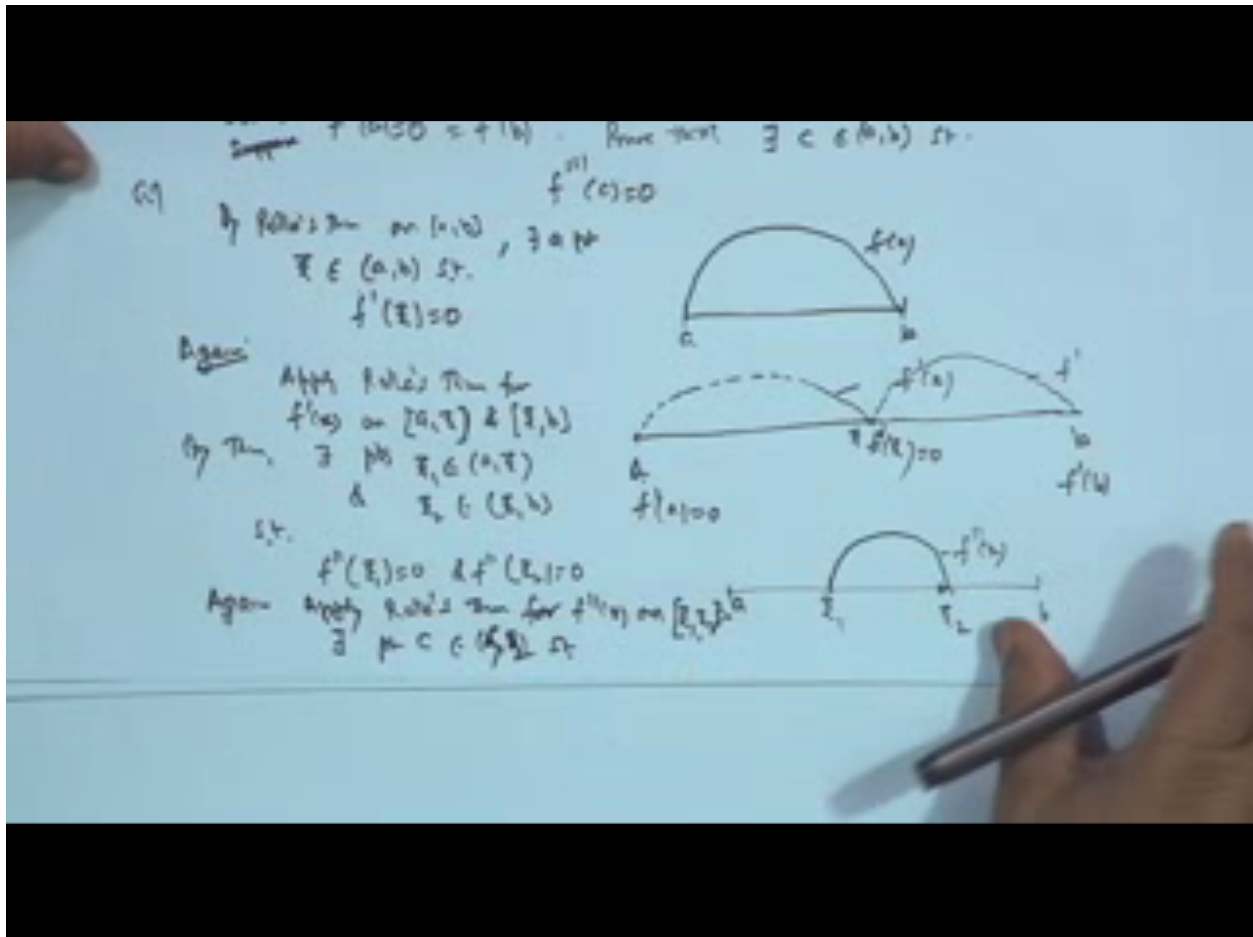

Tutorial - 10

Ex 1. A function f is thrice differentiable on $[a, b]$ s.t. $f(a) = f(b) = f'(a) = f'(b) = 0$.
 Prove that $\exists c \in (a, b)$ s.t. $f''(c) = 0$.

(i) By Rolle's Thm on $[a, b]$, $\exists a_1 \in (a, b)$ s.t. $f'(a_1) = 0$.

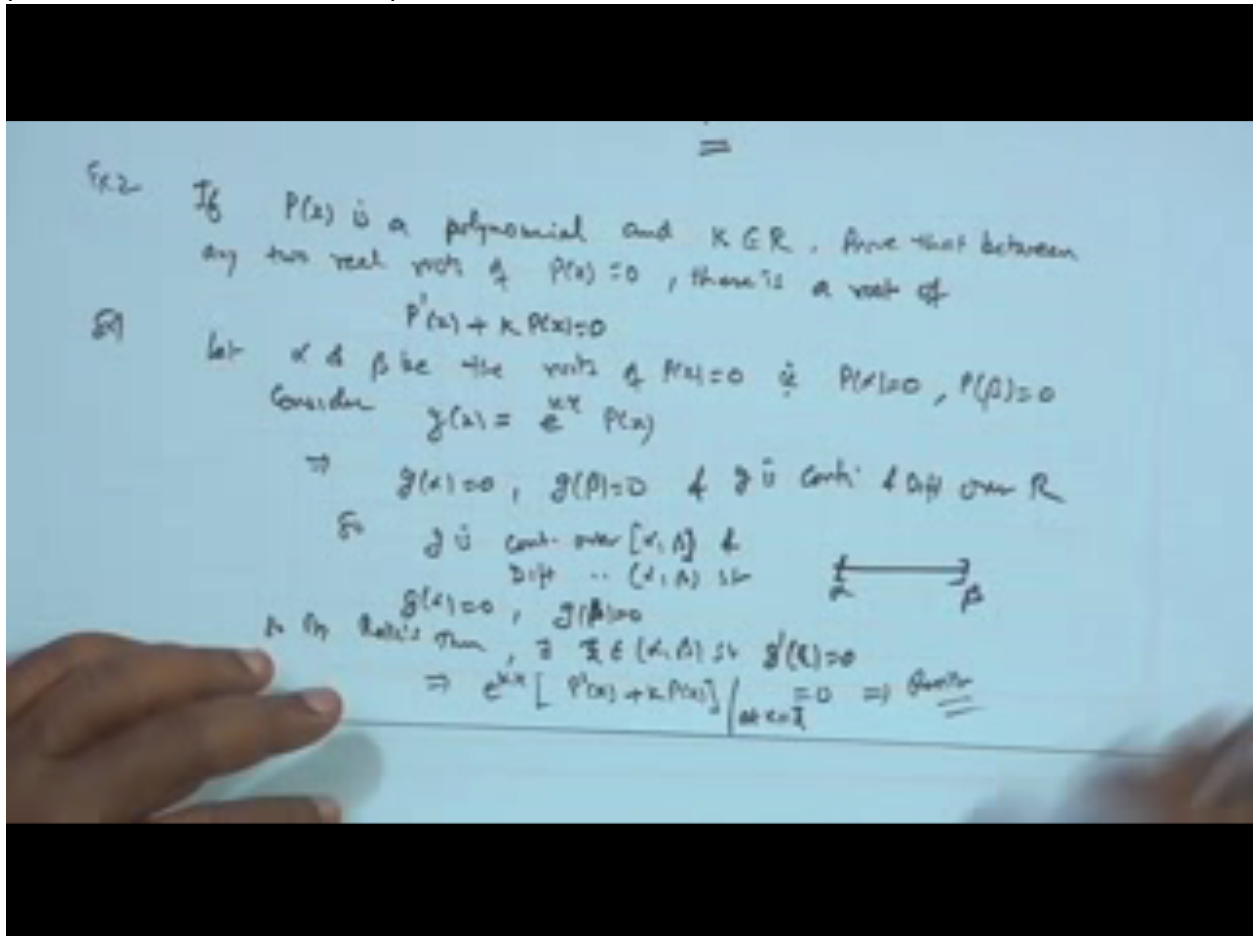

Again, Apply Rolle's Thm for $f'(x)$ on $[a, a_1]$ & $[a_1, b]$
 By Thm. \exists pts $x_1 \in (a, a_1)$ & $x_2 \in (a_1, b)$ s.t. $f''(x_1) = 0$ & $f''(x_2) = 0$.

So now again the figure is like this, a function this is A B, here is point X I 1, here is the point X I 2, the second derivative of the function, this is the F -- X, vanishes at the point X I 1, X I 2, function F is thrice differentiable. So this function F - is continuous and and differentiable. So again apply Rolle's theorem for the function F prime X on the interval X I 1, X I 2... X I 1, X I 2. So from here we get, there exists a point say C in the interval A B, such that... in fact interval XI1 XI2, such that XI1 XI2...
 (Refer Slide Time: 05:40)

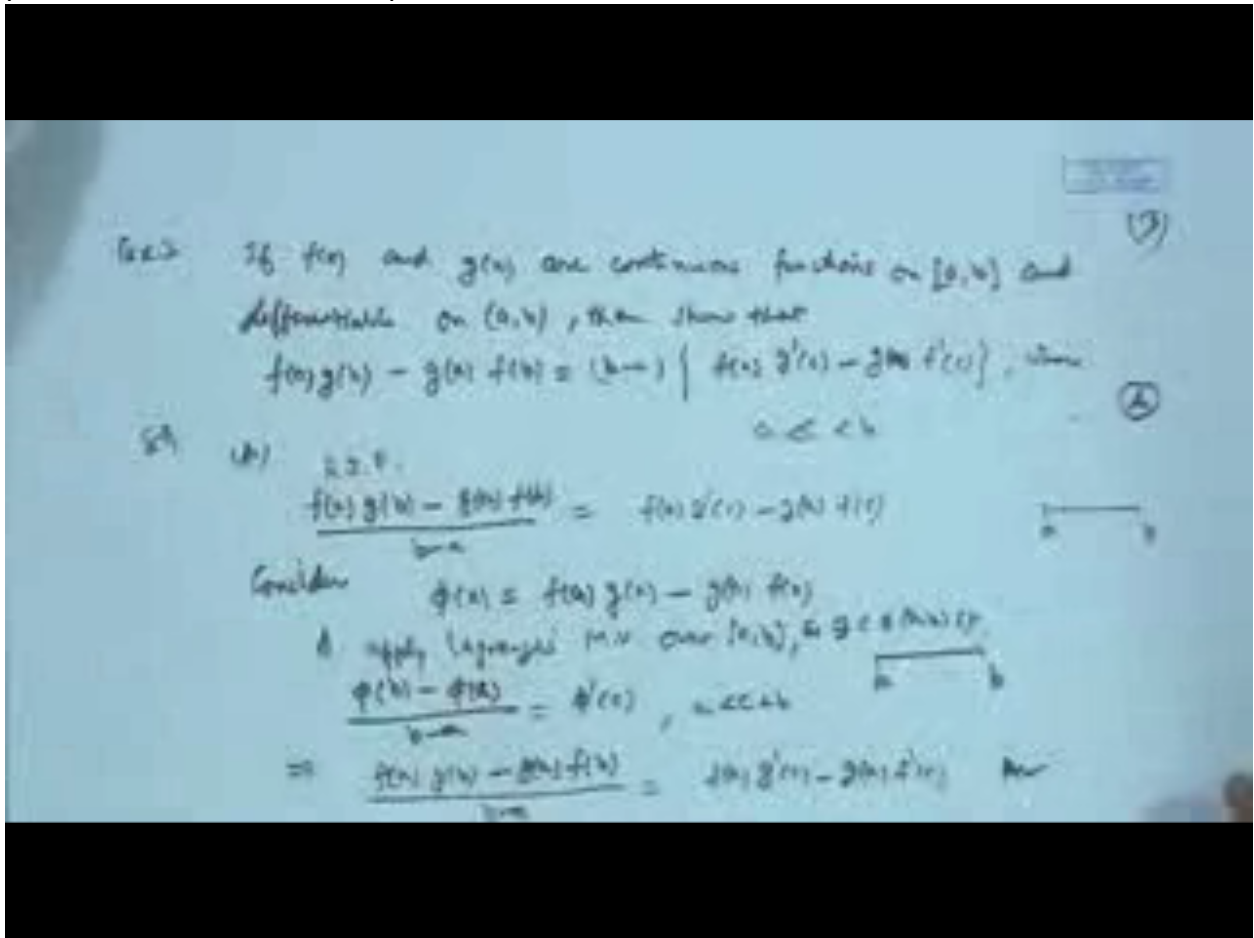

Such that the value of the function, the derivative of the function, third derivative at this point at C is 0. So C lying between ξ_1 ξ_2 , which is subset of A B, so the result follows from here, okay... results follows. So basically we are using the Rolle's theorem thrice and getting the reserves for this. Now next if $P(x)$ is a polynomial... $P(x)$ is a polynomial and K belongs to \mathbb{R} any real number, then prove that between two real roots of $P(x)$... between any two roots... two real roots of $P(x) = 0$ there is... there is a root of the equation $P(x) + K \cdot P'(x) = 0$. So $P(x)$ is a polynomial of this, prove that between any two real roots of $P(x) = 0$, there is a root for this. So let α and β be the roots of equation $P(x) = 0$. It means that is $P(\alpha) = 0$, $P(\beta) = 0$. Now construct a function of consider a function $G(x) = P(x) + K \cdot P'(x)$. Now α and β are the roots of this, therefore this implies that $G(\alpha) = 0$, $G(\beta) = 0$, because at the pointer α $P(\alpha) = 0$, at the point β the $P(\beta) = 0$, so $G(\alpha) = G(\beta) = 0$ and G is continuous... continuous and differentiable over the interval R , because polynomial is always a continuous differentiable function of a third function R and E to the power X is also continuous and differentiable therefore the function G is continuous and differentiable over the internal R . So if we take any interval, it remains continuous and differentiable of this. Now if we look the interval α to β , over this

close interval the function G is continuous, so G is continuous over the close interval $\alpha\beta$, and differentiable over the open interval $\alpha\beta$, such that G of α is 0, G of β is also 0. So by Rolle's theorem again... so by Rolle's theorem there exists a point... there exists a point ξ in between $\alpha\beta$ such that the derivative of G - at ξ is 0. But what is $G - X$, it's the same as $P - X$ to the power KX , $P - X$ plus K times PX at the point X equal to ξ , this vanishes. So this shows that this implies... this implies the result, because E to the power $\alpha\xi$ is not 0, therefore this has to be 0 and we get the result, okay. So this completes the result, their existence, okay.
(Refer Slide Time: 10:00)

Third, if F and G are continuous and differentiable on the close interval AB and differentiable on the open interval AB , then so that, F of A , G of B minus G of A , F of B equal to B minus A into F prime C minus G prime C , where C lies between A and B . So now function F and G are given to be continuous on the close interval AB , it's also differentiable then we have to prove this thing. Now if we look this one, then basically from the expression A , if we look this expression A , this can be expressed as, it can be rewritten as G of B minus G of A over B minus A , is this function, is it not, this we wanted to prove, required to prove with this one. So this suggests that if we construct the function, consider the

function $\Phi(x) = f(x)g(x) - g(x)f(x)$, then this function is continuous and differentiable over the interval $[a, b]$, because this function f and g are given to be continuous and differentiable and then at the point b , it has this value and at the point a it has the value 0. So it suggests that this function $\Phi(x)$ if we apply Lagrange's mean value theorem for the function $\Phi(x)$ over the interval $[a, b]$ then we may get this result, okay. So consider this function and apply Lagrange's mean value theorem over the interval $[a, b]$. So what we get $\Phi(b) - \Phi(a)$ over $b - a$, so then we get this thing, where c is a point in between $[a, b]$, so there exists c in the interval $[a, b]$, such that this is (inaudible). Now substitute the value and get the result. So $\Phi(b)$ means $f(b)g(b) - g(b)f(b)$, $\Phi(a)$ means $f(a)g(a) - g(a)f(a)$, and what is the derivative of this function $f'(x)g(x) + f(x)g'(x) - g'(x)f(x) - g(x)f'(x)$, so $f'(x)g(x) - g'(x)f(x)$ and that is the answer which we wanted okay. So sometimes we have to see the answer and according to the expression one can decide that can we have a suitable function so that after applying either Lagrange's mean value theorem or Rolle's theorem, we can get immediately result, okay, so that is what.
 (Refer Slide Time: 14:10)

Okay now, prove that... prove that if the equation $x^N + a_{N-1}x^{N-1} + \dots + a_1x + a_0 = 0$ has a positive

root... has a positive root say x_0 then... then the equation... then the equation and $A x_0^{N-1} + A_1 x_0^{N-2} + \dots + A_{N-1} x_0 = 0$ has a positive root... root less than x_0 . I think that's very easy question, solution this is the interval $(0, x_0)$ and here is the point x_0 . The function has given a positive root this, what is the function $f(x) = A x^N + A_1 x^{N-1} + \dots + A_{N-1} x$. If I take x_0 to the power N , plus $A_1 x_0^{N-1}$, plus $A_{N-1} x_0$, then at the point 0 it is 0 , at the point x_0 it is also 0 , because it has a root x_0 has a group of this equation. So function is continuous over the interval 0 to x_0 , differentiable on the open interval 0 to x_0 , so by the Rolle's theorem, Rolle's theorem, there exists a point C in the interval 0 to x_0 such that the derivative of this function vanishes, but derivative means $N A x_0^{N-1} + (N-1) A_1 x_0^{N-2} + \dots + A_{N-1} = 0$, where C is positive and that's the answer, which we are looking, okay. So this will be... (Refer Slide Time: 17:15)

17:13 / 26:59

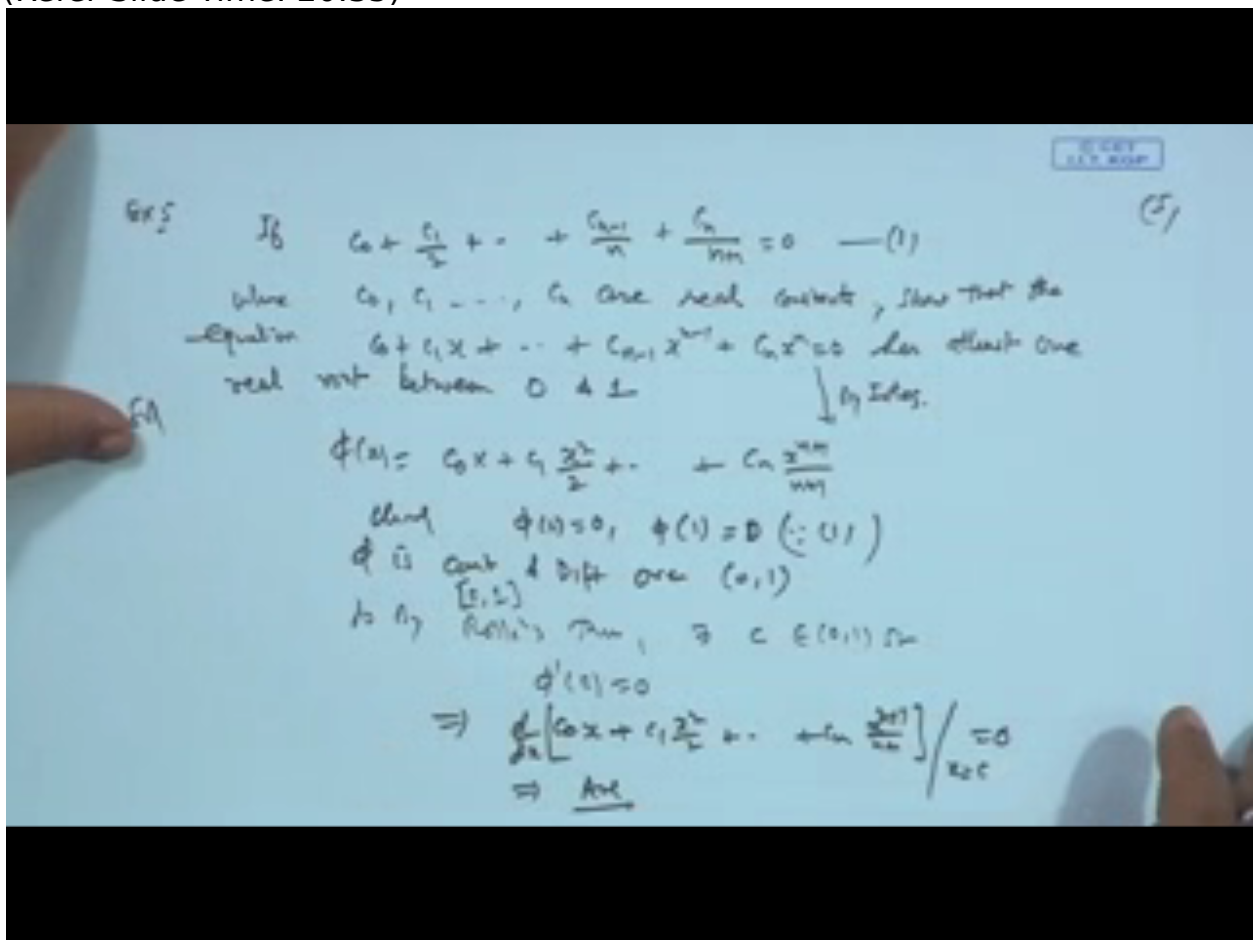

Ex. 4. Prove that if the equation
 $a_0 x^N + a_1 x^{N-1} + \dots + a_{N-1} x = 0$ has a positive root x_0 , then
the equation
 $N a_0 x^{N-1} + (N-1) a_1 x^{N-2} + \dots + a_{N-1} = 0$
has a positive root less than x_0 .

Sol. $f(x) = a_0 x^N + a_1 x^{N-1} + \dots + a_{N-1} x$
 $f(0) = 0 = f(x_0)$

f is continuous on $[0, x_0]$, diff. on $(0, x_0)$. By Rolle's
Then $\exists c \in (0, x_0)$ st
 $f'(c) = 0 \Rightarrow N a_0 c^{N-1} + (N-1) a_1 c^{N-2} + \dots + a_{N-1} = 0$
 $c > 0$

Another exercise, if $C x_0^N + C_1 x_0^{N-1} + C_2 x_0^{N-2} + \dots + C_{N-1} x_0 = 0$, where C naught, $C_1 C_2 \dots C_{N-1}$ are real constants... are real constants then show that... show that the equation... equation $C x_0^N + C_1 x_0^{N-1} + C_2 x_0^{N-2} + \dots + C_{N-1} x_0 = 0$ has at least one real root between 0 and 1 . Solution, so this is given B_1 this function has at least one

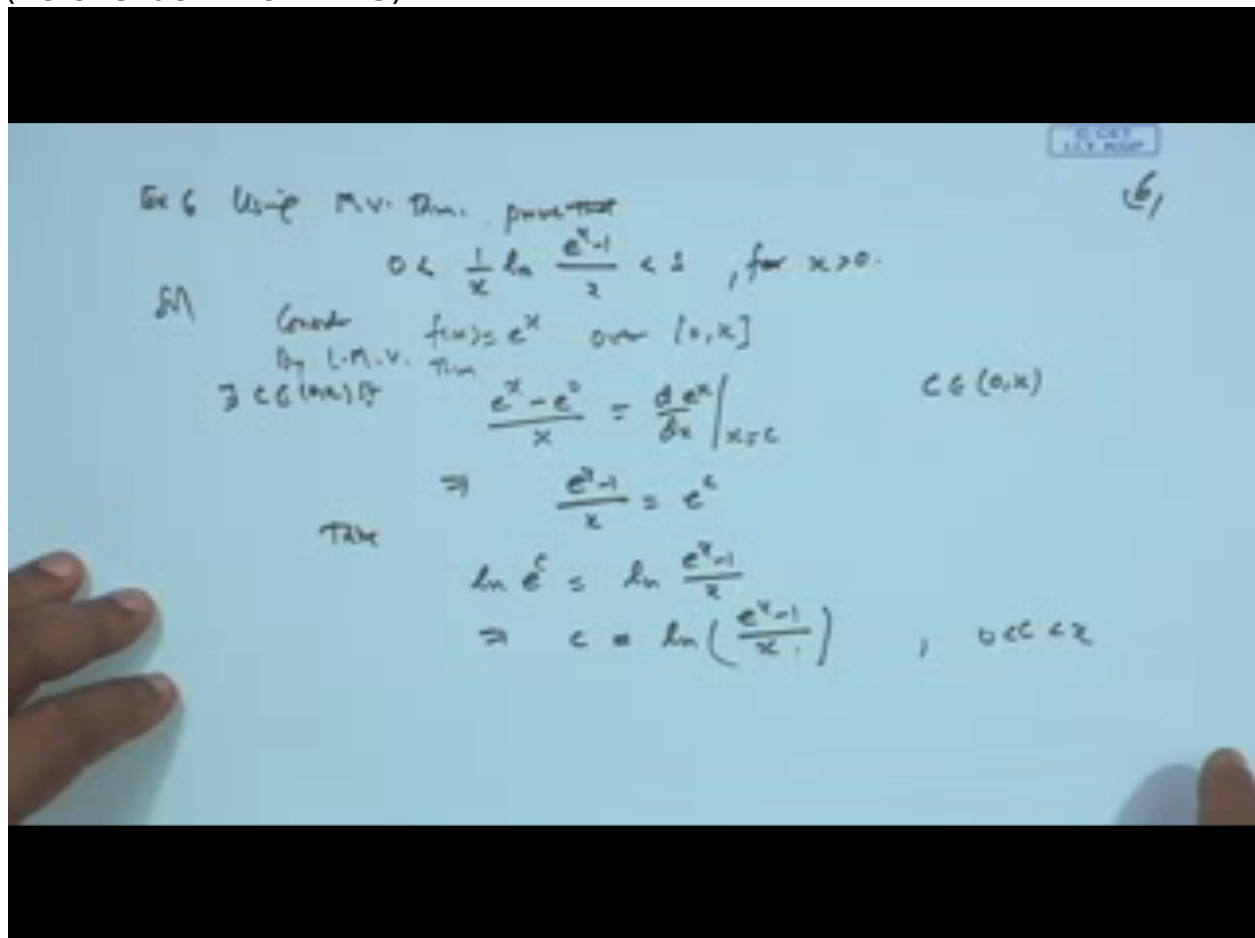

real root in $(0, 1)$, so if we look the function $\Phi(x)$, what is this function is, construct the function $\Phi(x)$ as $C_0 x + C_1 x^2 + \dots + C_n x^{n+1}$ by 2 plus $C_n x$ to the power $n + 1$ by $n + 1$. This basically I have taken from here by integrating. Because when you consider this function and apply the Rolle's theorem, then finally result comes as a derivative of the function, so if I prove that this function Φ satisfies all the conditions of the Rolle's theorem over the interval 0 to 1 then there will be a point c some point where the derivative of this function vanishes, it means this will come, okay. So clearly $\Phi(0) = 0$, $\Phi(1) = 0$ because of the condition... because of the condition 1 , because of 1 , is it not, because of this condition this vanishes. Therefore Φ is also continuous and differentiable over the interval $0, 1$ continuity has the close interval $0, 1$ differentiability of interval $0, 1$. So by Rolle's theorem... Rolle's theorem, there exists a point c in the interval $0, 1$, where the derivative of this function vanishes, but this derivative means c not x , c naught derivative of this, so derivative of this $C_0 x + C_1 x^2 + \dots + C_n x^{n+1}$ by $2 C_n x^{n+1}$ by $n + 1$, at the point x equal to c vanishing and that is the result. So answer okay, let's do that part, answer is this.
(Refer Slide Time: 20:35)

Now using the mean value theorem, we can also obtain or we can also derive certain inequality, say using mean value theorem prove that $0 < c < 1$ by

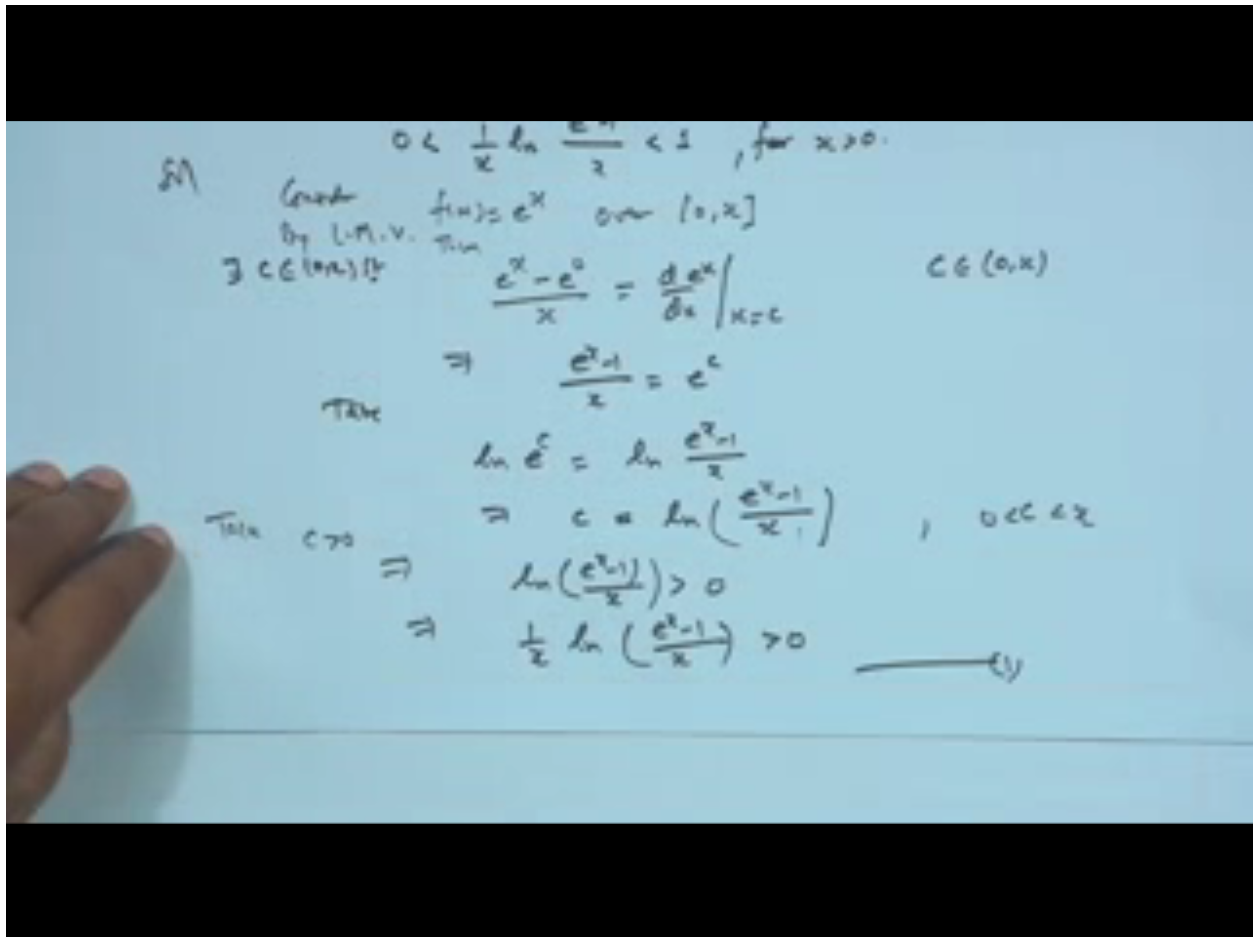

$\frac{\ln e^x}{x}$ to the power x minus 1 divided by x is less than 1 for x greater than 0. So let's see the solution for this. This inequality we wanted to drive with the help of mean value theorem, in fact the Lagrange's mean value theorem will help you. So consider the function $f(x)$ equal to e^x and over the interval 0 to x , then by Lagrange's mean value theorem... Lagrange's mean value theorem, we get the value of the function at a point x minus value of difference at the point 0 divided by x is equal to the derivative of the function e^x at the point x equal to e^c , where the c lies between 0 and x , okay, c lies between 0 and x . So by mean value theorem, there exist a c in the interval 0 and x , such that this is gathered, and this is equal to e^c to the power x minus 1 by x is equal to e^c , take the log, so we get $\ln \left(\frac{e^x - 1}{x} \right) = \ln e^c$ and this implies $c = \ln \left(\frac{e^x - 1}{x} \right)$, where the c lies between 0 and x .

(Refer Slide Time: 22:45)

Now if we take c to be greater than 0, then obviously this inequality $\ln \left(\frac{e^x - 1}{x} \right) > 0$, this will be greater than 0, greater than 0, but x is also positive so this implies that $\frac{1}{x} \ln \left(\frac{e^x - 1}{x} \right) > 0$ will also be positive. So that is the first part of this result.

(Refer Slide Time: 23:15)

The second side is often like this, since C is less than 1... C is less than 1... less than sorry, X... less than X, therefore C means what, this one E to the power X minus 1 by X log of this, this is log, so this implies the log of LN E to the power X minus 1 by X is less than X, therefore 1 by X LN E to the power x minus 1 by X is still less than 1. So this proves the second part of it and this completes the results for it, okay. And next is say FX is, prove the... prove that... prove that if FX is 1 over root X and GX is equal to root X, then prove that there exist... there exist... prove that there exists a C such that... such that C is the geometric mean of AB, so this way. So let us see, apply the continue, Cauchy's mean value theorem. What the Cauchy's mean value theorem says, the Cauchy's mean value theorem is if F and G are continuous and different over the interval say AB, differentiable on the open interval AB G prime X is not equal to 0 then there exists a point C in the interval AB such that F of X, F of B minus F of A over G of B minus G of A is the derivative F - C over G - C, this is the mean value theorem. So apply this here, FX and GX are such, so find out the F prime C, so by Cauchy's mean value theorem over the interval say AB, AB we get from here is 1 by root B minus 1 by root A, divide by root B minus root A is the derivative F prime C over G prime C and this is equal to nothing but 1 by this 1... this is root AB... this root AB 1 over root AB okay, equal to what is the F prime C, F prime C will be half C to the

power minus 3 by 2 over this will be half by root 2 by root C. So from here we get C is equal to root AB and that's the answer for it. Thank you very much, thanks.
