Now what we do is in the step 3 we remove the open interval, remove the segment  $U_j, V_j$  from the closed interval  $A, B$ , it means what we are doing is that this is our interval  $A, B$ , okay, and here is the point say  $U_1, B_1, U_2$  sorry  $U_1, V_1, U_2, V_2$  and like this, suppose these are the points say like  $U_n$  say  $V_n$ .

(Refer Slide Time: 01:09)

Then what we do is we are removing this portion, this portion we are removing, so we are getting now after remove it  $A$  into  $U_1, A U_1$ , this 1, then start with  $V_1, U_2$ , and like this, then

start with  $V_2$  and continue this way and up to here say  $B$ , so this set  $K$  which is, in which these things are not available, these things are not available,  
 (Refer Slide Time: 01:47)

Sum of the corresponding differences  $\alpha(v_j) - \alpha(u_j) < \epsilon$

Step II We can place these interval in such way that every pt of  $E \cap (a,b)$  lies in the interior of some  $[u_j, v_j]$

Step III We remove the segment  $(u_j, v_j)$  from  $[a,b]$

$E \cap (a,b) = \{x_i : f \text{ is discontinuous at } x_i\}$

The diagrams show a horizontal line segment from  $a$  to  $b$ . In the first diagram, several small intervals  $[u_j, v_j]$  are placed along the line, each containing a point  $x_i$  from the set  $E$ . In the second diagram, these intervals are removed from the line, leaving gaps. The remaining parts of the line are labeled as  $K$ . The third diagram shows the intervals  $[u_j, v_j]$  again, but now they are closed intervals, and the gaps between them are also closed, forming a compact set  $K$ .

okay, so this set  $K$  forms a compact set. So once we remove the segment  $UJ, VJ$  from here, then the remaining set  $K$  is compact, because it is a finite union of the compact closed and compact set intervals like this, so it is a compact set, is compact or compact set, is okay?  
 (Refer Slide Time: 02:18)

Sum of the corresponding differences  $\alpha(v_j) - \alpha(u_j) < \epsilon$

Step II We can place these interval in such way that every pt of  $E \cap (a,b)$  lies in the interior of some  $[u_j, v_j]$

Step III We remove the segment  $(u_j, v_j)$  from  $[a,b]$ , the remaining set  $K$  is Compact: set

$E \cap (a,b) = \{x_i : f \text{ is discontinuous at } x_i\}$

The diagrams show a horizontal line segment from  $a$  to  $b$ . In the first diagram, several small intervals  $[u_j, v_j]$  are placed along the line, each containing a point  $x_i$  from the set  $E$ . In the second diagram, these intervals are removed from the line, leaving gaps. The remaining parts of the line are labeled as  $K$ . The third diagram shows the intervals  $[u_j, v_j]$  again, but now they are closed intervals, and the gaps between them are also closed, forming a compact set  $K$ .

Now function  $F$  is given to be continuous, since  $F$  is continuous over  $K$  because that point of discontinuity we have already removed, so  $F$  is continuous over  $K$  and  $K$  is compact set so every continuous function on a compact set is uniformly continuous,

(Refer Slide Time: 02:39)

Sum of the corresponding differences  $(v_j - u_j) = \dots$

**Step I** We can place these intervals in such a way that every pt of  $E \cap (a, b)$  lies in the interior of some  $[u_j, v_j]$

**Step II** We remove the segment  $(u_j, v_j)$  from  $[a, b]$ , the remaining set  $K$  is Compact set

Since  $f$  is continuous over  $K$

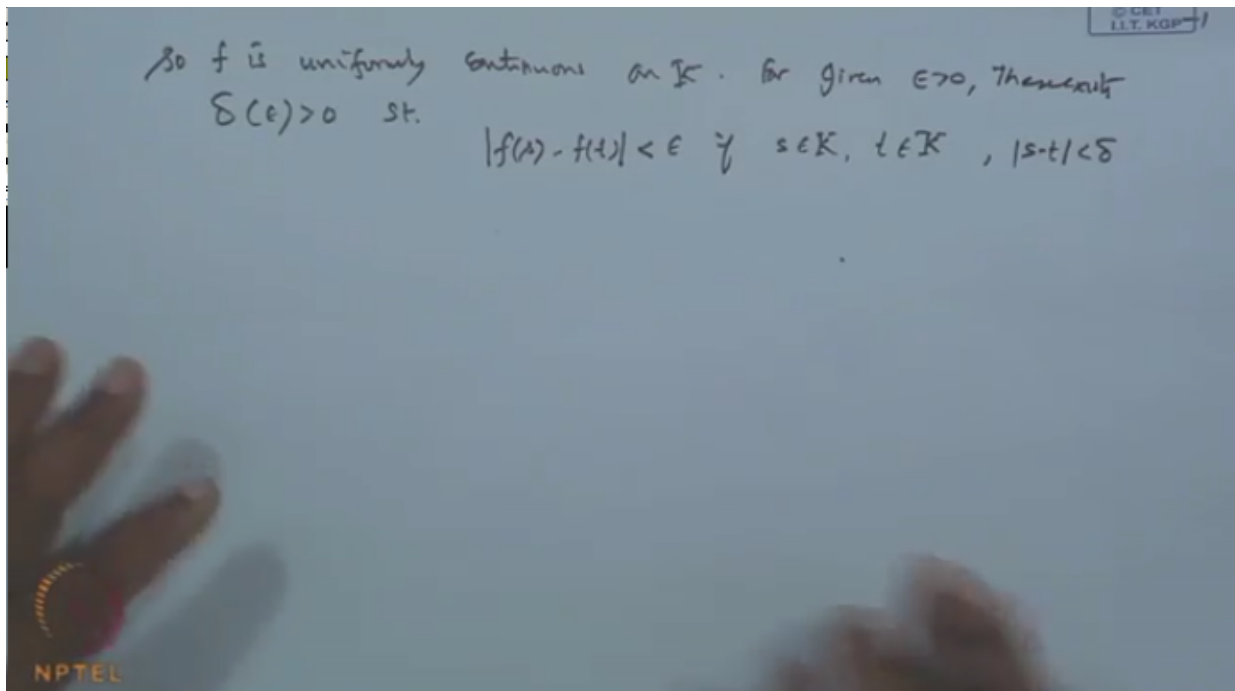

$E \cap (a, b) = \{x_i : f \text{ is discontinuous at } x_i\}$

NPTEL

so  $F$  will be, so  $F$  is uniformly continuous function on  $K$ , clear.

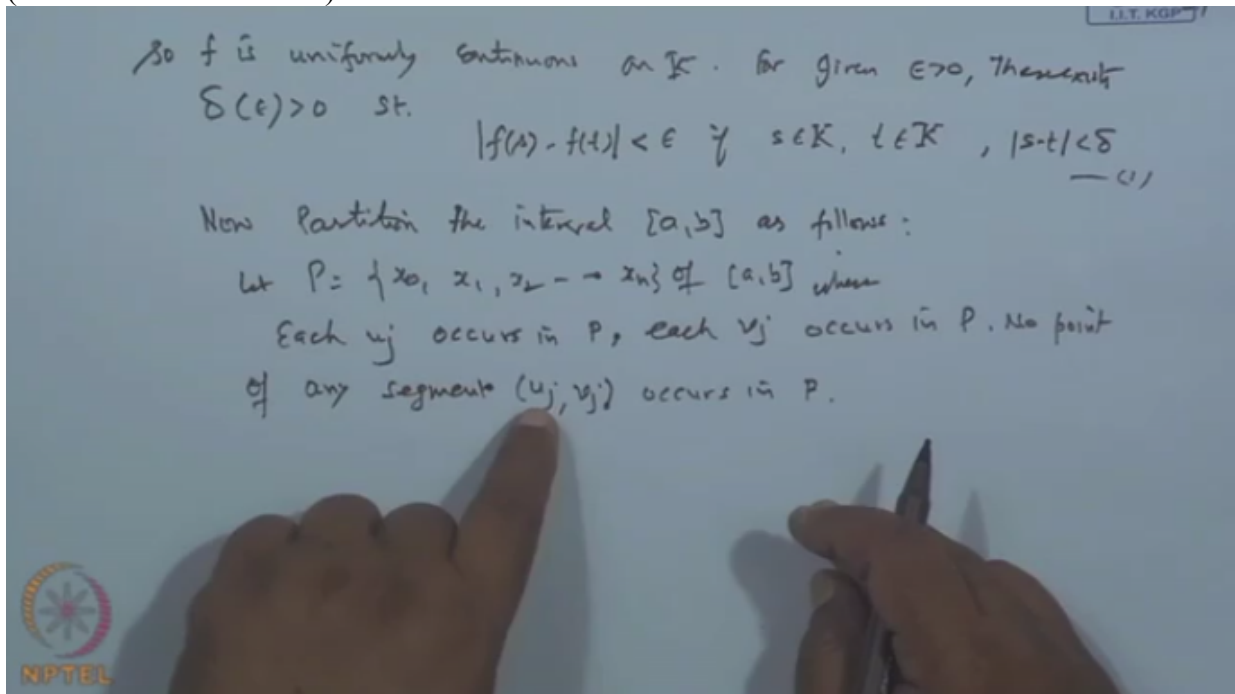

So by definition what is  $F$  is uniform means? So for a given epsilon greater than 0, so for given epsilon greater than 0 there exists a delta which depends only on epsilon not the point greater than 0 such that the mod of  $F(s) - F(t)$  this will remain less than epsilon if  $S$  belongs to  $K$ ,  $T$  belongs to  $K$ , and mod of  $S - T$  is less than delta, by definition of the uniform continuity, okay let it be 1, okay.

(Refer Slide Time: 03:46)

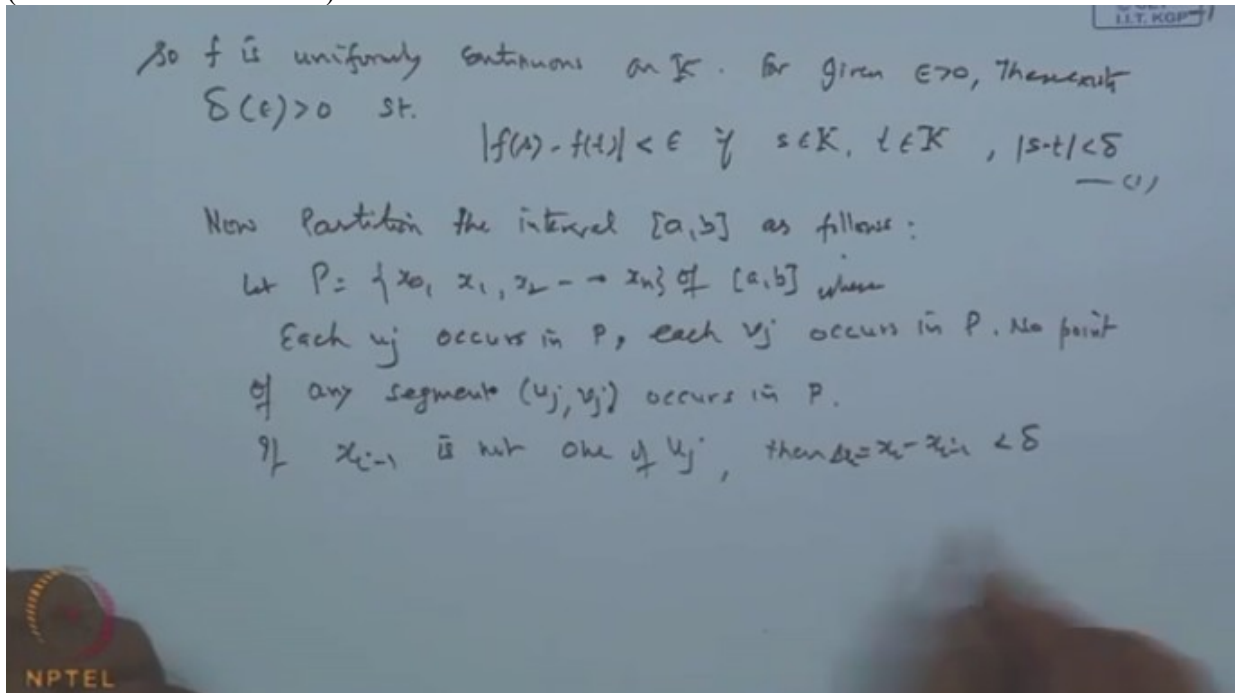

Now let us partition, now partition the interval  $(A, B)$  as follows, suppose  $P$  is the partition, let  $P$  is the partition  $x_0, x_1, x_2, \dots, x_n$  of  $(A, B)$ , then  $B$  takes such partition that each  $U_j, V_j$  is a partition where  $U_j$ , each  $U_j$  occurs in  $P$ , each  $V_j$  occurs in  $P$  means this  $U_1, E_2, E_1, V_1, V_2, V_n$  these are the one of the points of the partitioning point of this interval  $(A, B)$ , and no point of any segment  $(U_j, V_j)$  this open segment occurs in  $P$ , this is the restriction we are putting,

(Refer Slide Time: 05:20)

we are choosing the partition in such a way that the corner points of these sub intervals which are covering the point of discontinuities are basically coinciding with the partitioning point, but none of the point in between in this, inside this interval all the partitioning point, are the points of the partition this is one thing.

Second thing in incase if XI-1 suppose is not one of the UJ, because this might be possible, the number of the points are finite, may be the number of points are not as efficient as the partitioning point is there, so some of the XI's will remain untouched, so if XI, MI is not one of the user, then what we do is then we put the restriction here that the XI-1 that is the delta XI this should be less than delta, this is our restriction, okay,  
(Refer Slide Time: 06:26)

so once you have partitioning this point it means, okay, now we get this, so this is our X naught, X1, X2, X3, XN and so on, say this is A, this is B, okay, and then we are coinciding this as suppose U naught, U1 and so on continue suppose here is UJ, and after this we are not getting anything, and the points in between UJ are not there, one thing.

So let us see suppose we take any interval clearly over any sub intervals MI - small mi this will remain less than equal to 2M, why? Because what is our M? M is the supremum value we have chosen,  
(Refer Slide Time: 07:30)

So  $f$  is uniformly continuous on  $K$ . for given  $\epsilon > 0$ , there exists  $\delta(\epsilon) > 0$  st.

$$|f(s) - f(t)| < \epsilon \quad \forall s \in K, t \in K, |s-t| < \delta \quad (1)$$

Now partition the interval  $[a, b]$  as follows:

Let  $P = \{x_0, x_1, x_2, \dots, x_n\}$  of  $[a, b]$  where

Each  $u_j$  occurs in  $P$ , each  $v_j$  occurs in  $P$ . No point of any segment  $(u_j, v_j)$  occurs in  $P$ .

If  $x_{i-1}$  is not one of  $u_j$ , then  $\delta = x_i - x_{i-1} < \delta$

Thus,  $M_i - m_i \leq 2M$

NPTEL

this is  $M$  is the supremum value over interval so if I consider the  $X_i - X_{i-1}$  clearly because over the interval, over  $X_{i-1}$  to  $X_i$  the minimum value of the function is  $m_i$ , supremum value is  $M$ , so  $M_i$  as well as a small  $m_i$  both are less than equal to  $M$ , so  $M_i - m_i$  is less than equal to  $2M$ , (Refer Slide Time: 07:54)

© GET I.I.T. KGP

So  $f$  is uniformly continuous on  $K$ . for given  $\epsilon > 0$ , there exists  $\delta(\epsilon) > 0$  st.

$$|f(s) - f(t)| < \epsilon \quad \forall s \in K, t \in K, |s-t| < \delta \quad (1)$$

Now partition the interval  $[a, b]$  as follows:

Let  $P = \{x_0, x_1, x_2, \dots, x_n\}$  of  $[a, b]$  where

Each  $u_j$  occurs in  $P$ , each  $v_j$  occurs in  $P$ . No point of any segment  $(u_j, v_j)$  occurs in  $P$ .

If  $x_{i-1}$  is not one of  $u_j$ , then  $\delta = x_i - x_{i-1} < \delta$

Thus,  $M_i - m_i \leq 2M$

$\therefore$  over  $[x_{i-1}, x_i]$ ,  $M_i, m_i \leq M$

NPTEL

this is true for each  $I$ , for every  $I$ , this is true.

And further if  $X_i$  is not one of the point, if  $X_{i-1}$  is not one of the point of  $U_j$ , (Refer Slide Time: 08:26)

© CEE  
I.I.T. KGP

So  $f$  is uniformly continuous on  $K$ . for given  $\epsilon > 0$ , there exists  $\delta(\epsilon) > 0$  st.

$$|f(s) - f(t)| < \epsilon \quad \forall \quad s \in K, t \in K, |s-t| < \delta \quad \text{--- (1)}$$

Now Partition the interval  $[a, b]$  as follows:

Let  $P = \{x_0, x_1, x_2, \dots, x_n\}$  of  $[a, b]$  where

Each  $u_j$  occurs in  $P$ , each  $v_j$  occurs in  $P$ . No point of any segment  $(u_j, v_j)$  occurs in  $P$ .

If  $x_{i-1}$  is not one of  $u_j$ , then  $\Delta x_i = x_i - x_{i-1} < \delta$

Check,  $M_i - m_i \leq 2M$  for every  $i$ ,  $\epsilon = x_0 < x_1 < \dots < x_n = b$

$\therefore$  over  $[x_{i-1}, x_i]$ ,  $M_i, m_i \leq M$

$\Rightarrow x_{i-1}$  is not one of the pts of  $u_j$

unless this is not one of the point then the difference between  $M_i - m_i$  small  $m_i$ , this difference can be made less than equal to epsilon, why?  
(Refer Slide Time: 08:41)

© CEE  
I.I.T. KGP

So  $f$  is uniformly continuous on  $K$ . for given  $\epsilon > 0$ , there exists  $\delta(\epsilon) > 0$  st.

$$|f(s) - f(t)| < \epsilon \quad \forall \quad s \in K, t \in K, |s-t| < \delta \quad \text{--- (1)}$$

Now Partition the interval  $[a, b]$  as follows:

Let  $P = \{x_0, x_1, x_2, \dots, x_n\}$  of  $[a, b]$  where

Each  $u_j$  occurs in  $P$ , each  $v_j$  occurs in  $P$ . No point of any segment  $(u_j, v_j)$  occurs in  $P$ .

If  $x_{i-1}$  is not one of  $u_j$ , then  $\Delta x_i = x_i - x_{i-1} < \delta$

Check,  $M_i - m_i \leq 2M$  for every  $i$ ,  $\epsilon = x_0 < x_1 < \dots < x_n = b$

$\therefore$  over  $[x_{i-1}, x_i]$ ,  $M_i, m_i \leq M$

$\Rightarrow x_{i-1}$  is not one of the pts of  $u_j$  then  $M_i - m_i \leq \epsilon$

Because of this part, because a function is continuous as well as uniformly continuous over the  $K$ , so if the point  $x_i - x_{i-1}$  less than delta, if this is because we have put this  $x_i$ , if  $x_i$  is not one of the point then this difference is less than delta, so because of the one this difference should be less than epsilon, so  $M_i - m_i$  small  $m_i$  will be less than epsilon, okay, so that for each one this will be less than equal to epsilon.

Hence if we constructed the proof upper sum - lower sum, so upper sum of the function  $F$  with respect to  $\alpha$  over the partition that for  $P$  - lower sum of the function  $F$  with respect to  $\alpha$  over the partition  $P$ , this is basically what  $\sum_{i=1}^n (M_i - m_i) \Delta \alpha_i$ , which can be break up as  $\sum_{i=1}^n M_i \Delta \alpha_i - \sum_{i=1}^n m_i \Delta \alpha_i$ , we got that drop till double, okay, this which are dropped, so in this case is over  $K$  this is less than  $\epsilon$ , so we get  $\epsilon$  into  $\sum$  of this part, but  $\sum$  of this  $\Delta \alpha_i$ ,  $i$  is 1 to  $N$  is nothing but the  $\alpha(B) - \alpha(A)$ , so this will, and this part over this here, already we have, function is bounded, so  $+M_i$  is less than equal to  $2M$ , and since  $\sum$  of  $\Delta \alpha_i$ ,  $\alpha(B) - \alpha(A)$  - this total is less than  $\epsilon$ , this is because of the continuity this sum of these corresponding is less than  $\epsilon$ , so we get from here is that this is less than  $\epsilon$ , okay, and this part will be  $\epsilon \alpha(B) - \epsilon \alpha(A) + 2M \epsilon$   $\epsilon$ , but  $\epsilon$  is arbitrarily small number, so this shows that the right hand side will go to 0 the left hand side, so  $\alpha(F)$  will be the element of  $R(\alpha)$ , this is proved that, okay, so this is what proof.

(Refer Slide Time: 11:20)

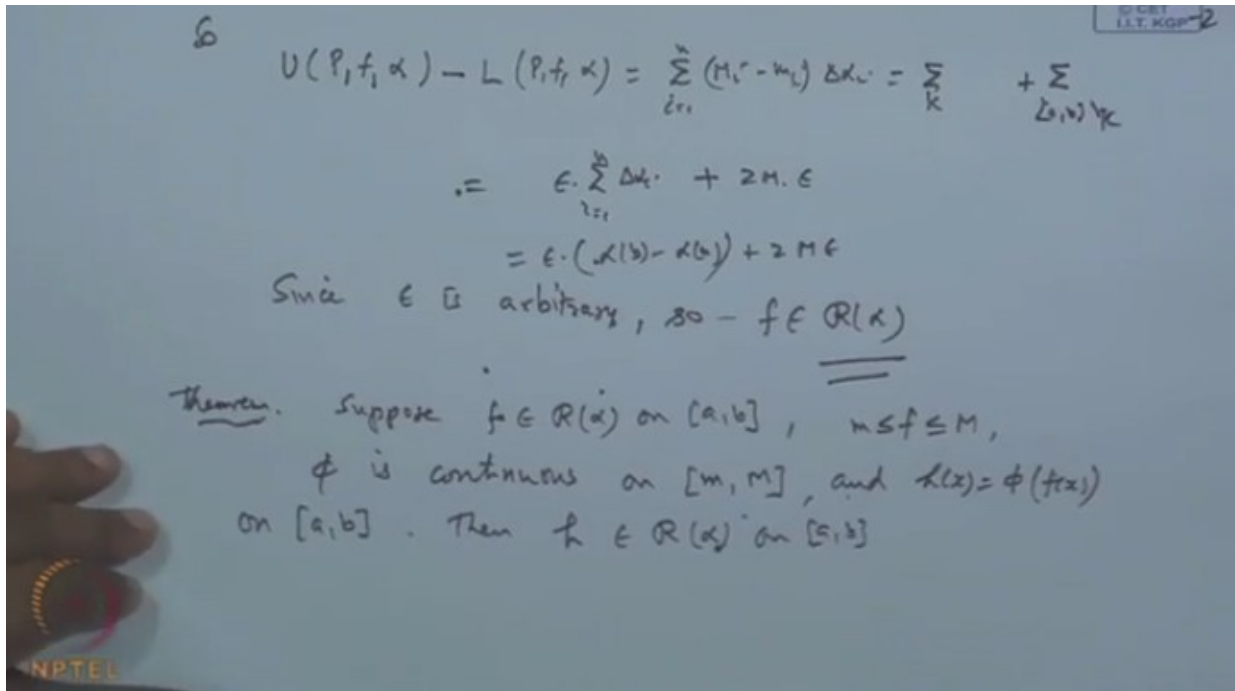

$$U(P, f, \alpha) - L(P, f, \alpha) = \sum_{i=1}^n (M_i - m_i) \Delta \alpha_i = \sum_K + \sum_{(A, B) \setminus K}$$

$$= \epsilon \sum_{i=1}^n \Delta \alpha_i + 2M \epsilon$$

$$= \epsilon (\alpha(B) - \alpha(A)) + 2M \epsilon$$
 Since  $\epsilon$  is arbitrary, so  $f \in R(\alpha)$

Now another results also which is interesting, the result says suppose  $F$  is in  $R(\alpha)$  on the closed interval  $(A, B)$ , Riemann Steiltjes Integral with respect to  $\alpha$  over that interval  $(A, B)$ , and  $F$  is bounded function, bounded by say  $m$  in capital  $M$ ,  $\phi$  is continuous on the closed interval  $m$  and capital  $M$ , this is  $\phi$ . Then an  $H$ ,  $H(x)$  is  $\phi$  of  $F(x)$  on the closed interval  $(A, B)$ , then this result says the  $H$  belongs to  $R(\alpha)$  that Riemann Steiltjes integral on  $(A, B)$ , (Refer Slide Time: 12:32)

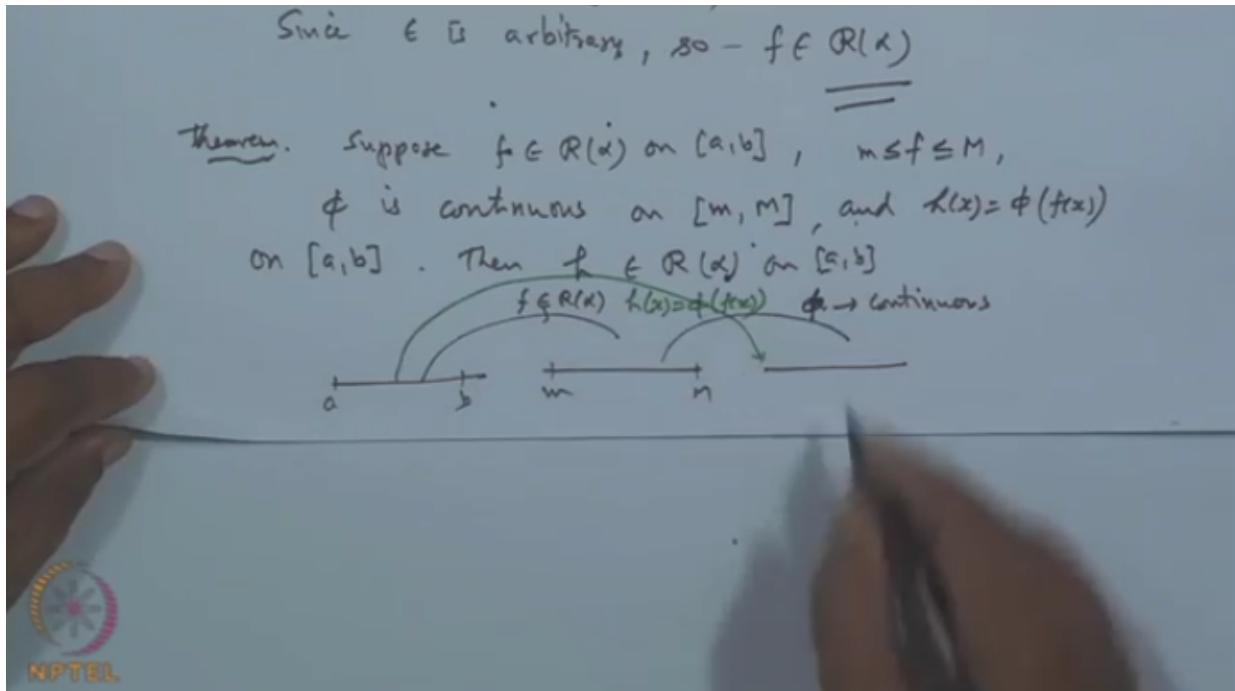

so if function  $F$  is Riemann integral function and  $\phi$  is a continuous function on the  $(m, M)$  that is where the function have a range set, range of the set  $F$  is  $(m, M)$  interval, then the composition of this function continuous, image of a Riemann Steiltjes integral function will be Riemann Steiltjes integral, that is what it says, okay.

So this is just like that here we are taking this function this is our interval  $(A, B)$ , function  $F$  is given, so here is our  $m$  and capital  $M$  where the function  $F$  is attains the minimum and maximum value, and over this is the function  $H$  is defined, okay, so what is  $F$ ? When we combined the  $\phi$  composition  $F(x)$  then it will transfer directly from here to here which is  $H$  composition  $H(x) = \phi$  composition  $F(x)$ .

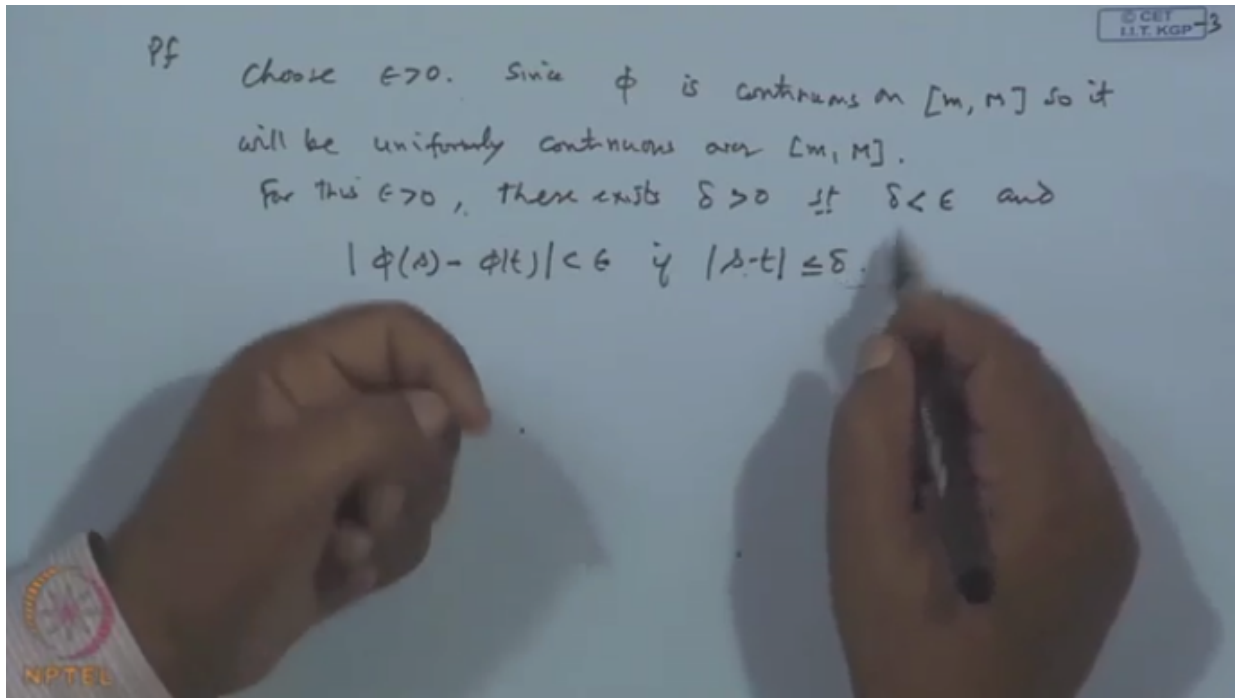

And if this is in RL, this function  $\phi$ , oh this is  $\phi$  sorry, this is  $\phi$ , and if this  $\phi$  is continuous and this is continuous, this is in  $R(\alpha)$ ,  
(Refer Slide Time: 14:09)

then our  $h$  will be in  $R(\alpha)$  that is what it says, okay, so let's see the proof of it, choose  $\epsilon$  greater than 0, okay.

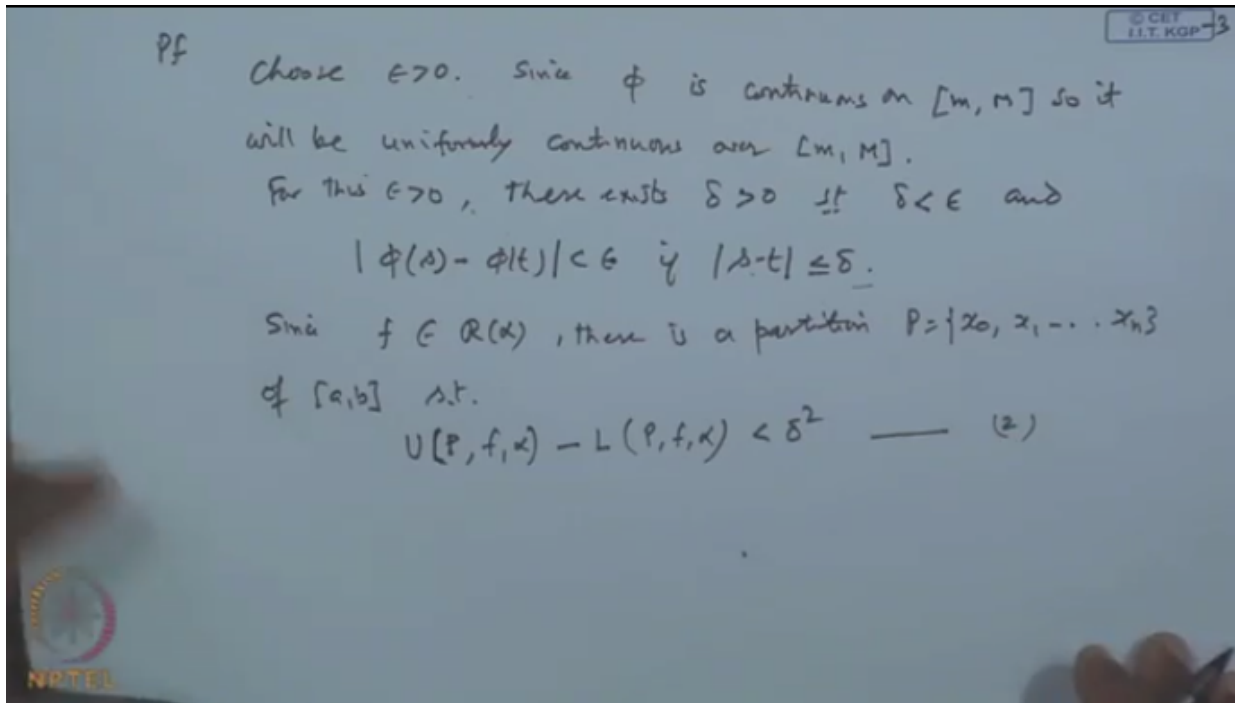

Now given that  $\phi$ , since  $\phi$  is continuous on the closed interval  $m$  and capital  $M$ , so it will be uniformly continuous over this interval  $m$  and capital  $M$ , because every continuous function over a compact set is uniformly continuous, so by definition  $\epsilon$  we have already chosen, so let us choose the  $\delta$ , so for this  $\epsilon$  greater than 0 which is chosen earlier there exists a  $\delta$  greater than 0, such that now I'm putting the restriction on this  $\delta$  is smaller than  $\epsilon$ , because this is any  $\delta$  is true then all the  $\delta$  which are less putting  $\delta$  to be less than  $\epsilon$  this image will go there, okay, so let us put and take the  $\delta$  to be less than  $\epsilon$ , and  $\phi(s) - \phi(t)$  is less than  $\epsilon$ , if  $|\phi(s) - \phi(t)|$  is less than equal to  $\delta$ , what you say is because  $\phi$  is uniformly continuous, so for any  $\epsilon$  greater than 0 there exists a  $\delta$  such that image of this any point in which satisfy this condition must fall within this range.

(Refer Slide Time: 16:06)

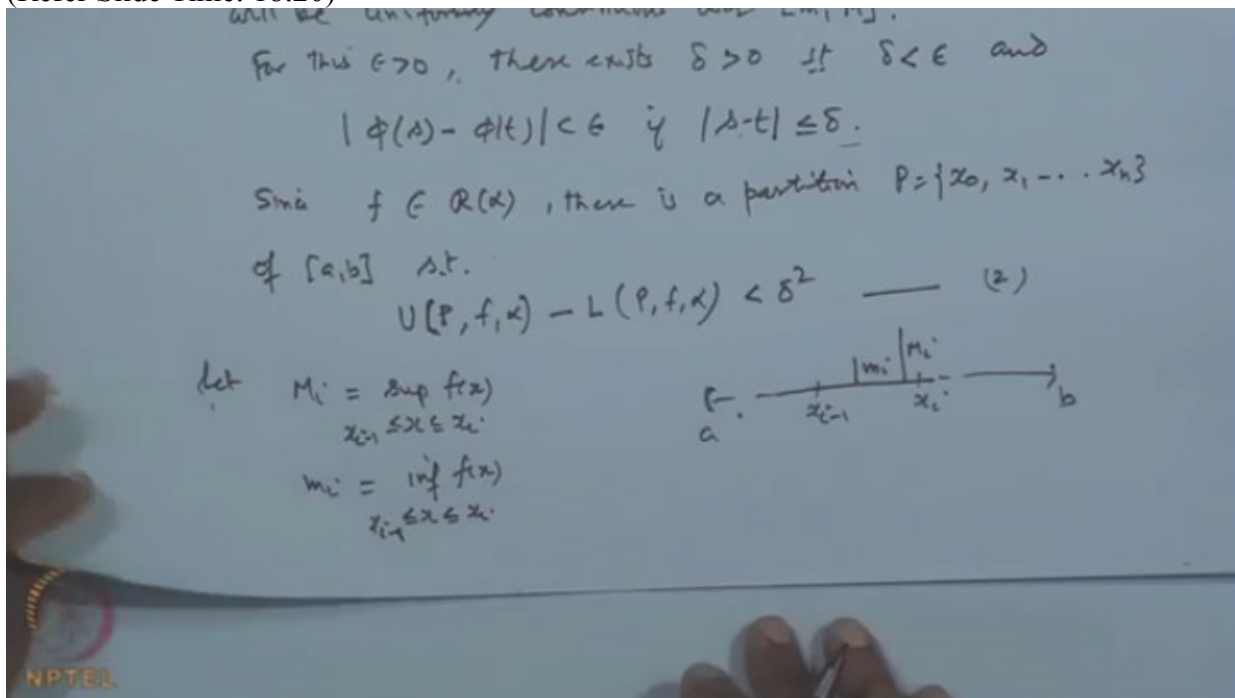

Now suppose I take delta which is greater than epsilon then I can pick up another delta which is smaller than this less than epsilon, so again this image will fall here, so nothing, we are not losing anything, but it will be advantageous while proving the whole theorem, okay.

Now further since  $F$  is given to be an element in  $R(\alpha)$ , so by definition the result a necessary sufficient condition for a function to be a Riemann Steiltjes integral or reviewing the class of this if there exists a some partition, for a given epsilon there exists some partition such that upper sum - lower sum is less than this, so let  $F$  belongs to this then there is a partition, there is a partition say  $P, X_0, X_1, X_2, \dots, X_N$  of  $(A, B)$  such that the upper sum of the function  $F$  with respect to  $\alpha$  - lower sum of the function  $F$  with respect to  $\alpha$  over the same partition is less than say  $\delta^2$ , clear? So this we are getting, so let it be quiz 2. (Refer Slide Time: 17:21)

Now over the sub intervals we have let  $X_{i-1}, X_i$ , this is the sub interval of this partition (A, B), this is the partition (A, B), this is how, now here the function attains this minimum value say  $m_i$  and the maximum value is suppose capital  $M_i$ , so let  $m_i$  and capital  $M_i$ ,  $M_i$  is the supremum of the function  $F(x)$  when  $X$  lies between  $X_{i-1}$  to  $X_i$ , while the  $m_i$ , small  $m_i$  is the infimum value of the function  $F(x)$  when the  $X$  lies between  $X_{i-1}$  to  $X_i$ , clear, let be this one.

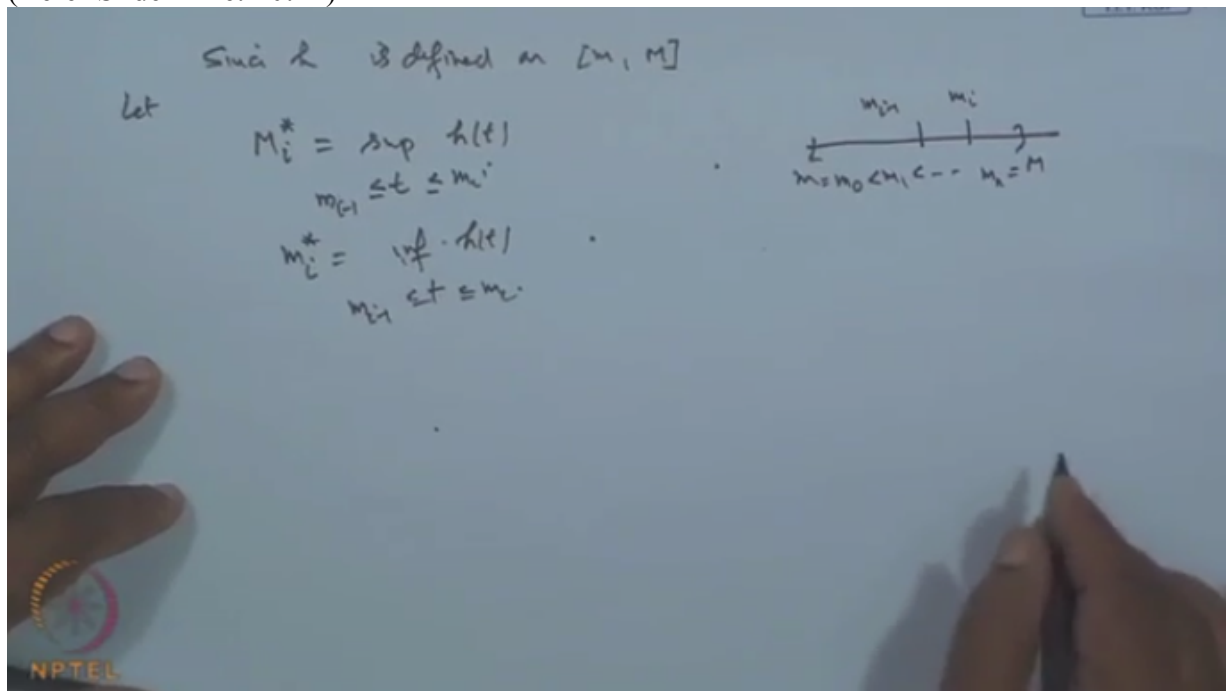

(Refer Slide Time: 18:20)

Now function  $H$  is defined, since  $H$  is defined because what was the result is, that  $H$  is yeah,  $F$  is Riemann integrable,  $F$  is this and  $\phi$  is continuous function,  $\phi$  is continuous on this and  $H$

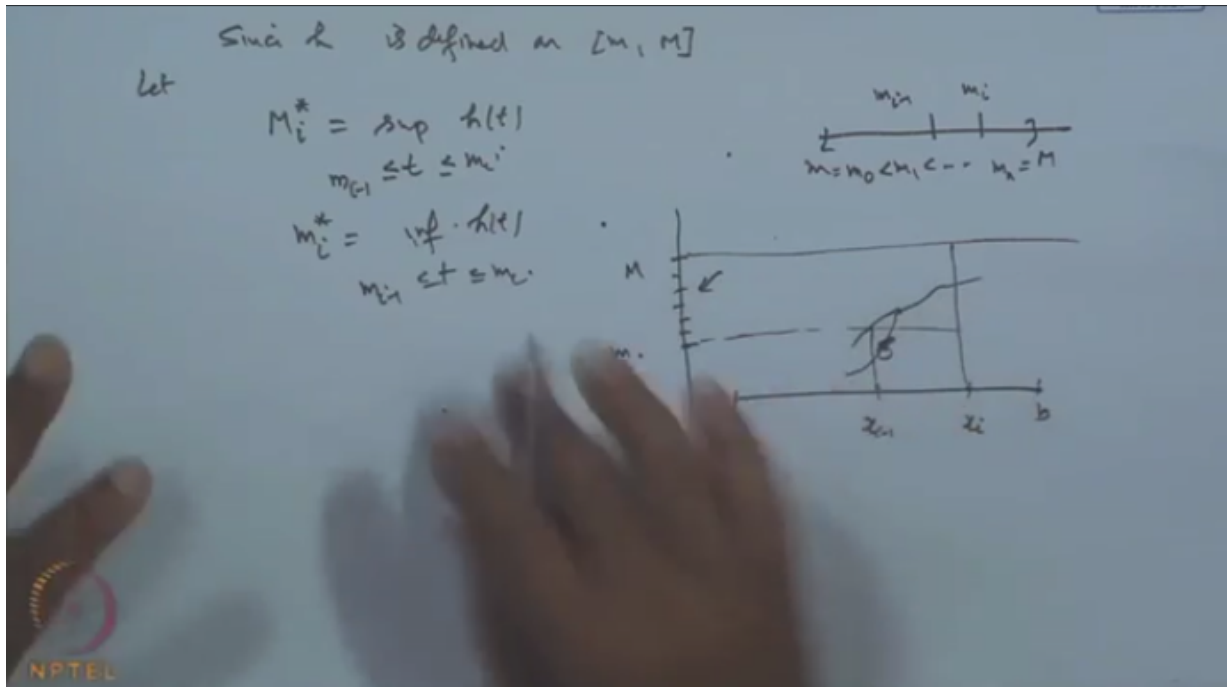

is a function which is basically phi of H F(x), so what are the range of F, H is defined on it, so basically the H is defined on m and capital M let's say, so in this case when you partitioning this (m, M) say m and capital M and suppose I partition it, say M naught less than M1 and so on, say here is MN = N, so if we picked up the say MI-1 and MI, now in this case when you consider the upper and lower bound for the function H, then we say we denote this as let us denote, let MI star is the supremum value of H(t), I am using the T where T lies between MI-1 to MI, and small mi star is the infimum value of H(t) when T lies between MI-1 to MI, is it not? Just I'm taking this one.

(Refer Slide Time: 20:14)

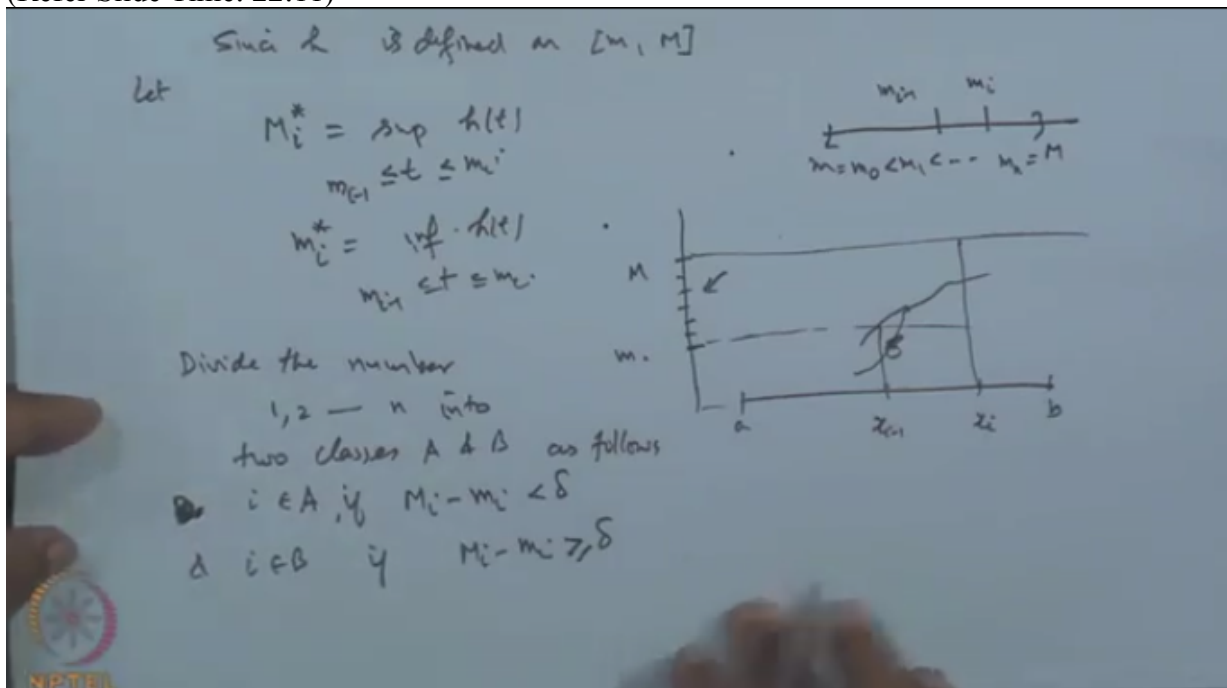

Now, so this is our interval (A, B) here I am taking one say sub interval XI, XI, one over one, and here is say suppose MI's, so this is our say m and here is capital M say this is about, so basically this will be that, okay, that all the functions will be somewhere here, clear, in fact this is wrong, this one, like this, so here is now we are dividing here and then H is defined over this, H is defined on this side, okay.

(Refer Slide Time: 20:58)

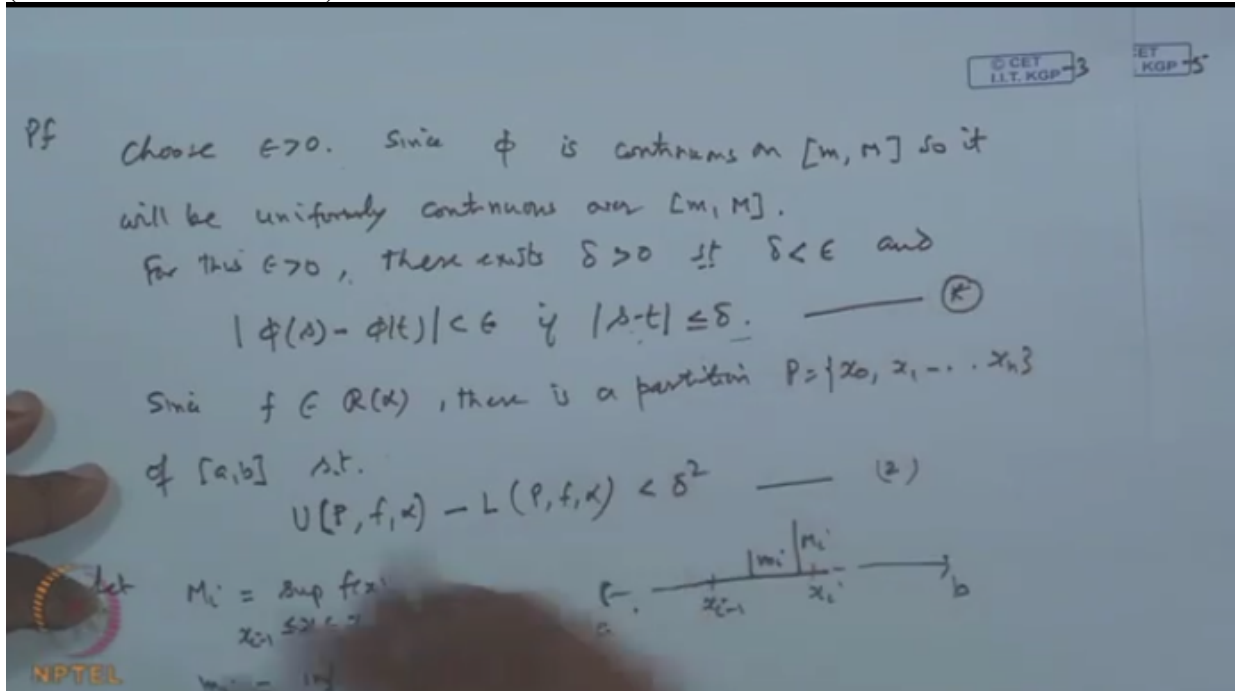

Now let us choose the part, suppose for I divide the number 1, 2, 3, N into two classes, first class is A, two classes A and B as follows, when I belongs to A, for I belongs to A, our choice of delta shows, I belongs to A means that is, if I belongs to A for I belongs to A, if just I belongs to A, if  $M_i - m_i$  is less than delta, and I belongs to B if  $M_i - m_i$  is greater than or equal to that, so this will be like this.

(Refer Slide Time: 22:11)

Now picked up now class one, so for I belongs to A, what is our choice? When I is in A the  $M_i - m_i$  is delta, okay, so in this case what is the  $M_i^* - m_i^*$ , small  $m_i$  star? This will be

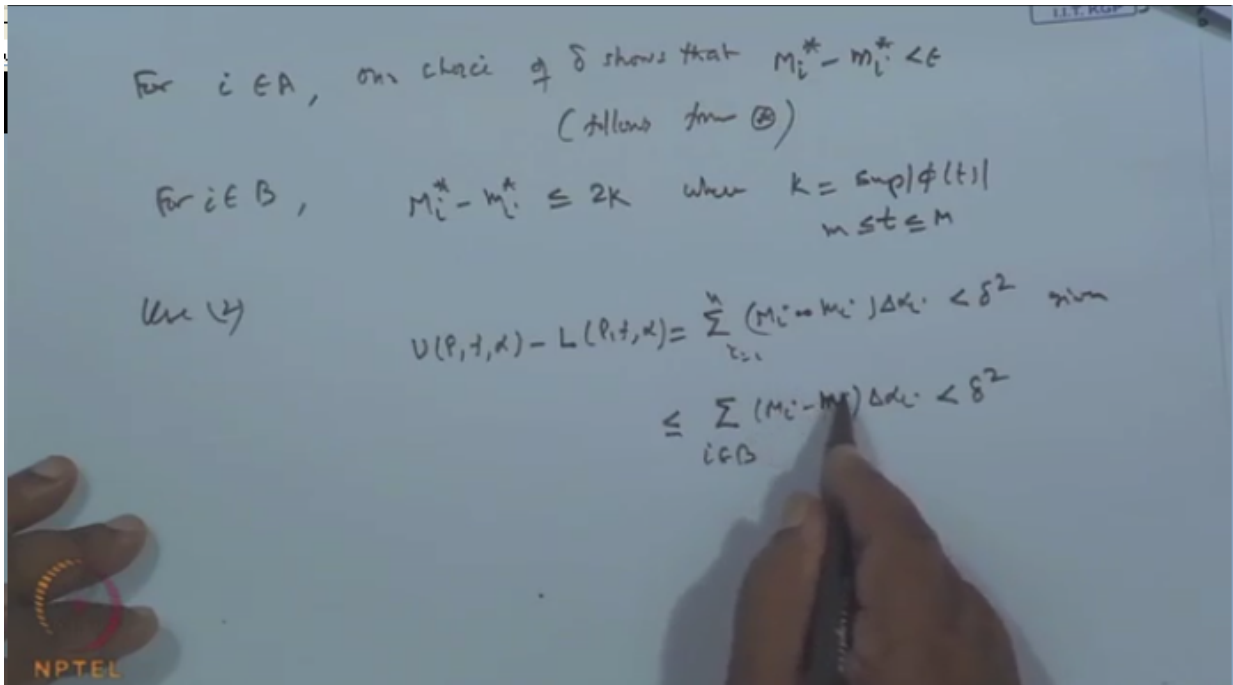

because phi is what? Phi is uniformly continuous, so if I belongs to A it means it satisfy this condition, once it satisfies this condition then because the H or phi is defined on what? On this interval, so is satisfied this condition therefore the difference of this MI - small mi star must be less than epsilon, so since our I belongs to this, so our choice of delta shows that the MI star - small mi star is less than, and this follows from this equation that is the relation, I will say the relation is say X term, okay,  
 (Refer Slide Time: 23:46)

so it follows from the relation star, okay, so nothing.

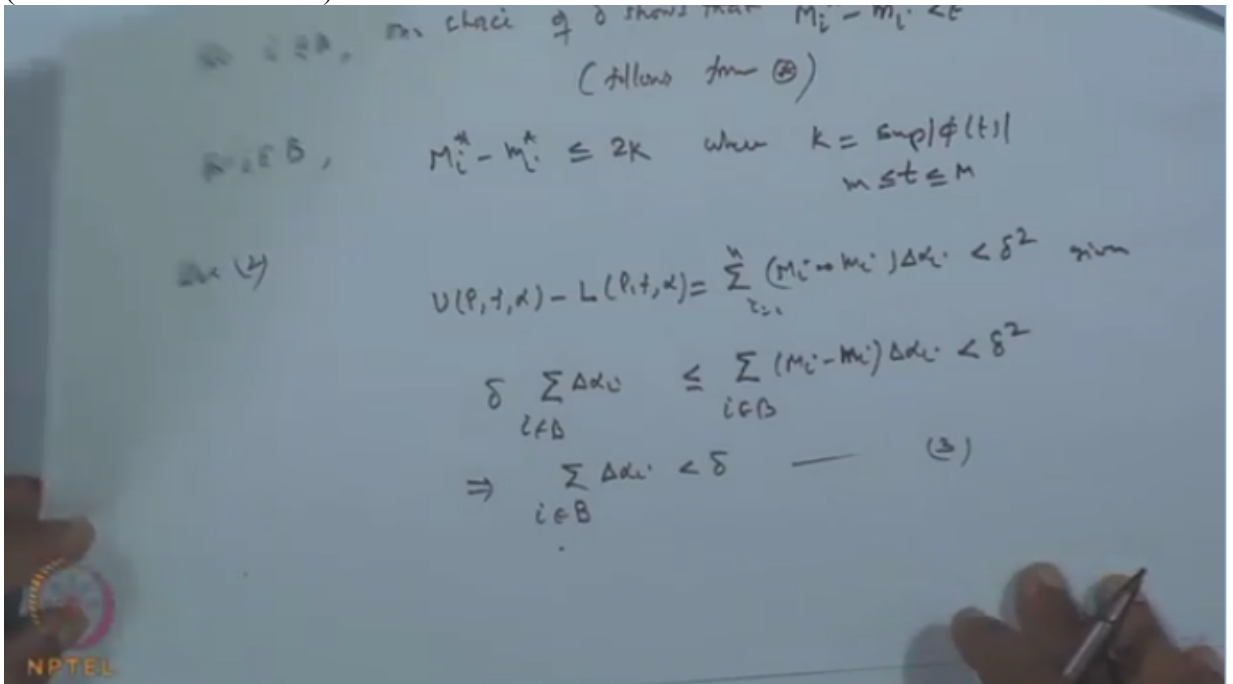

So first thing and if for I belongs to B where this is greater than equal to delta, we have in this interval the MI star - small mi star is less than equal to 2K, where K stands for the supremum value of the phi when T lies between m and capital M, so just supremum value, and since it is greater than, so use the condition 2, where condition 2 is this condition we have taken that is MI - delta square, where is that delta square condition? So this is yeah condition 2, this is our condition 2, this MI, sigma of MI - small mi delta alpha I is less than delta square, so use the condition 2, so use 2, then in that case the U(P, F, alpha) - L(P, F, alpha), this is what? This is sigma MI- small mi delta alpha I, I is 1 to N, but if we take and this is given to be less than delta square, this is given to be delta given.

Now if I take the only for sigma MI-small mi delta alpha I over the set B only, then obviously it will remain less than delta square, because this sum is smaller than this, so it is less than delta square, but this will be greater than equal to what?  
 (Refer Slide Time: 25:59)

Over B this is greater than equal to delta, so it is delta sigma I belongs to B delta alpha I, okay, so what does imply? That's implies that sigma delta alpha I, when I belongs to B is basically less than delta, let it be 3, okay.

(Refer Slide Time: 26:15)

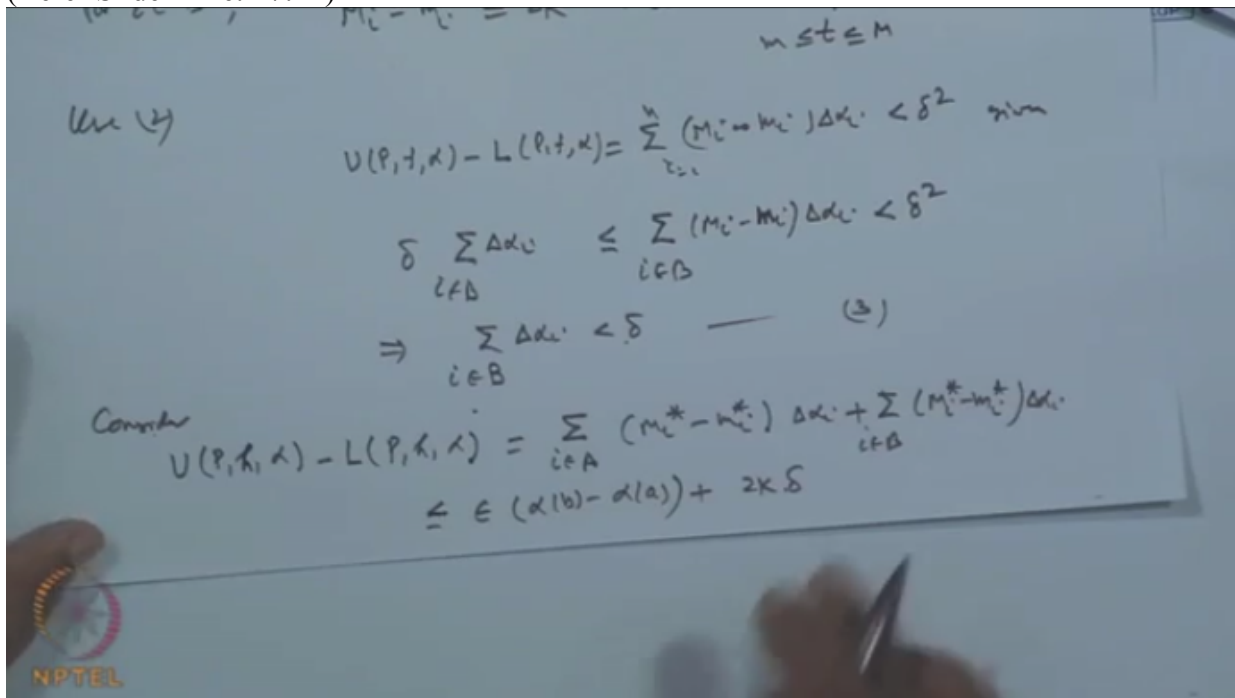

Now consider the partition, now consider the upper sum of the function H with respect to alpha - the lower sum of H with respect to alpha, and this we can divide in two parts when I belongs to A, MI star - small mi star delta alpha I + when I belongs to B MI star - small mi star delta alpha I, okay.

Now see this will be MI star -, when I belongs to A we have already justified this is less than epsilon, so this is basically less than epsilon and then delta alpha I will be less than, sigma of delta alpha I is nothing but less than alpha B - alpha A, so we get this part, okay.

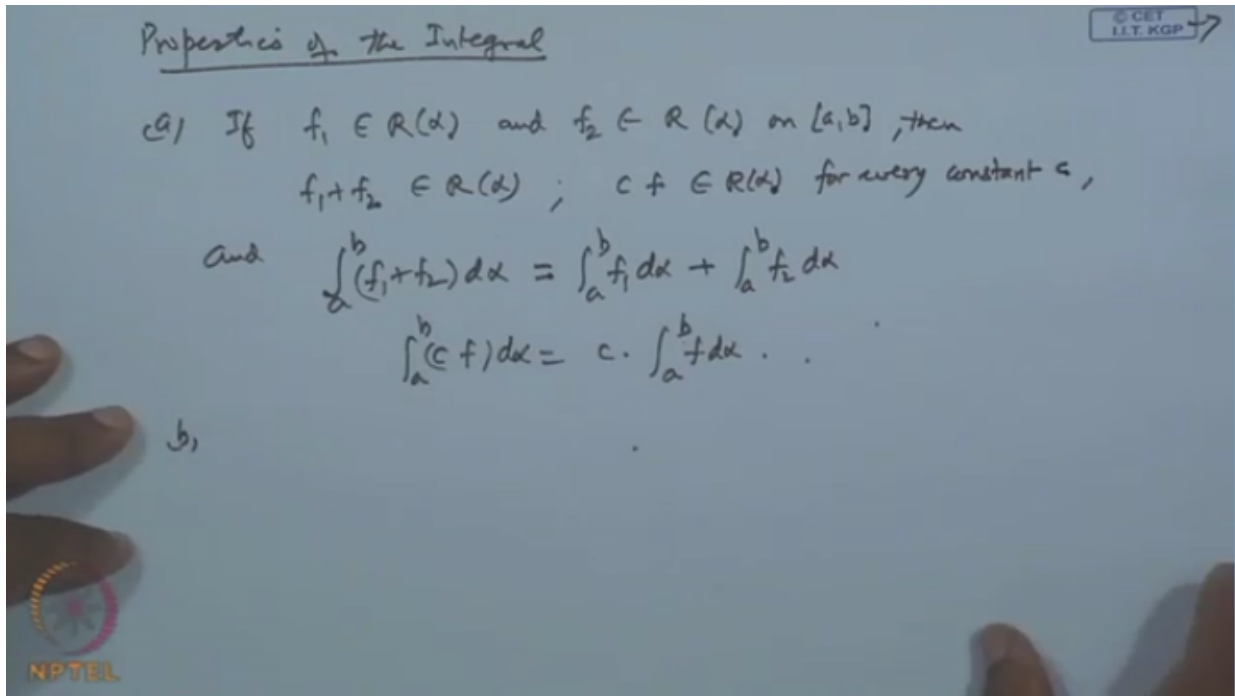

The second portion is this entire thing is less than 2K, because this is 2K so it is less than 2K and then over B the sigma is less than epsilon, sigma is less than this delta alpha I when you choose what is, sorry delta, sigma I is less than delta so it is delta,  
(Refer Slide Time: 27:41)

so once it's delta but delta is less than epsilon this is our choice in the very beginning, beginning of this we have taken delta to be less than epsilon, so we can choose the delta outside so we get the P, H, alpha - L(P, H, alpha) is less than equal to epsilon outside, what you are getting is alpha B - alpha A + 2K, but epsilon is arbitrary, since epsilon is arbitrary, so this shows that satisfies the necessary sufficient condition of that theorem, therefore H must be in R(alpha), some few properties of the Riemann Steiltjes integrals, we will list the proof, property and proof, one or two will be good enough.

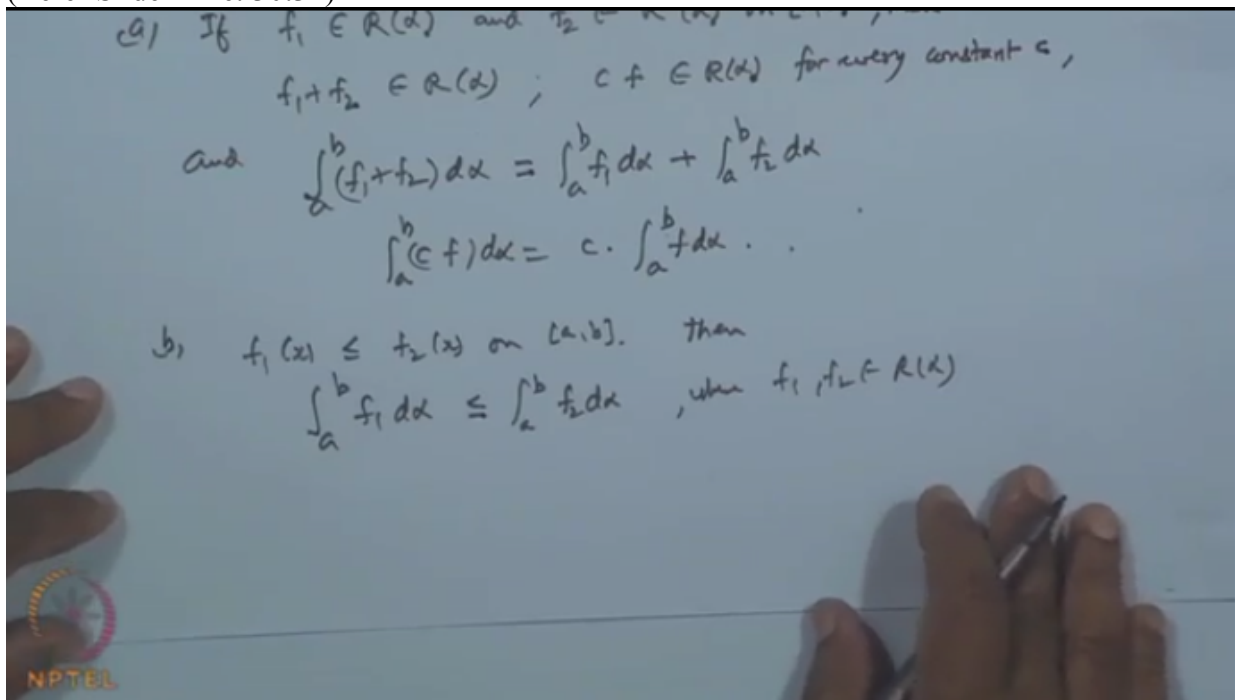

Now if F1 is a Riemann Steiltjes integral with respect to alpha, F2 is a Riemann Steiltjes integral with respect to alpha on the closed interval (A, B), then the sum F1 + F2 will also be a Riemann Steiltjes integral with respect to alpha, and CF will also be a Riemann Steiltjes integral with respect to alpha for every constant C, and the integral A to B, F1+F2 D alpha the Riemann Steiltjes integral, the sum of it will be some of the integrals F1 D alpha + A to B, F2 D alpha and C times FD alpha is C multiplied by A B to be FD alpha, so this is the first result.

(Refer Slide Time: 29:55)

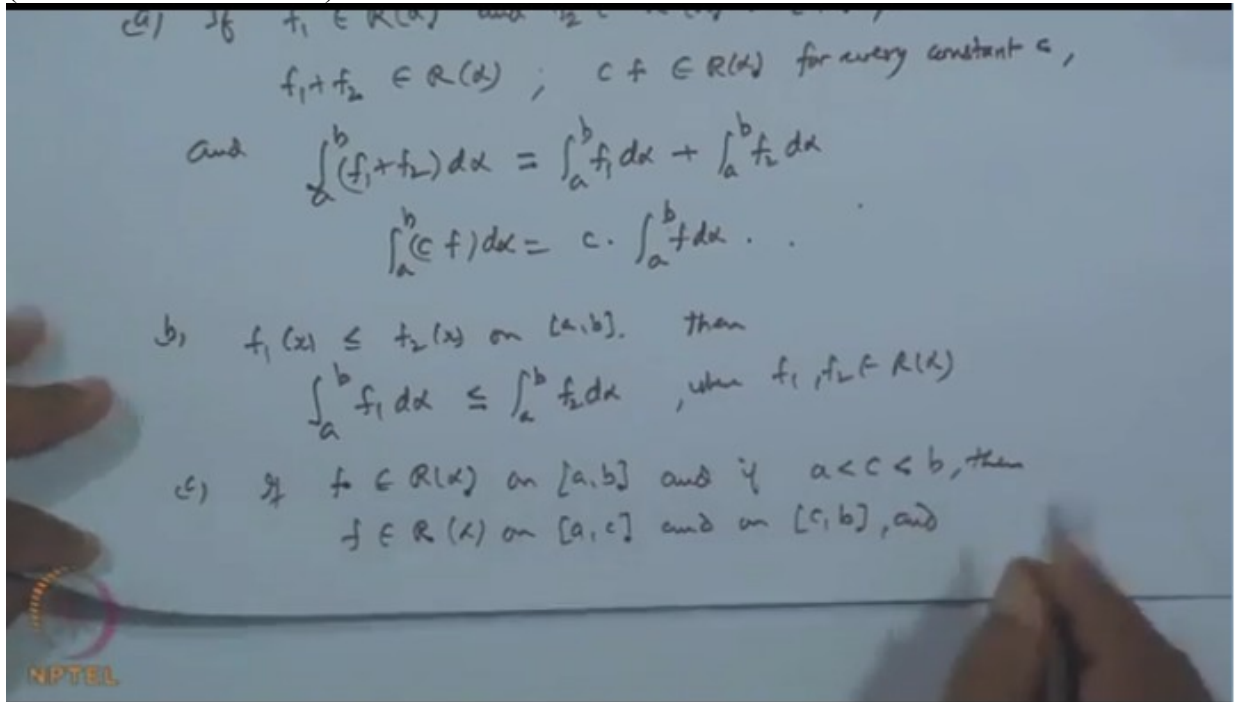

Second result says if suppose  $F_1$  and  $F_2$  are the two Riemann Steiltjes integral, if  $F_1$  and  $F_2$  are the two functions such that  $F_1(x)$  is less than equal to  $F_2(x)$  on the closed interval  $(A, B)$  and they are also Riemann Steiltjes integral and then integral  $A$  to  $B$   $F_1 D \alpha$  is less than equal to integral  $A$  to  $B$   $F_2 D \alpha$ , of course where  $F_1$  and  $F_2$  both are in  $\alpha$ ,  $R(\alpha)$  okay.

(Refer Slide Time: 30:32)

Third is, third property is if  $F$  is, if  $F$  belongs to  $R(\alpha)$  that a Riemann Steiltjes integral on the closed interval  $(A, B)$  and if  $A$  is less than  $C$ , less than  $B$ , then  $F$  is Riemann Steiltjes integral on the closed interval  $(A, C)$  as well as on  $(C, B)$  means if we divide that  $(A, B)$  into

two parts AC to CB then over each subinterval function F remain Riemann Steiltjes integral with respect to same alpha and the value of the integral will be the sum of this two,  
 (Refer Slide Time: 31:17)

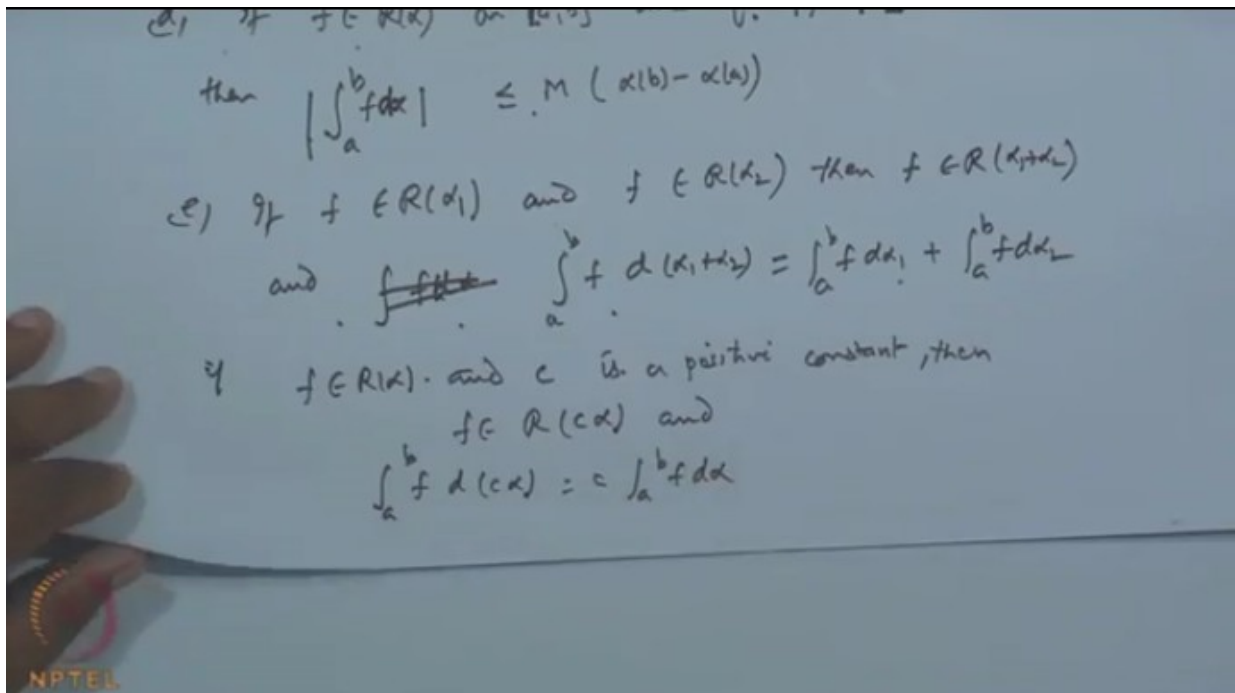

and integral A to B FD alpha is the same as A to C FD alpha + C to B FD alpha.

Fourth property is if F is a Riemann Steiltjes integral with respect to alpha on the closed interval (A, B), and if the function F(x) is bounded by M on the closed interval (A, B) then integral A to B FDX, FD alpha into FD alpha modulus of this, modulus of this is less than equal to M times alpha B - alpha A, okay, modulus of this D alpha. Then E property if F is Riemann Steiltjes integral with respect to the monotonic function alpha 1, and F is a Riemann Steiltjes integral with respect to monotonic function of alpha means F is Riemann Steiltjes integral with respect to the two monotonic functions alpha 1 and alpha 2 respectively,  
 (Refer Slide Time: 32:48)

than  $F$  will remain Riemann Steiltjes integral with respect to the sum of these  $\alpha_1 + \alpha_2$ , because if that  $\alpha_1, \alpha_2$  are monotonic increasing the summation will also be monitoring increasing, if they are monitoring decreasing they will also be monitoring decreasing, and hence the integral of  $F$  with respect to  $\alpha_1 + \alpha_2$  over  $A$  to  $B$  is the same as  $\int_A^B F d\alpha_1 + \int_A^B F d\alpha_2$ .

And if  $F$  is Riemann Steiltjes integral with respect to  $\alpha$ , and  $C$  is a positive constant, then  $F$  is Riemann Steiltjes integral with respect to  $C\alpha$ , and  $\int_A^B F d(C\alpha) = C \int_A^B F d\alpha$ ,

the proof of these results property follows by using the difficult property is also which we just mentioned, if  $F$  is in  $R(\alpha)$  and  $G$  is also in  $R(\alpha)$  on the interval  $(A, B)$ , then the product of this is in  $R(\alpha)$ , then second part is if  $\text{mod } F$  belongs to  $R(\alpha)$  and modulus of integral  $A$  to  $B$   $F d\alpha$  is less than equal to integral  $A$  to  $B$   $\text{mod } F d\alpha$  and less than equal to  $B$ , the proof is which.
