IPP Branch & Bound Method

So, in the last class we started the integer linear programming problem where the decision variables are the integers and they take the positive values. We have done the Gomory's cutting plane method. If you remember, we have told in the last class that I P P problems can be solved by two ways; one is Gomorian cutting plane method, where whenever you have one variable decision. Variable in the basis whose value is non integer. You are adding one constant and you are adding one Gomorian slack variable to remove that particular decision variable from the basis.

So, that we have seen in the last class. Today, in this class we will discuss the branch and bound method for solving the I P P. It is similar to this earlier one there is a basic difference in branch and bound method in branch and bound method. At first, we try to find the solution and we check that which variables in the basis has non integer values from there we try to find out the upper bound and lower bound of the problem and then we divide the original problem into two sub problems by adding two more constants, using the lower bound and using the upper bound of the problem. So, that we are doing it. So, let us see what the branch and bound method uses in branch and bound method.

(Refer Slide Time: 02:06)

Suppose, you have a problem maximize z equal $c x$ subject to $A x$ equals b x_j greater than equals 0 and this is integers. Now x_j , if x_j is not an integer, in that case I can write down x_j equals w_j plus f_j where w_j is the integer part and f_j is the fractional part where f_j lies between 0 and 1 ; obviously. So, you have the problem original, problem maximized. z equals $c x$ subject to $a x$ equals b x_j greater than equals 0 . If x_j is not an integer, in that case we are writing x_j equals w_j plus f_j form, where w_j is integer part of the variable and f_j which lies between 0 and 1 is the fractional part of the problem. If you take any, it will must satisfy any one of these two conditions. I think it is fine, x_j less than equals w_j or x_j greater than equals w_j plus 1 , because the bound it will be either exactly less than equals w_j or it will be plus 1 since your f_j is the fractional part whose value lies between 0 and 1 . So, for any feasible integer solution of the problem, it must satisfy any one of these two constants x_j less than equals w_j or x_j greater than equals w_j .

So, basically what we are doing; since your x_j is less than equals w_j or x_j greater than equals w_j . So, we are dividing this original problem into two sub problems in one sub problem. We will include the new constant x_j less than equals w_j and in the another sub problem. We will include the other inequality condition x_j greater than equals w_j plus 1 or in other sense I can reformulate.

(Refer Slide Time: 04:21)

We formulate two subproblems:

SP1	SP2
$\text{Max } z = cx$	$\text{Max } z = cx$
$\text{s.t. } Ax = b$	$\text{s.t. } Ax = b$
$x_j \geq w_j + 1 \text{ and integer}$	$0 \leq x_j \leq w_j \text{ and integer}$

The solution having larger objective function value will be the required optimal solution.

If any subproblem has non-integer variable, then it should be partitioned further.

two sub problems like this one; I am telling SP 1, where we are telling maximized z equals $c x$ subject to $A x$ equals b x_j greater than equals w_j plus 1 and integer.

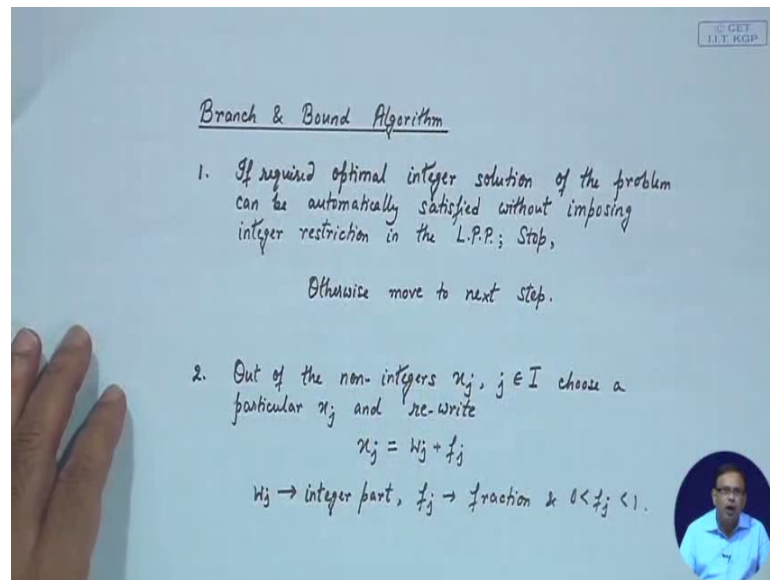

So, one condition we are writing here x_j greater than equals w_j plus 1 and obviously, all x_j will be integer and the sub problem 2 SP 2, which are denoting as SP 2. This we are writing as maximized z equals $c x$ subject to $A x$ equals b along with 0 less than equals x_j less than equals w_j and x_j 's are integer. So, whenever I am getting the lower bound and the upper bound of a non integer variable in the basis from there I am making two conditions x_j less than equals w_j and x_j greater than equals w_j plus 1 and from there we are formulating two sub problems like this SP 1 and SP 2.

Now, the solution having larger objective function value will be the required optimal solution. So, there are some possibilities one case is both the problems SP 1 and SP 2 has optimal solution and they satisfy the feasibility condition that is you are getting the integer solution for both the problems SP 1 and SP 2. In that situation the solution having larger objective function value will be the required optimal solution. Now, if any sub problem is has non integer variable. If any of these two sub problem has non integer variable, then again it should be partitioned further.

That means you have the original problem SP. Once you have the original problem and for this particular problem, if the optimal solution contains non integer values for the basis variable divide it into two sub problems SP 1 and SP 2. One will contain the lower

bound constant, the other one will contain the upper bound constant, then again if required you can divide these and like this way it will continue until you are obtaining, your required solution. So, basic idea is this thing.

(Refer Slide Time: 07:00)

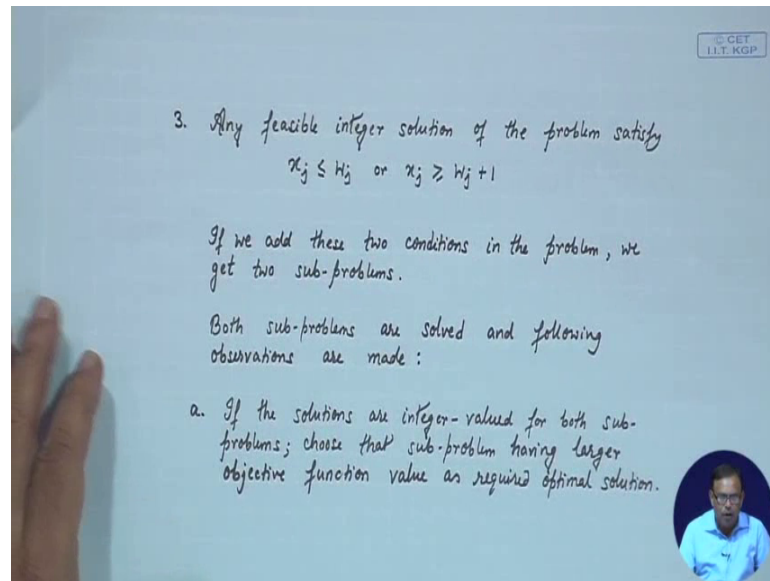

The image shows a whiteboard with handwritten text. At the top right, there is a small logo for 'CET I.I.T. KGP'. The title 'Branch & Bound Algorithm' is underlined. Below it, there are two numbered steps. Step 1 describes a condition for stopping the algorithm. Step 2 describes how to branch on a non-integer variable. A small circular inset in the bottom right corner shows a person's face.

Branch & Bound Algorithm

1. If required optimal integer solution of the problem can be automatically satisfied without imposing integer restriction in the L.P.P.; Stop, Otherwise move to next step.
2. Out of the non-integers $x_j, j \in I$ choose a particular x_j and re-write
$$x_j = w_j + f_j$$
$$w_j \rightarrow \text{integer part, } f_j \rightarrow \text{fraction \& } 0 < f_j < 1.$$

So, this in terms of the algorithm we can write it like this branch and bound algorithm; if required optimal integer solution of the problem can be automatically satisfied without imposing the integer restriction in the LPP in that case stop; that means, without imposing integer restriction. If I solve the problem and if I obtain that the solution is optimal and providing me the integer solution in that case, that solution will be the optimal 1 and I will stop otherwise I will go to the next stop, whatever we have told out of non integer x_j s_j belongs to I 1 to n or whatever it may be choose one particular x_j and rewrite it, in the form of x_j equals w_j plus f_j . Where w_j is the integer part and f_j is the fractional part of this x_j and obviously, your f_j lies between 0 and 1. So, in that case after that in step.

I.I.T. KGP

3. Any feasible integer solution of the problem satisfy
 $x_j \leq w_j$ or $x_j \geq w_j + 1$

If we add these two conditions in the problem, we get two sub-problems.

Both sub-problems are solved and following observations are made:

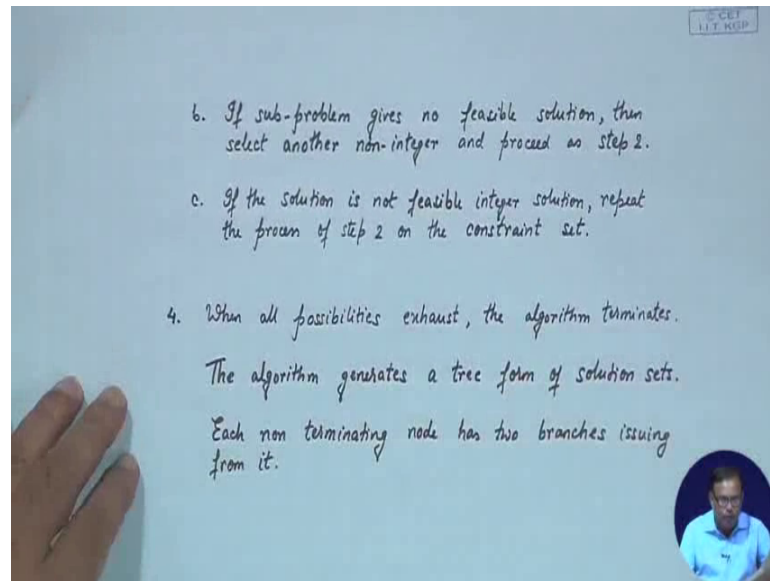

a. If the solutions are integer-valued for both sub-problems; choose that sub-problem having larger objective function value as required optimal solution.

(A small circular inset video shows a person speaking in the bottom right corner of the slide.)

Three, any feasible integer solution of the problem which will satisfies will satisfy either x_j less than equals w_j or x_j greater than equals $w_j + 1$. So, if we add these two conditions in the problem. We will obtain two sub problems, both sub problems. You have to solve and following observations can be made both sub problems whenever we are solving. The observations can be made if the solutions are integer valued for both sub problems. If the solutions are integer valued for both sub problem choose that sub problem having larger objective function value as required optimal solution.

So, please note this one, if the solutions are integer valued for both sub problems choose the sub problem having larger objective, function value as required optimal solution.

(Refer Slide Time: 09:24)

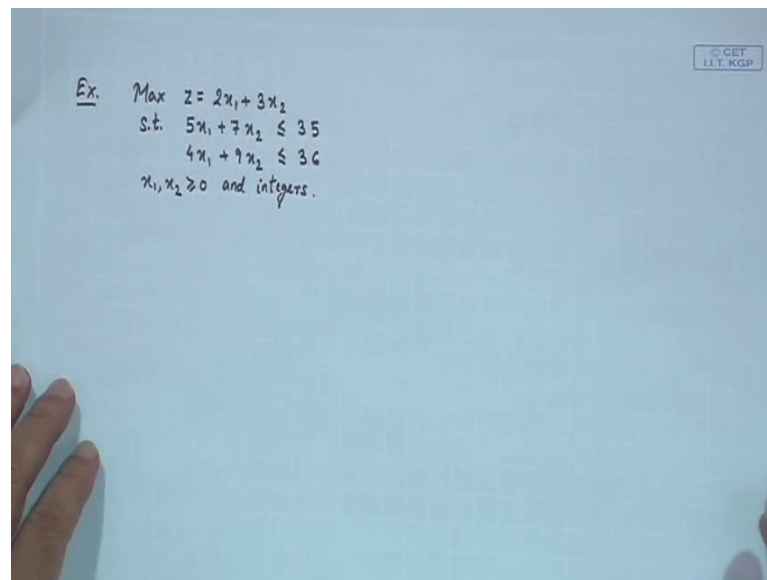

So, this is one case which may arise the next case will be if the sub problem gives no feasible solution then select another non integer decision variable in the basis another non integer variable and proceed as step 2, whatever we told means if the non integer variable which you have taken after that you are dividing it into 2 sub problems and if both the sub problems having no feasible solution then you have to choose another non integer variable and repeat the process 2 as we are saying as in steps 2.

If number c, if the solution is not feasible integer solution repeat the process of step 2 on the constants rate; that means, again follow the same process sub divide the problem when all possibilities exhausted the algorithm will terminate; that means, it has no solution. So, this algorithm generates a tree form of solution set. Please note this one as I have shown earlier, I will, it will have a root from the root, it will have some branches, each branch may have sub branches like this way it will continue.

So, this algorithm generates a tree form of the solution set each non terminating node will have two branches which will be issued from here; that means; from root there will be always two branches. Now, let us take one example and let us see how the branch and bound method exactly works for this particular problem let us take this problem;

(Refer Slide Time: 11:18)

A photograph of a whiteboard with handwritten mathematical text. The text is written in black ink and includes a maximization problem with constraints. In the top right corner of the whiteboard, there is a small rectangular stamp that reads 'S. CET' and 'I.I.T. KGP'.

$$\begin{aligned} \text{Ex. Max } z &= 2x_1 + 3x_2 \\ \text{s.t. } 5x_1 + 7x_2 &\leq 35 \\ 4x_1 + 9x_2 &\leq 36 \\ x_1, x_2 &\geq 0 \text{ and integers.} \end{aligned}$$

Maximize z equals $2x_1$ plus $3x_2$ subject to $5x_1$ plus $7x_2$ less than equals 35 $4x_1$ plus $9x_2$ less than equals 36 and x_1, x_2 greater than equals 0 and both are integer.

Now, for this problem I can find the solution in two ways; one is, I can use the normal simplex method I can add the slack variables on it and if I wish then I can write down the initial simplex method, initial simplex table and from there I can go on iterating until I am obtaining the solution instead of doing the simplex algorithm. Since it is a problem of 2 variables only we will use the graphical method with respect to this one. So, you see these two problems, these two constants for the graphical method. What I have to do I have to draw the line for $5x_1$ plus $7x_2$ equals 35 and $4x_1$ plus $9x_2$ equals 36 and x_1, x_2 greater than equals 0 and they are integers.

(Refer Slide Time: 12:38)

So, please see from here that, in this line represents $5x_1 + 7x_2 \leq 35$ that is equals 35. It crosses the 0.7 on the x axis and 5 on the y axis whereas, $4x_1 + 9x_2 \leq 36$. This will meet the point at 9 on the x axis and 4 on the y axis. So, you are getting the second line $4x_1 + 9x_2 \leq 36$. Since they are both less than equal, direction will be for both of them will be this 1.

So, and the region will be this shaded region bounded by this two lines and the coordinate axis that is x axis and y axis. So, from the graphical solution it is quite obvious these are the extreme points and if you calculate, you will obtain the maximum value of these at this point, that is 16 by 63 by 17 and 40 by 17. Therefore, after graphical solution of the original problem, what we are obtaining x_1 equals 63 by 17 x_2 star is 40 by 17 and z star equals 246 by 17.

So, using this graphical method, what happens your solution is like this x_1 star equals 63 by 17 your x_2 start equals 40 by 17 and your z star or z max is becoming 246 by 17, although this is the optimal the solution which you obtained, but this solution is not feasible, since both of them x_1 and x_2 are non integer now. So, since both x_1 and x_2 are non integer. So, I have to choose anyone of these two.

So, we are choosing say choose x_1 , we are choosing x_1 , because x_1 has the largest fractional value largest fractional value. So, what is the upper bound of z initial upper bound of z is initial upper bound of z. This is equals to 246 by 17, which is

approximately if I make this, will be 14.0. This now, similarly the bound of x_1 initial or bound of x_1 is from 3 to 4. From here your x_1 is 3.0 something.

So, x_1 can take x_1 , not x_2 , but the bound of x_1 . If I have to write bound of x_1 is 3 and 4. This I got from this value 63 by 17. This is 3.0 something. So, lower bound of x_1 is 3 and upper bound of x_1 is 4. Similarly, lower bound of x_2 will be 2 and in the same case this is 34. So, lower bound of x_2 is 2 and upper bound of x_2 is 3.

So, we are finding for the integer, for the variables which contains non integer values. What is the lower bound and what is the upper bound; So, for x_1 lower bound is 3 and upper bound is 4. So, from here now, I can formulate two problems in one case your x_1 will lie in between 0 and 3 in other case your x_1 will be greater than equals 4. So, now, this original problem, say this was your S P what we denote this thing as S P.

So, your S P this problem is divided into two sub problems which we are denoting as SP 1 S P 2.

(Refer Slide Time: 17:05)

The image shows handwritten mathematical notes on a blue background. It is divided into two main sections, SP1 and SP2, each with its own objective function, constraints, and optimal solution. Below SP2, there is a diagram showing SP2 branching into SP3 and SP4.

SP1

$$\text{Max. } Z = 2x_1 + 3x_2$$

$$\text{s.t. } 5x_1 + 7x_2 \leq 35$$

$$4x_1 + 9x_2 \leq 36$$

$$0 \leq x_1 \leq 3,$$

$$x_1, x_2 \geq 0, \text{ int.}$$

$$x_1^* = 3, x_2^* = \frac{8}{3}, Z^* = 14.$$

SP2

$$\text{Max. } Z = 2x_1 + 3x_2$$

$$\text{s.t. } 5x_1 + 7x_2 \leq 35$$

$$4x_1 + 9x_2 \leq 36$$

$$x_1 \geq 4, x_2 \geq 0, \text{ int.}$$

$$x_1^* = 4, x_2^* = \frac{15}{7},$$

$$Z^* = \frac{101}{7}$$

Diagram: SP2 branches into SP3 and SP4.

Your SP 1 will be maximized z equals $2x_1 + 3x_2$ subject to $5x_1 + 7x_2$ less than equals 35, $4x_1 + 9x_2$ less than equals 36 and 0 less than equals x_1 less than equals 3. This extra condition now we are adding compared to the earlier problem. If you see and this we are adding since the lower bound is 3 and upper bound is 4 for the variable x_1 .

So, x_1 lies between 0 to 3 $x_1 \times x_2$ greater than equals 0 and; obviously, they are integers, and similarly, yours problem 2 will be SP 2 will be maximized z equals $2 \times x_1$ plus $3 \times x_2$ subject to $5 \times x_1$ plus $7 \times x_2$ less than equals 35. First two constants will remain same, that is second one will be $4 \times x_1$ plus $9 \times x_2$ less than equals 36 x_1 greater than equals $4 \times x_2$ greater than equals 0 and both the variables should be integers.

So, now what you have to do. So, you see the original problem I am dividing into 2 sub problems and how we are dividing it. We are dividing it by the basis of the value of the lower bound and upper bound of the non integer variable. So, in the basis or in the solution if I have the variables, whose values are non integer from there, I will choose the variable which has more or larger fractional value as in this particular example we have chosen x_1 since x_1 has the larger fractional value, then we are finding out the lower bound and upper bound of x_1 , which is 3 and 4 respectively for this particular problem.

Then we are creating two sub problems. Now, these two sub problems again can be solved by graphical method purposefully, we have chosen it.

(Refer Slide Time: 19:38)

So, for the sub first sub problem if you choose then your problem will be like this your 1 is $4 \times x_1$ plus $9 \times x_2$ equals 36 another line $5 \times x_1$ plus $7 \times x_2$ equals 35 and x_1 less than equals 3, this is the bound. So, this is on this direction.

So, your feasible region is the shaded 1, and if you calculate you will find at the 0.38 by 3, you are obtaining the solution. So, therefore, your solution is for the first problem x_1 equals 3 x_2 is 8 by 3 and z star equals 14. So, please note this one that for this problem your x_1 star, this is equals to 3 your x_2 star is 8 by 3 for the first problem SP 1 and your z star is 14 8 by 3 and your z star is equals to 14, whatever you are getting now, similarly for the second problem also graphically I can find out the solution my solution set will be like this.

This is the line again $5x_1 + 7x_2$ and this is the line for $4x_1 + 9x_2$ less than equals 36 and for this case your x_1 is greater than equals 4. If you try to find out the solution you will get it at this point the maximum value. So, for this case your solution is x_1 is 4 x_2 is 15 by 7 z star. You will obtain 10 1 by 7. So, you are getting this two. So, for this case your solution is x_1 star equals 4 x_2 star. This is equals 15 by 7 and z star equals 10 1 by 7

So, if you see in this case for this problem I obtain two solutions,, but in both cases your x_2 is having non integer value and your, for the problem S P, two basically. You have more optimum value of the objective function. So, as we have told since in both the cases. I am getting non integer solution again, I have to sub divide the problem, Now, since I have to sub divide the problem; that means, now your SP 2 has to be sub divided into S P 3 and S P 4, this 2, here, if you see your x_2 is the non integer value the lower bound and upper bound from here. It is very clear lower bound of x_2 will be 2 and upper bound of x_2 will be 3.

So, in the original problem, from the original problem means I want to say on this particular problem. Now, I will impose one more condition. Now, what will be the condition? So, SP 2 I am dividing. So, these constants will remain as it is along with this. I will add one more constant for x_2 for the lower bound and for the upper bound lower bound is 2 and upper bound is 3 for this case. So, your I can write down your S P 3 as.

(Refer Slide Time: 23:36)

The image shows a whiteboard with two linear programming problems, SP3 and SP4, written in blue ink. In the top right corner, there is a small logo for 'CET IIT, KGP'.
Problem SP3 is on the left and reads:
Max $Z = 2x_1 + 3x_2$
s.t. $5x_1 + 7x_2 \leq 35$
 $4x_1 + 9x_2 \leq 36$
 ~~$0 \leq x_1 \leq 4$~~
 $0 \leq x_1 \leq 4$
 $0 \leq x_2 \leq 2$
int.
Problem SP4 is on the right and reads:
Max $Z = 2x_1 + 3x_2$
s.t. $5x_1 + 7x_2 \leq 35$
 $4x_1 + 9x_2 \leq 36$
 $0 \leq x_1 \leq 4$
 $x_2 \geq 3$ int.

Maximized z equals $2x_1 + 3x_2$ subject to $5x_1 + 7x_2 \leq 35$, $4x_1 + 9x_2 \leq 36$, your condition was x_1 already greater than equals 4; that means, one condition will be x_1 lies between 0 to 4 less than x_1 less than equals 4. It cannot be this one and the one more condition.

Now, I will add that is $0 \leq x_2 \leq 2$. So, whatever was there along with this your x_1 must lie in between. Now, 0 to 4, at 4 we obtained the solution. So, x_2 lower bound is 2, upper bound is 3, for that reason here I have added x_1, x_2 lies between 0 to 2 and x_1, x_2 should be integer. Similarly, your S P 4, this will become. Now, this is S P 4. So, S P 4 will be maximized, z equals $2x_1 + 3x_2$ subject to $5x_1 + 7x_2 \leq 35$, $4x_1 + 9x_2 \leq 36$, your this condition is there, that is x_1 lies between 0 to 4 and your upper bound, if you see here upper bound is 3. Since it is fractional part and upper bound is 3.

So, therefore, I have to add one more thing $x_2 \geq 3$ and these are the all are integer values. So, now, as we have done earlier graphically I will solve this problem. So, I am just seeing here that this is the line $5x_1 + 7x_2 = 35$. This is the line $4x_1 + 9x_2 = 36$ and this is the line $x_1 \leq 4$, that is this thing and what was the other $x_2 \leq 2$ was the second one. If you would see x_2 lies between 0 to 2. So, that your solution space will be

this one, this shaded region is the feasible region and if you calculate you will find at the point $(4, 2)$ we are getting the maximum value.

So, your solution in this case will be $x_1 = 4$, $x_2 = 2$ and $z^* = 4$. So, for this problem your solution then becomes $x_1^* = 4$, $x_2^* = 2$ and your $z^* = 14$ from the problem. Similarly, now I can find the solution of this 1 for this case if you find your $5x_1 + 7x_2 = 35$, your $4x_1 + 9x_2 = 36$, $x_1 \leq 4$, you see the directions for this also direction is this for this; that means, this area, but x_2 is greater than $= 3$; that means, this portion upper portion.

So, therefore, they are not intersecting anywhere or in other sense we can tell that this problem has no feasible solution and z^* does not exist over here for this problem graphically it is quite clear, just see there will be no intersecting area among these 5 coordinate axis and this 4 lines. So, for this case we can write down no feasible solution for this problem no feasible solution, but for this case you see we obtained the optimal solution and they are satisfying the integer restriction also.

Therefore the solution of the original problem will be this $x_1 = 4$, $x_2 = 3$ and $z^* = 14$. So, the original solution for this problem will be the solution of $s = 3$, which is $x_1^* = 4$, $x_2^* = 2$ and $z^* = 3$. So, I hope it is clear that how using branch and bound method. We can solve one integer programming problem where basically, whenever in a solution you are obtaining non integer value for a decision variable you are breaking the problem into two sub problems in one sub problem. You are using adding one more constant for the lower bound of the non integer variable in another sub problem. You are breaking it into, you are adding the constant of upper bound, and by this way again you are solving the problem and you are repeating the process until you are obtaining the desired solution.
