

**Constrained and Unconstrained Optimization**  
**Prof. Debjani Chakraborty**  
**Department of Mathematics**  
**Indian Institute of Technology, Kharagpur**

**Lecture – 52**  
**Constrained Optimization**

Now, today again, I am dealing with the multi variable constraint optimization problem. I explained one of the methodology that was a direct method and to solve the constraint non-linear programming problem.

(Refer Slide Time: 00:37)

**Characteristic of a constrained problem**

Direct Methods	Indirect Methods
Random search methods	Transformation of variables technique
Heuristic search methods	Sequential unconstrained minimization techniques
Complex method	Interior penalty function method
Objective and constraint approximation methods	Exterior penalty function method
Sequential linear programming method	Augmented Lagrange multiplier method
Sequential quadratic programming method	
Methods of feasible directions	
Zoutendijk's method	
Rosen's gradient projection method	
Generalized reduced gradient method	

 IIT KHARAGPUR  NPTEL ONLINE CERTIFICATION COURSES

I told you there are several methods available in one of that Kelley's cutting plan method that was the sequential linear programming method we have solved. Now today I will tell you the method of feasible direction that is zoutenijk method, to solve the constraint non-linear programming problem.

(Refer Slide Time: 00:58)

### Zoutendijk's Feasible direction Method

$$\left. \begin{array}{l} s^T \nabla f < 0 \rightarrow \text{descent} \\ s^T \nabla g < 0 \rightarrow \text{feasible} \end{array} \right\} \text{Usable direction}$$

Minimize  $f(x)$   
Subject to  $g(x) \leq 0$   
 $x \geq 0$

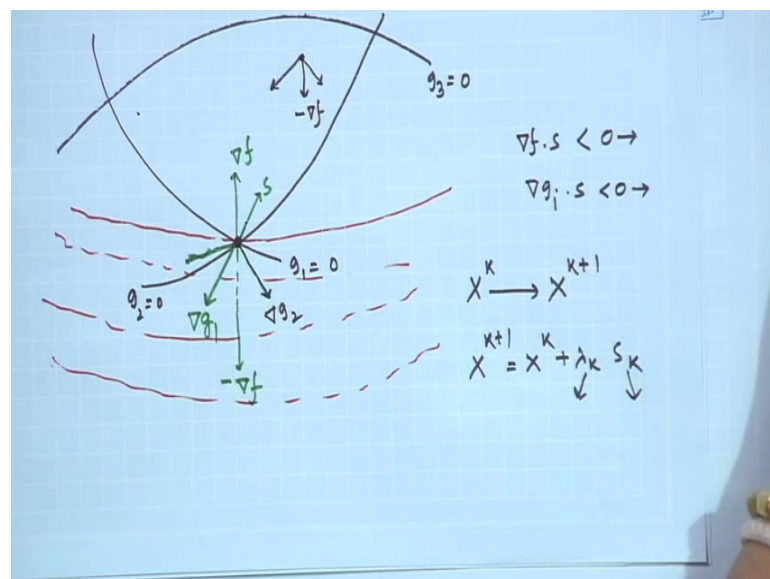

$$x_{K+1} = x_K + \lambda_K S_K$$

Step Length      Direction

Now, let me tell you the basic philosophy of this feasible direction method first.

(Refer Slide Time: 01:15)

Now, if we have constraints like this  $g_1 \leq 0$ ,  $g_2 \leq 0$ ,  $g_3 \leq 0$ . And this is less than equal to that is why this is the feasible space for us, and this is the level curve of the objective function. Then this is the optimal solution this a graph already, we have shown you before. Now at this point you see this direction is the grad of  $g_2$  direction. This let me do the directions with different color, then it will be understandable. And this direction sorry that should be the this must be grad of  $g_1$  that is the normal, if I draw a tangent here at this point this is the

normal to that tangent is the gradient direction at this point of  $g_1$  and at this point if I consider the  $\text{grad } f$  this is the  $\text{grad } f$  direction that is why the opposite this one is the minus  $\text{grad } f$  direction all right.

Now, from here this is a feasible direction from this point, if I move this way is the feasible direction. That is why if I consider this is one of the direction as  $s$ , then we can say that  $s$  is making acute angle with this and  $s$  is making obtuse angle with  $\text{grad } g_1$  or  $g_2$ . That is why you had the relation that  $\text{grad } f \cdot s$  minus  $\text{grad } f$  and you had the relation  $\text{grad } g_i \cdot s$  this is the feasible direction if this is greater than 0 making the acute angle. And for the other thing  $s$  is a feasible direction, if this is less than 0 all right, but on the other way if I tell you in the ascent direction  $\text{grad } f$  is less than 0, but  $\text{grad } f \cdot s$  is less than 0 for the descend direction it is also true.

The Zoutenijk method of feasible direction based on this fact from any point we will find out what is the descent direction for the minimization problem and what is the ascent direction for the maximization problem. As well as we see that what is the feasible direction from this point. This is the this is the direction is happening for the feasible direction. This is the direction for the ascent direction all right. Instead of this point if I consider a point here, what we can see this is the minus  $\text{grad } f$  direction all right. And what about  $\text{grad } g_1$  this is the  $\text{grad } g_1$  direction this is the  $\text{grad } g_2$  direction.

That's why what would be the feasible direction for the for the minimization problem from here, I will move here through these from main any path from this point, I will I have to reach to this point. That is why the method should be such that it should guide me in such a way that if I start my journey from here it should guide me such a way I will end up here all right. If I start from here I should end up here with many with a shortest path I have to come. That is why the Zoutenijk method of feasible direction it has been said that you cross it from a point you cross it to that direction where you are getting, the direction as a feasible as well as decent clear.

From here, if I this is the guess point of my optimal solution. Then you see I cannot move further within the feasible space with this 2 conditions, but if I start from here I can do it if the problem is of maximization type the optimal solution cannot be here. If this is the level curve of the objective function, then optimal solution must be somewhere here. That is why the method should guide me in such a way that if this this point is my

starting point of my journey. For maximization problem I should move through to the through the ascend direction as well as I will go through the feasible direction. That is the basis of the Zoutenijk method of feasible direction.

Now, if we consider a minimization problem of type minimization of  $f(x)$  subject to  $g(x) \leq 0$ , and we can see that descend directions since this is the minimization problem then  $s^T \text{grad } f < 0$ , that is the descent direction and  $s^T \text{grad } g \leq 0$  is the feasible direction refers, direction means what direction means if you remember that I was saying that if I start my journey from  $x_k$  point. Then I will move to the point  $x_{k+1}$  how  $x_{k+1}$  would be  $x_k + \lambda_k s_k$  where  $\lambda_k$  is the step length and  $s_k$  is the direction of the corresponding point.

We can have infinite number of directions, but if we consider a single component of  $n$  dimensional space this direction can be only in the right. Or in the left that way and the Zoutenijk said that if any direction is descent as well as feasible that must be usable direction for the minimization problem. And for the maximization problem if the direction is ascent as well as feasible that is the usable direction that is the term given by Zoutenijk that we will move through the usable direction, we would not said that we will move through the descent direction or ascent direction we will say that we will move through the usable direction.

That's why we will move from  $x_k$  to  $x_{k+1}$  in such way the direction must be usable in nature that is the basic philosophy of Zoutenijk method.

(Refer Slide Time: 08:55)

**Objective:**

1. Iterating proceeds for better minimum through usable direction
2. Remain in feasible space

**Example**

$$\begin{aligned} & \text{Minimize } x_1^2 + x_2^2 \\ & \text{Subject to } x_1 + x_2 \geq 4 \\ & \quad x_1, x_2 \geq 0 \end{aligned}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, this method is a again and iterative process you must be understanding that we will start from a guess point we will move through the next point, we will reach to the next point through the usable direction again we will go to the next point through the usable direction. How long we will do? As long as we can we will remain within the feasible space. Once we fill that we are out of the feasible space we will stop our journey and we will declare that could be the optimal solution that is the beauty of this methodology.

And another thing is that all the points are within the feasible space that is why we will do in such a way that we have to remain on the feasible space. How to define that feasible space? Once we have the constraint set defining feasible space is not a problem for us because we will say that from this point to this point you move you move to such a point where the point must be within the feasible space the point must be in the usable direction. These are 2 things we will mention in the methodology.

That is the beauty of this feasible direction method. And for explaining more about it I am just giving one example what does what does it mean about the decent direction and the that is a feasible direction. This is the problem for us you must be realizing descent direction if corresponds to the objective function and feasible direction refers to the constraint function that is why we will deal both the functions together.

(Refer Slide Time: 10:45)

$$f = x_1^2 + x_2^2 \quad g = -x_1 - x_2 + 4$$

$$\nabla f = (2x_1 \quad 2x_2)^T \quad \nabla g = (-1 \quad -1)^T$$

$$X \equiv (1.45, 2.55)^T \quad S \equiv (s_1 \quad s_2)^T$$

$$\text{descent} \quad s^T \nabla f < 0 \Rightarrow (s_1 \quad s_2) \begin{pmatrix} 2.9 \\ 5.1 \end{pmatrix} < 0$$

$$\Rightarrow 2.9s_1 + 5.1s_2 < 0$$

$$\text{feasible} \quad s^T \nabla g < 0 \Rightarrow (s_1 \quad s_2) \begin{pmatrix} -1 \\ -1 \end{pmatrix} < 0$$

$$\Rightarrow -s_1 - s_2 < 0$$

Find S

$$\text{s.t. } \begin{cases} 2.9s_1 + 5.1s_2 < 0 \\ -s_1 - s_2 < 0 \end{cases} \text{ usable.}$$

Now, we have the function  $f$  as  $x_1$  square plus  $x_2$  square and we will have the function  $g$  that is the constraint function as minus  $x_1$  minus  $x_2$  minus 4 we are making it plus 4. We are making it less than is equal to 0. If we do so, then what is your grad  $f$  grad  $f$  would be  $2 \times 1 \ 2 \times 2$  transpose because that is a column vector. Grad  $g$  would be is equal to minus 1, minus 1 that is again a column vector that is why we are putting it as a transpose.

Let me take one point that is  $x$ , any point within the pace. You check whether this point is within the feasible space or not. If I just add it is it greater than 4 it is coming exactly equal to 4 all right. Let us see which direction is the if I ask you if I start my journey from here which direction will be the descent direction for me because the problem is of minimization time, what you will do? You will find out that you will say  $s$  is a direction  $s$  direction means what you have 2 variables here. Then I will say this direction will have 2 components  $s_1$  and  $s_2$ , again  $s_1$  is related to  $x_1$  and  $s_2$  is relate to  $x_2$  all right.

Then what is the descent direction descent direction would be  $s^T \text{grad } f$  must be less than 0. And what is the feasible direction I showed you with the geometry  $s^T \text{grad } g$  must be less than 0. What we are getting from here that  $s_1 \ s_2$  at this point  $2 \times 1 \ 2 \times 2$  that is why this point is coming 2.9 and this point is coming 5.1 must be less than equal to must be less than 0 no not equal to 0. And this is equal to  $s_1 \ s_2$ , no involvement of  $x_1 \ x_2$  must be less than 0. What we are getting from here we are getting from here, that

descent direction is that direction where (Refer Time: 13:42) point  $9s_1 + 5.1s_2$  must be less than 0 and here the feasible direction is  $-s_1 - s_2 < 0$ .

That's, why if I ask you to find out the usable direction you will say find  $s$  such that  $2.9s_1 + 5.1s_2$  must be less than 0. And must  $-s_1 - s_2$  must be less than 0. That must be the usable direction all right. That is why for any non-linear programming problem if I give you the point, if you know the problem you can find out which would be the usable direction. From that point very nicely clear. If I just draw the graph of it you will get another beauty here,  $x_1^2 + x_2^2 \geq 4$ . That is why if I consider this way this is a 4 0, this is 0 4 and this is a feasible space for us all right.

Now, minimization of  $x_1^2 + x_2^2$ . That is why my objective function is center at 0 a center a circle, it is moving this way, may be here the solution. Here is the solution for you all right for the optimal solution. Where did you see?

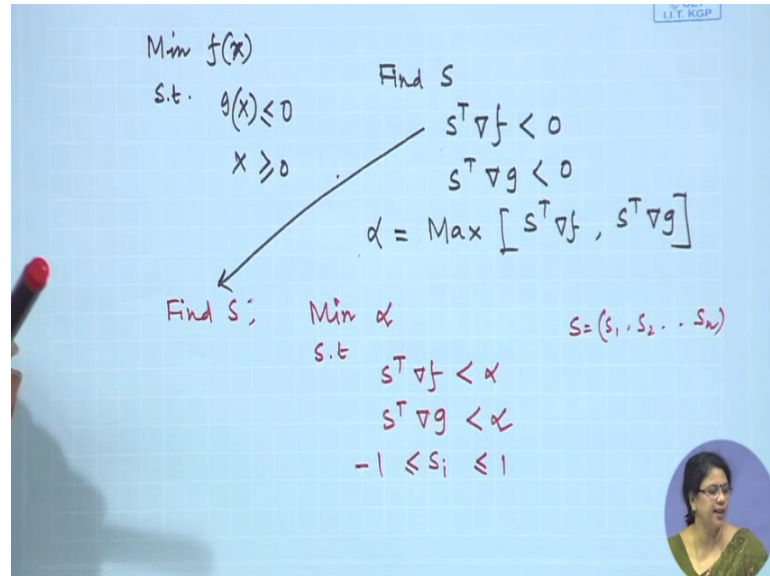

(Refer Slide Time: 14:49)

This direction is the  $\text{grad } f$  direction; these direction is the  $-\text{grad } f$  direction all right. At this point if I consider that this is the tangent at this point then certainly oh sorry if I consider the tangent at this point, this way actually at the optimal solution the I wanted to say that descent feasible cone is empty at the optimal solution. If this is not an optimal solution always we will get a descent feasible cone like this. And this angle will help us a lot in finding it defining the Zoutenijk direction feasible direction method this angle will be named as a theta angle as a push factor our aim is to make theta as 0. So,

that this feasible descent cone will be empty that is the check for optimality. Later on I will show you Zoutenijk method in the next.

(Refer Slide Time: 17:06)

Now, for explaining this thing I am writing the problem once again for you. Minimization of  $f(x)$  subject to  $g(x) \leq 0$  and  $x \geq 0$ . Now our target is to find out the usable direction such that  $s^T \nabla f$  must be less than 0,  $s^T \nabla g$  must be less than 0 all right. Let us introduce one, artificial variable  $\alpha$  such that maximum  $\alpha$  is equal to maximum of  $s^T \nabla f$  and  $s^T \nabla g$ .

Then this problem can be written as this way you see. Find  $s$  minimization of  $\alpha$  in the screen subject to  $s^T \nabla f \leq \alpha$ ,  $s^T \nabla g \leq \alpha$ . From here we can say that find  $s$  such that minimization of  $\alpha$ . Why we are minimizing? Minimizing  $\alpha$ , you see these are all the negative values. We are getting  $\alpha$  as a maximum negative values, but we want to reduce  $\alpha$  still it becomes non positive that is negative that is our target that is why we are reducing  $\alpha$ ; that means, we are finding out minimum of  $\alpha$  subject, to since  $\alpha$  is max of these that then individually this is less than equal to  $\alpha$  this is less than equal to  $\alpha$ . That is why we can write it as  $\nabla f \leq \alpha$ ,  $\nabla g \leq \alpha$ , what did I say I say that  $s$  is a direction  $s$  is a vector, if we have  $n$  dimensional decision when vector then  $s$  will have  $n$  components.

That's why you must be understanding that for individual  $s_i$  where  $s$  would be  $s_1, s_2, \dots, s_n$  in  $n$  dimension individual  $s$ ,  $s_i$  will be in between minus 1 and 1.

(Refer Slide Time: 20:07)

Find  $S$  Minimize  $\alpha$   
 Subject to  $s^T \nabla f \leq \alpha$   
 $s^T \nabla g_j \leq \alpha \quad \forall j$   
 $-1 \leq s_i \leq 1$

Introduce  $\alpha = \text{Max}[s^T \nabla f, s^T \nabla g_j]$

Minimize  $-\beta$   
 Subject to  $s^T \nabla f + \beta \leq 0$   
 $s^T \nabla g_j + \theta_j \beta \leq 0 \quad \forall j$   
 $-1 \leq s_i \leq 1$   
 $\beta > 0$

$\theta_j \rightarrow$  Path factor

$t_i = s_i - 1, \quad i.e. 0 \leq t_i \leq 2$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

That is the given condition for us that is why we can say that that's why we can redefine the problem as this way. Minimize alpha subject to  $s_i$  in between minus 1 and 1. One thing you see  $\text{grad } f$  is a  $\text{grad } f$  we will get from here a linear function that I just wanted to say. This is a linear function, this is a linear function, this is a linear function. That is why if we want to have the linear programming problem we have a constraint that if I want to apply the simplex algorithm basic constraint in simplex algorithm is that all the decision variables must be nonnegative.

That's why we cannot have any decision variable as negative value. We have considered as alpha as max of  $s^T \text{grad } f$   $s^T \text{grad } g$ . That is why alpha is negative if I keep as a minimization of minus alpha within the problem it minimization of alpha within the problem itself then I have to declare alpha as non positive, but simplex will not accept it simple algorithm. As I said the constraints are becoming the linear constraints. That is why it cannot be to make it positive I am considering another variable beta, considering beta is equal to minus alpha then beta must be positive. If alpha is negative beta is positive that is why minimization of alpha will become minimization of minus alpha. And alpha if I replace alpha with beta it will become  $s^T \text{del } f$  plus beta less than is equal

to 0,  $s^T \Delta g_j \geq 0$  because there are  $j$  number of constraints  $j$  can be from 1 to  $m$  number of constraints plus  $\beta$  less than is equal to 0.

Now, here in Zoutenijk method feasible direction method. Here we can consider a factor that is the factor is factor  $\theta$ . You see  $\alpha$  is the variable that is the constant value,  $s$  is a vector  $\Delta f$  is a vector  $\Delta g$  is a vector, but  $s$  is a vector  $s$  vector is what that is the usable direction. We are not really interested for the magnitude of that vector we are interested about the direction of  $s$ . That is why we kept direction from minus 1 to 1, we have taken the normalized value of  $s$ , but we are more concerned about the magnitude of  $\Delta f$  magnitude of  $\Delta g$ . All right  $\beta$  is something relates to the magnitude of  $\alpha$ , but you see  $\theta_j$  is an angle which angle refers to the angle of descent feasible cone that is the usable cone. What is our target our target is to push  $\theta$ ? If  $\theta$  is equal to 0 means what the constraint is tangent, that is why in other cases always  $\theta_j$  will be greater than 0 it cannot be less than 0, less than 0  $\theta_j$  impossible.

That's why this push factor we have considered with  $\beta$  only, by taking  $\theta_j$  as greater than 0. That is why the original problem we had original problem minimization of  $f(x)$  subject to  $g_j(x) \leq 0$ . Now it is becoming a problem of this kind minimization of  $-\beta s^T \Delta f + \beta$  less than is equal to 0,  $s^T \Delta g_j + \theta_j \beta$  less than is equal to 0.  $\theta_j$   $\theta$  is again it is having different components for one constraint for the  $j$ th constraint the component is  $\theta_j$  for  $\theta$  all right.

Now, for that is why individual  $\theta_j$  must be greater than equal to 0. In at the optimal stage for one constraint  $\theta_j$  is equal to 0, for other constraints it may not be in that way this is the push factor we are considering, but again you say this is if we consider as a linear programming problem. The problem is again here is that we cannot take  $s$  as a negative value. Though we have consider  $s$  as a magnitude of the vector for the usable direction, and that is why we took the normalized value from minus 1 to 1, but once it is coming as a linear programming problem all the decision variables must be positive.

Then let us have certain mechanisms. So, that this negative variable will be converted to positive variable, that is why we will consider that one factor  $t_i$  that is equal to  $s_i - 1$ .

(Refer Slide Time: 25:44)

Find  $(t_1, t_2, \dots, t_n)$  which

Minimize  $-\beta$

Subject to  $t_1 \frac{\partial g_j}{\partial x_1} + t_2 \frac{\partial g_j}{\partial x_2} + \dots + t_n \frac{\partial g_j}{\partial x_n} + \theta_j \beta \leq \sum_{i=1}^n \frac{\partial g_1}{\partial x_i}$

$$t_1 \frac{\partial f}{\partial x_1} + t_2 \frac{\partial f}{\partial x_2} + \dots + t_n \frac{\partial f}{\partial x_n} \leq \sum_{i=1}^n \frac{\partial f}{\partial x_i}$$
$$0 \leq t_i \leq 2$$
$$\beta > 0$$

IIT KHARAGPUR

NPTEL ONLINE  
CERTIFICATION COURSES

So, that  $s_i$  is becoming from minus 1 to one then  $t_i$  will be from 0 to 2. That is the beauty of this method. Once we can have it then the whole problem can be rewritten as this one, that find out the direction this is the component of  $s$  such that  $s^T \Delta g + \theta_j \beta$  that is the push factor into  $\beta$  less than is equal to 0. And this is less than is equal to 0 and  $t_i$  in between 0 to 2 and  $\beta$  greater than 0.

What how it is being expanded that you will get it if you just take the first order derivative of the constraint with respect to decision variable, because we have that factor with us.

(Refer Slide Time: 26:38)

**Algorithm**

Step 1: Start with initial feasible point  $x_1$ .  
Evaluate  $f(x_1)$  and  $g_j(x_1) \forall j$ . Set  $i = 1$

Step 2: If  $g_j(x_i) < 0$  (i.e. interior point)  
feasible direction  $s_i = -\nabla f(x_i)$   
Normalise  $s_i$  and go to step 5  
if at least one  $g_j(x_i) = 0$  go to step 3.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

And if I just tell you I will tell you more about the zoutenijk feasible direction method, with example I show how it is being expanded in this manner in the next class, but before to that I will tell you the algorithm once.

Take the initial feasible point  $x_1$  that is of your own choice. If your choice is good enough then your number of iterations will be less. Now find out  $f$  and  $g$  at that point then if  $g_j$  is less than 0 then must be in the interior point. Now find out the feasible direction as  $-\nabla f(x_1)$  at that point that is the feasible direction.

(Refer Slide Time: 27:35)

**Algorithm**

Step 3: Find usable direction  $s$  by

$$\begin{aligned} & \text{Minimize } -\beta \\ & \text{Subject to } s^T \nabla f + \beta \leq 0 \\ & \quad s^T \nabla g_j + \theta_j \beta \leq 0 \quad \forall j \\ & \quad -1 \leq s_i \leq 1 \\ & \quad \beta > 0 \end{aligned}$$

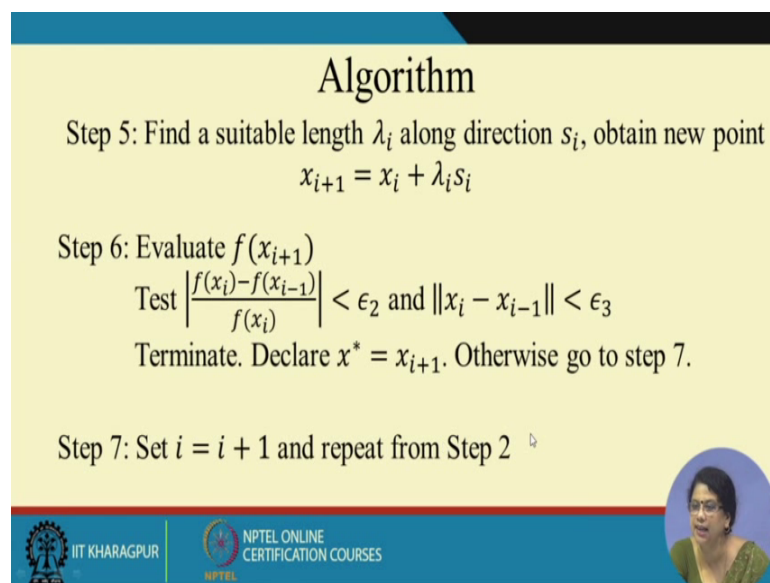

Step 4: If  $\beta^* \cong 0$  i.e.  $\beta^* < \epsilon_1$ . Stop iteration  
Conclude  $x_i$  as  $x^*$  (Optimal solution)  
If  $\beta^* > \epsilon_1$  go to step 5

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, that  $s^T \text{grad } g$  must be less than 0 that is why that is a direction feasible direction and  $g_j$  you have to consider, then you construct this problem considered  $t_i$  in such a way that it will become from 0 to 2. Take  $\beta$  corresponds to minus  $\alpha$  we want to reduce  $\alpha$  that is why our target to make  $\alpha$  as 0 that is why in other hand we are making  $\beta$  as 0.

That is why our stopping criteria would be if the  $\beta$  value is very small, we can conclude that the optimal solution is that one that is the thing for you.

(Refer Slide Time: 28:12)

The slide is titled "Algorithm" and contains the following steps:

Step 5: Find a suitable length  $\lambda_i$  along direction  $s_i$ , obtain new point  
$$x_{i+1} = x_i + \lambda_i s_i$$

Step 6: Evaluate  $f(x_{i+1})$   
Test  $\left| \frac{f(x_i) - f(x_{i-1})}{f(x_i)} \right| < \epsilon_2$  and  $\|x_i - x_{i-1}\| < \epsilon_3$   
Terminate. Declare  $x^* = x_{i+1}$ . Otherwise go to step 7.

Step 7: Set  $i = i + 1$  and repeat from Step 2

The slide footer includes the IIT Kharagpur logo, the NPTEL Online Certification Courses logo, and a small circular portrait of a woman in the bottom right corner.

Now, this is a step 5 once we get  $s$ , I will get the lengths suitable length we will find out. And this is the check for optimality, and we will do the solution for this. We will repeat again and again, now I will explain more about this algorithm the calculation part of the feasible direction method along with the example in the next class.

Thank you very much for today.
