Lecture – 56
Penalty and barrier method

Today, I will talk on interior penalty function method or web area method. This is another technique indirect method for solving non-linear programming, constraint programming problem.

(Refer Slide Time: 00:44)

Let us consider a general NLP problem

$$\text{Find } X = (x_1, x_2, \dots, x_n)^T \in R^n \text{ which}$$
$$\text{Minimize } f(X)$$
$$\text{Subject to } g_j(x) \leq 0 \quad j = 1, 2, \dots, m$$

Above NLP may be rewritten as an unconstrained problem as follows:

$$\underbrace{\text{Minimize}}_{X \in R^n} f(X) + \sum_{j=1}^m C_j B_j(X)$$

The slide also features the IIT Kharagpur and NPTEL logos at the bottom left and a small video inset of the professor at the bottom right.

Now let us consider again the non-linear program; that is minimization of $f(X)$ subject to $g_j(X) \leq 0$ is a set of non-linear constraints are there. Now this barrier method or the interior penalty function method. Here we are considering again the penalty, penalty of not getting the optimal solution. We have to bear it and we will try to minimize the penalty function. Now in, that is why this kind of methodology, we are just converting the constrained non-linear programming problem into unconstrained non-linear programming problem.

Now, for minimization type of problem we are considering the penalty function as positive penalty function, because we are trying to minimize the objective function as well as we are trying to minimize the penalty function. Now in the penalty term, there are 2 components; one is the penalty parameter and another one is the penalty function.

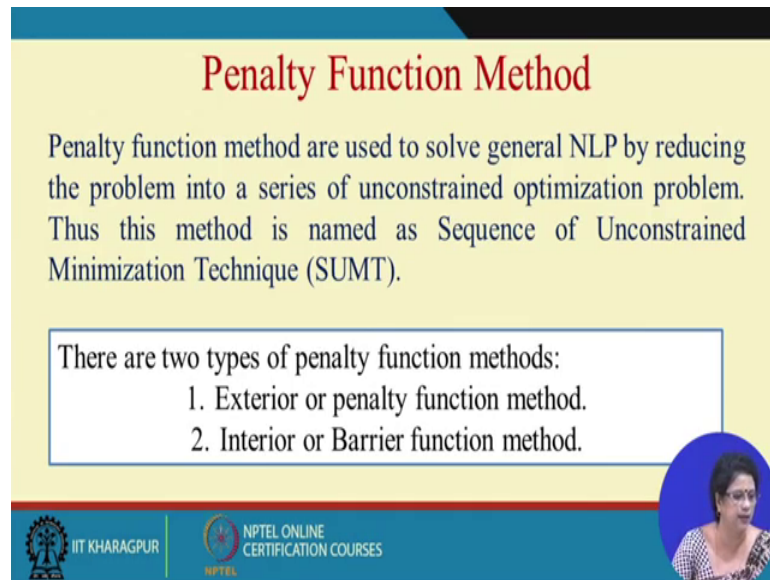

Now, we are concerned about the penalty term, in minimization problem, we are minimizing the penalty term and for the maximization problem negative of the penalty function, we have to maximize, because penalty maximization of a objective function does not mean that maximization of the penalty function, as well penalty is something that is not desirable. We are incurring penalty, because the corresponding point rather the corresponding. See corresponding location of mine of my algorithm; that is not optimal, that is either within the feasible region for the interior penalty function, and for exterior penalty function. This point will be outside the feasible region, that is why we can just convert this constraint minimization problem as unconstrained minimization problem, as minimization of a objective function summation $C_j + B_j$, where B_j is the penalty function.

In interior method we call it as a barrier function. Why we are calling it as a barrier function. I will just discuss later on, but this is a penalty function. If the point is not in the optimal or rather the boundary of the feasible region, this barrier functional value will be positive. Now, C_j will be the corresponding penalty parameter, as a whole we are having a summation of all penalty terms. Now as many number of constraints we are having that many number of penalty terms, we will have, that is why we will have this is a unconstrained problems, and this can be solved either through the differential calculus approach by considering the first order necessary condition, second order optimality condition, or we can choose any region elimination technique as well, for solving this kind of problem, but using the region elimination technique, you know there are certain restrictions to it, because in the region elimination technique the function must be unimodal, then only, but this in this case.

Once we are having $f(X)$ as a non-linear function, that non-linear function can have different modes, different peak points, minimum peak or maximum peak. We are trying to find out the global minimum or global maximum for the corresponding problem. Similarly for the function $g(X)$, that is also non-linear, when we are adding these 2 terms, we are not sure, we cannot expect even always the function will have unimodal within a range of definition, that is why region elimination technique. If you want to apply, then we have to break the intervals in to different parts, and in different parts we need to check the unimodality of the function, then only we can use the region elimination technique. But in general this kind of non-linear programming problems, the objective

function as well as the constraint, these are all continuous in nature; that is why, but it uses the simple technique, we know that is the differential calculus approach that is the classical optimization techniques we can adopt it.

(Refer Slide Time: 05:42)

Penalty Function Method

Penalty function method are used to solve general NLP by reducing the problem into a series of unconstrained optimization problem. Thus this method is named as Sequence of Unconstrained Minimization Technique (SUMT).

There are two types of penalty function methods:

1. Exterior or penalty function method.
2. Interior or Barrier function method.

The slide features a yellow background with a blue header and footer. The title 'Penalty Function Method' is in red. The main text is in black. A white box with a blue border contains the list of two types of methods. The footer includes the IIT Kharagpur logo, the NPTEL logo, and the text 'NPTEL ONLINE CERTIFICATION COURSES'. A small circular inset image of a woman is visible in the bottom right corner of the slide.

Now, this we know that for the exterior penalty function method, there is a penalty term and we are naming it as a penalty function, but for interior penalty function method, this is the barrier, but we are having a sequence of unconstrained optimization problem, that is why this kind of penalty methodologies is being termed as SUMT, that is a sequence of unconstrained minimization technique and this is for the minimization problem. If we have the maximization problem, then we will have the sequence of unconstrained maximization technique. This methodology is being named as termed as.

(Refer Slide Time: 06:28)

Barrier or Interior penalty function methods

Introduces penalty if there is violation of constraints, as follows

$$\text{Minimize } f(X) + CB(X), \quad X \in S \cup \mathbb{R}^n$$

Where, $S = \{g_j(x) \leq 0 \quad j = 1, 2, \dots, m\}$

What is C and $B(X)$????

The slide features a blue header and footer. The footer contains the IIT KHARAGPUR logo on the left and the NPTEL ONLINE CERTIFICATION COURSES logo on the right. A circular video inset in the bottom right corner shows a woman with glasses speaking.

Now, there are different penalty function you must have realized in exterior penalty function method. Similarly here also we are having different kind of barrier function, but the barrier function should have certain property, if you say that we are right, if we just make the unconstrained object objective function as $f(X) + CB(X)$, then we need to know what is a property of $B(X)$, what is the property of C , how C and $B(X)$ are behaving. 1 thing is clear that it is, the process is moving we are having a sequence of unconstrained optimization problem, but all the problems are being defined within the feasible region, that is why the behavior of C and B must be examined. For this case, because the behavior will not be same as exterior method.

(Refer Slide Time: 07:26)

Barrier function methods

Introduces penalty if there is violation of constraints, as follows

$$\text{Minimize } f(X) + CB(X), \quad X \in \mathbb{R}^n$$

1. $B(X)$ is continuous
2. $B(X) \geq 0$
3. $B(X) \rightarrow \infty, X$ approaches to boundary of S

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, if I want to get the property, if you ask me what is a property of $B(X)$, then again I should mention the same just like your n exterior penalty function method that you are barrier function must be positive throughout and barrier function is continuous. Since $g(X)$ is continuous bear $B(X)$ is the function of $g(X)$ that is why $B(X)$ is continuous $B(X)$ is positive and $B(X)$ is tending to infinity as X approaches to the boundary of S S is the feasible region of the. Now, you see whenever we are writing minimization of $f(X)$ plus $C B(X)$. Here we are not considering X within the feasible space, you must have been, must have seen that we are considering X is in \mathbb{R}^n , \mathbb{R}^n , we are considering, because for the ponds where the ponds are outside the feasible space in that case, $B(X)$ will be 0, but once it is within the feasible space then $B(X)$ is positive all right, but there is a trained of $B(X)$ as well just like your $P(X)$ as you have seen.

(Refer Slide Time: 08:45)

The slide is titled "Barrier function methods" in red text. Below the title, it says "Introduces penalty if there is violation of constraints, as follows". There are two boxed equations: a blue box containing "Minimize $f(X) + CB(X)$, $X \in \mathbb{R}^n$ " and a green box containing two formulas: $B(X) = -\sum_{j=1}^m \frac{1}{g_j(X)}$ (Inverse Barrier function) and $B(X) = -\log \sum_{j=1}^m (-g_j(X))$ (Log Barrier function). The slide footer includes the IIT Kharagpur logo, the NPTEL Online Certification Courses logo, and a small video inset of a woman speaking.

Now, $B(X)$ is being measured as a violation penalty, because of violation of constraint. Now, one barrier function can be considered as 1 by constraint function, if we are having 1, can 1 constraint functions $g(X)$, then barrier function can be considered as minus 1 by $g(X)$. You see $g(X)$ is always less than or equal to 0 in general model, we are considering our model is minimization of $f(X)$ subject to $g(X) \leq 0$; that is why within feasible space $g(X)$ is always less than or equal to 0. But outside the feasible space $g(X)$ is greater than or equal to 0, but if we consider within the, we are within the feasible space, we are starting our sequence from the feasible region only, that is why $1/g(X)$ will be always negative, and if we consider minus $1/g(X)$, then it will be positive all right. This is one of the barrier function, this barrier function is being named as the inverse barrier functions.

There is another kind of barrier function that is the logarithm barrier function, there we are considering the barrier function as minus log minus $g(X)$; that is also gives you $B(X)$ as positive, because $g(X)$ is negative that is why. Now this summation is being considered, because this summation gives you the value for all constraints together, we are considering all $1/g_j(X)$ for all $g_j(X)$ that is why this way we will consider the barrier function.

Now, if you remember I was talking, I was just explaining one problem that minimization of $f(X)$ $X \geq 5$. Now once we were considering $f(X)$ equal to X

as objective function X greater than equal to 5 as a constraint, then if I just make it in the form of, in the form of $g(X) \leq 0$, then I will write down it as $5 - X \leq 0$. Now you are object, your feasible region is $X \geq 5$. Now for $X = 6$, now value will be negative ultimate 1 by $g(X)$; that is why $5 - 6$ that would be negative that will be -1 and another minus is there with $B(X)$; that is why it will be the penalty, you need to incur, that is 1 for $X = 7$ penalty, you need to incur as 1 by 2 in this way.

But you see if we considered, if we are just reaching to the boundary of the feasibility region by considering $X = 5$ though $X = 5$ as the optimal solution of the problem; that is a, advantage of this methodology is that we will get the unbounded solution, because 1 by $X - 5$ and $X = 5$ it will give you infinity. That is why this barrier function has the disadvantage that always it makes a barrier within the feasible space by constructing the unconstraint function that is why this method is being named as the barrier function method that is the barrier we are considering within the space.

Now, let us consider this 2 barrier functions in a interior penalty function method.

(Refer Slide Time: 12:39)

Barrier or Interior penalty method

Let $\{C_k\}$ be a nonnegative, monotonically increasing sequence.

Define $r(C_k, X) = f(X) + C_k B(X)$

Assume that the problem $\text{Min } r(C_k, X)$ has solution X_k for each k

- As C_k **decreases** it generates a sequence of minimum which all lie in the feasible region
- $C_k \rightarrow 0$ and $P(X) \rightarrow \infty$ as X approaches to optimal solution

 IIT KHARAGPUR |
  NPTEL ONLINE CERTIFICATION COURSES

Now, if we again consider the, there is a sequence of C . Now we got the impression what should be the, what should be the case, what should be the property of $P(X)$, that is the barrier function, but we do not know what is the property of C . How C behaves within

the feasible space, if I want to move towards the feasible space, not exactly the boundary of the feasible space, at least towards the feasible space. Then whether C value will increase or decrease, as we have seen for the interior penalty function method, the value of C is always, if we just increase it, then we will reach to the boundary of the feasible region, but in this case, they will see if we just reach, if we just decrease the value of C we will reach to the boundary of the feasible region. We will have a field with certain examples, but for different C we will get a sequence of unconstrained optimization problems, that is why if we consider k as the index of iteration starting from k equal to 1, then C_1 will be considered such a way that we will be within the feasible space ok.

Now, C_2 will be considered C_2 must be lesser than C_1 , then only we can move towards the feasible boundary of the feasible region, that is why in this method instead of increasing C , we have to decrease C , but there is another convention, you will see in the literature that in the barrier function method, people are not considering the constant term, that is the parameter barrier parameters C_k as C_k . They consider 1 by c_k that convention is there, why it is. So, because to make c_k as similar as the exterior penalty function method as we are saying, that we are trying to decrease C_k , if I make c_k as 1 by c_k , then we can say that we are increasing 1 by c_k that is why that convention is there.

Otherwise if C_k tending to 0 , we will see the barrier function will tend to infinity, because if $g(x)$ is equal to $5 - x$ less than is equal to 0 , then 1 by $g(x)$ is equal 1 by $g(x)$ at x equal to 5 is infinity; that is why this barrier function that is a $P(x)$ its not $P(x)$, that is $B(x)$, that $B(x)$ will go to infinity if x approaches to the optimal solution, that is the understanding; that is why for this case if I want to solve the non-linear optimization problem, then we have to select k C in such a way that we will remain in the feasible space all right. And this selection is not really so easy why, because this selection is the C value is very high, then in that case we will be far from the feasible space, what should be the optimal value for C , what is the suitable value for C , that is also a question, because we are assuming certain C value, these are all the disadvantage. There are different methodologies available for non-linear constraint programming problem, that because of this drawbacks all right.

(Refer Slide Time: 16:20)

Barrier or Interior penalty method

Let $\{C_k\}$ be a nonnegative, monotonically increasing sequence.

Define $r(C_k, X) = f(X) + C_k B(X)$

Assume that the problem $\text{Min } r(C_k, X)$ has solution X_k for each k

- $C_k \rightarrow 0$ and $P(X) \rightarrow \infty$ as X approaches to optimal solution
- If the constraint is satisfied critically, then the solution is not obtained

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, let us just try to solve the problem, and it has been written if the constraint is satisfied critically, then the solution is not obtained, the solutes the problem will be unbounded, objective function will be unbounded; that is the.

(Refer Slide Time: 16:42)

Example

1. Minimize $(1 - x)$ Subject to $x \leq 1$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, let us consider one problem minimization of $1 - x$ is subject to $x \leq 1$. Let us consider it if this, then let me make the unconstrained, problem as $C_k x = 1 - x - C_k$, and let me x use the logarithm barrier function,

then $\ln(1-x)$ will be $1-x$; that means, it is $1-x$ all right, by using the logarithm barrier function.

(Refer Slide Time: 16:58)

$$\text{Min } r(c_k, x) = (1-x) - c_k \ln(1-x)$$

$$f(x) + c_k B(x) \quad B(x) = -\ln(1-x) \quad 0 < x < 1$$

FONC $\nabla r = 0$

$$-1 + \frac{c_k}{1-x} = 0 \Rightarrow \frac{x-1+c_k}{1-x} = 0$$

$$\Rightarrow x = 1 - c_k$$

$c_1 = .99995$	$x^* = .00005$	$c_k \rightarrow 0$ $x^* \rightarrow 1$
$c_2 = .1$	$x^* = .9$	
$c_3 = .01$	$x^* = .99$	
$c_4 = .001$	$x^* = .999$	
$c_5 = .0001$	$x^* = .9999$	
$c_6 = .00001$	$x^* = .99999$	

Now, we have to minimize this objective function where this is the function $f(x)$ plus C_k barrier function, where barrier function is equal to minus $\ln(1-x)$, where $0 < x < 1$ clear.

Now if I want to minimize let us consider the first order necessary condition, then gradient of r must be equal to 0. Now there is only 1 variable here, that is why we can see that this is equal to $-1 + \frac{c_k}{1-x}$, and because of $1-x$ this is plus this is equal to 0 all right, this is the first order condition if I just take x then $1-x + c_k = 0$. From here we are getting $x = 1 - c_k$ clear, that is why let me consider first c_k is equal to 1, let consider c_1 is equal to sum value point very high value you will start, 0.995.

Then what will be corresponding optimal solution for this x term must be $1 - c_k$, that is why the x^* value will be 0.0005. Now I have to increase c_1 , I have to decrease c_1 , that is why let me consider c_2 as 0.1, then corresponding x^* would be is equal to 0.9 all right, if I consider c_3 is equal to 0.01, then x^* would be is equal to 0.99. c_4 is equal to 0.001 x^* would be is equal to 0.999. Similarly c_5 , what you see the pattern it is approaching to 1 c_6 .

We can go further what we see that if C_k is tending to 0, X^* is approaching to 1, that is why we can say X^* is equal to 1 could be the optimal solution for this problem, this way we can solve this problem.

(Refer Slide Time: 20:25)

Algorithm

Step 1: Start with an initial feasible point x_1 ,
 Such that $g_j(x_1) < 0, \forall j$. For some $C_j^1 > 0, \forall j$ formulate the unconstrained problem and find minimum x_2 using x_1 as given optimal. Set $k = 1$.

Step 2: Choosing $C_j^{k+1} < C_j^k (\forall j)$ (Where, $C_j^{k+1} = bC_j^k, b < 1$). Solve above unconstrained problem using x_{k+1} as guess optimal using any unconstrained optimization method.
 Set $k = k + 1$.
 Repeat the process so that a strictly monotonic decreasing sequence $\{u^k\}$ is obtained.

Now, if I say what is the algorithm for solving this exterior penalty function method, sorry interior penalty function method. First of all we have to select a value for C_1 for k is equal to 1 the consideration of C_1 depends on the feasible point that is why we will consider a feasible point within the space. Now let us start the initial feasible point at X_1 such that $g_j(X_1) < 0$.

Now, in this case as it was for exterior penalty function method that we have to consider 1 point which is outside the feasible space, how we checked it. We checked it, we were considering point which was, if there are 3 constraints we were checking at least 1 of the constraint should not be satisfied with that point, but in the interior penalty function method we need to consider that all constraint must be satisfied, then only this is the feasible point, that is why X_1 must be feasible point for all j . Now once we are getting $C_1 > 0$ formulate the unconstrained problem find the minimum, and check for optimality, check for optimality. The only thing we cannot do, because unless we just process it now, because we are more interested to get the sequence of unconstrained problem.

And we will say that you see we are converging a C_k tending to 0, we are converging that sequence the limit point of the sequence is this one. Now that is why we are

considering another C; that is lesser than the previous C, then again we are just doing the process, and we are getting the solution this way let me consider another problem.

(Refer Slide Time: 22:24)

Example
 Minimize $f(X) = x_1 - 2x_2$
 subject to, $1 + x_1 - x_2^2 \geq 0$
 $x_2 \geq 0$

For this $X_1 - 2X_2$ subject to $1 + X_1 - X_2^2 \geq 0$ if this is the problem for us then we can say that, $R_C k X$ must be is equal to $X_1 - 2X_2$ minus; if I considered $g X g X$ will be $X_2^2 - X_1 - 1$ less than is equal to 0.

(Refer Slide Time: 22:43)

© CEY
I.I.T. KGP

$$r(c_k, x) = x_1 - 2x_2 - c_k \frac{1}{x_2^2 - x_1 - 1} \quad x_2^2 - x_1 - 1 \leq 0$$

• $\nabla r = 0$

$$r(c_k, x) = f(x) - c_k \sum \frac{1}{g_j(x)}$$

$$\nabla r = \nabla f(x) + c_k \sum \frac{1}{(g_j(x))^2} \nabla g_j(x)$$

$$c_k \sum_{j=1}^m \frac{1}{(g_j(x))^2} \rightarrow \lambda^* \quad \text{as } x \rightarrow x^*$$

$\lambda^* < \infty$

Now, this problem we have already solved, with a interior penalty function method exterior penalty function method, and I am just considering this as $C \sqrt{x_1^2 + x_2^2 - 1}$, and you solve this problem with exterior penalty function method by considering δr is equal to 0, find out the value for x_1 and x_2 in terms of C then you take C tending to 0, and find out the value of it.

In this process one thing I just I would like to say that you see we are considering $r = C \sqrt{x_1^2 + x_2^2 - 1}$ is equal to $f(x) - c \sqrt{\sum_{j=1}^m g_j(x)}$, and what is the $\text{grad } r$, $\text{grad } r$ is equal to $\text{grad } f(x) + c \sum_{j=1}^m \frac{1}{g_j(x)} \text{grad } g_j(x)$. Now you see look at this term you recall the Kuhn Tucker conditions. What was one of the condition in the Kuhn-Tucker condition for inequality constraints that was the $\text{grad } f(x) + \text{Lagrange multiplier grad of } g_j(x)$. Here also we can say that $c \sum_{j=1}^m \frac{1}{g_j(x)}$ is equal to 1 to $m-1$ by $g_j(x)$ whole square tending to λ^* ; that is the Lagrange that is the KKT multiplier as x tending to optimal point all right. Now what are the other thing is we can say that λ^* is equal to 0 for active constraint, and λ^* not is equal to 0 for inactive constraint here. Also we can say when this λ^* is finite value then we can say that.

We are getting that corresponding λ^* corresponding g_j would be the this is finite active constraint all right, this is one consideration. Now let me take one another example for solving with the interior penalty function method.

(Refer Slide Time: 26:25)

$$\text{Min } x_1^2 + x_2^2 \quad \text{Subject to, } 1 - x_1 - x_2 \leq 0$$

$$r = x_1^2 + x_2^2 - C \ln(x_1 + x_2 - 1)$$

$$\nabla r = \begin{pmatrix} 2x_1 - \frac{C}{x_1 + x_2 - 1} \\ 2x_2 - \frac{C}{x_1 + x_2 - 1} \end{pmatrix} = 0 \Rightarrow x_1^* = x_2^* = \frac{2 \pm 2\sqrt{1+4C}}{8}$$

$$\frac{2 - 2\sqrt{1+4C}}{8} \notin \text{Feasible space}$$

$$\frac{2 + 2\sqrt{1+4C}}{8} \in \text{Feasible space}$$

C	x_1	x_2	r	λ
1.9				
1.8				
1.7				
⋮				

$$C \rightarrow 0 \quad x_1 \rightarrow \frac{1}{2} \quad x_2 \rightarrow \frac{1}{2} \quad \left(\frac{1}{2}, \frac{1}{2}\right) \text{ is the optimal sol.}$$

Minimization of $X_1^2 + X_2^2$ subject to $1 - X_1 - X_2 \leq 0$ consider the barrier function r is equal to $X_1^2 + X_2^2 - C \ln(1 - X_1 - X_2)$, that is why it will be $X_1 + X_2 - 1$ all right.

Consider the grad of r grad of r would be is equal to $2X_1$, if I just differentiate with respect to X_1 , this is $2X_1 - C/(1 - X_1 - X_2)$, and if I just partially differentiate with respect to X_2 , this is equal to $-C/(1 - X_1 - X_2)$, this must be is equal to 0. And this gives you the at the optimal stage X_1^* must be is equal to X_2^* , because if we just equate equal to 0, this is less than is equal to 0 this 2 terms from there, we can say that X_1^* is equal to X_2^* not only that, we can say that this is equal to $2 \pm \sqrt{1 + 4C} / 8$ plus minus, because we will get the condition, like this. If we just substitute X_1 is equal to X_2 here, then we will get this equation with of degree 2 from there, we will get 2 roots of the equation.

Now, one point that is if we just substitute the values here, we will see that $2 - \sqrt{1 + 4C} / 8$ is not within the feasible space, that is why only the point we have, that is in the feasible space $2 + \sqrt{1 + 4C} / 8$, this is in the feasible space. Now, one thing you can do by changing the value or see you will get sequence of sequence of optimal solutions, because we know X_1^* is equal to X_2^* star we can have for different values of C starting from say 0.9 0.8 0.7 X_1 we can have X_2 we can have functional value the r we can have, we can have the functional value as well we can have a table like this, we will get. By substituting the value of C 0.9 we will get $1 + 4 \times 0.9$ root of that 2 into this etcetera, then that would be the value for X_1 same is the value for X_2 , we can complete this table, this is one way of getting, and we will see that where X_1 X_2 values are converging in the corresponding r value will converge or f will converge that would be the solution other way, what we can do, we can take C tending to 0.

If C tending to 0 what we see that X_1 value will tend to $2 + 2 / 8$; that means, half X_2 value is tending to half, that is why we can declare half is the optimal solution same thing, you will get through this table as well what I suggest you just check it, and for the previous problem also just do the same exercise for that problem also.

Thank you for today.
