Lecture – 52
Conjugate Gradient Squared and Biconjugate Gradient Stabilized

Welcome. We are discussing about Biconjugate Gradient Method and we are trying to demonstrate the developments over Biconjugate Gradient Method, where the number of computational steps in terms of matrix vector multiplication could be reduced. And also looking into the possibilities of reducing the matrix eliminating the matrix transpose and vector multiplication step.

So, on developing that method in a on a step towards that we discussed that the residual and the auxiliary vector in both the Krylov subspace of A as well as Krylov subspace of A transpose can be expressed as 2 different polynomial functional of A and A transpose. The functional phi is defined for just you have been did it in the last class as the polynomial functional phi is for residual and polynomial function pi is defined for the auxiliary factor..

And we are trying to develop transpose V is variant of Biconjugate Gradient Method..

(Refer Slide Time: 01:26)

Transpose Free Variants of BCG

Using polynomial expressions, parameters α_j can be written as:

$$\alpha_j = \frac{(r_j, r_j^*)}{(Ap_j, p_j^*)} = \frac{(\phi_j(A)r_0, \phi_j(A^T)r_0^*)}{(A\pi_j(A)r_0, \pi_j(A^T)r_0^*)} = \frac{(\phi_j^2(A)r_0, r_0^*)}{(A\pi_j^2(A)r_0, r_0^*)}$$

Similarly, β_j can be found as

$$\beta_j = \frac{(r_{j+1}, r_{j+1}^*)}{(r_j, r_j^*)} = \frac{(\phi_{j+1}^2(A)r_0, r_0^*)}{(\phi_j^2(A)r_0, r_0^*)}$$

So, now the parameter α is written as $\alpha = \frac{r^T r}{r^T A p}$ and we write try to write all the polynomial functional instead in cases of r and p $\phi_j A r_0$ which is polynomial form of r and $\phi_j A^T r_0$.

Similarly $A A^T p$ is $\phi_j A r_0$ and $p^T A^T r_0$ is $\phi_j A^T r_0$. Now r_0 is a vector which is multiplied with the polynomial function. This is this will be supposed to be a suppose it be a polynomial of a matrix. So, when we do this product, we get ϕ_j . So, this vector will come out and this is this is the dot product which is between these 2 vectors.

So, this will be $\phi_j A r_0^T r_0$ and we will get $A \phi_j$ a similarly $r_0^T r_0$. So, we in order to find out α instead of doing A^T etcetera, if we can evaluate the matrix the polynomials we have to find out the polynomial product of ϕ_j square A and $A \phi_j$ square A also you need to get $r_0^T r_0$ and multiply it with that. Similarly in the other parameter β can be found as $r_j^T r_j$ star r_j star plus 1 divided by $r_j^T r_j$ star which is similarly if we replace the values of r_j plus 1 r_j etcetera we will get ϕ_j plus 1 square $A r_0$ ϕ_j square $A r_0$.

Now, the issue is that that are we actually reducing our steps, if we assume some polynomial form of the residue and the auxiliary vector. If we try to look it as apparently as it is coming that we are not reducing the steps because doing this, finding this polynomial and doing the square of this polynomial will be itself very cumbersome step. So, what will try to do is to develop a recursive relation here.

So, that we really do not have to do the all the calculations at you every step doing square finding doing lot of operations on a matrix rather we can use some simple recursive relation and trying this out. And now we will look into few variant sub that of this method few of the transpose p variants of the method.

First is the conjugate gradients square method, where r_0 the residue norm r will be assumed to of A to behave in a certain polynomial form and. So, that the now the residue norm will try to strict it to here; r_0^T is the initial residue norm of the left space or A^T space for the Krylov subspace of $A r_0$ or A while we are solving x is equal to b for the Krylov subspace related to A we will try to focus obtain the residue norm from this part.

So, let us see the steps.

(Refer Slide Time: 05:08)

Transpose Free variants of Bcg

BCG steps: $\alpha_j := (r_j, r_j^*) / (Ap_j, p_j^*)$ — Matrix-vector
 $x_{j+1} := x_j + \alpha_j p_j$
 $r_{j+1} := r_j - \alpha_j A p_j$
 $r_{j+1}^* := r_j^* - \alpha_j A^T p_j^*$ — Transpose matrix-vector
 $\beta_j := (r_{j+1}, r_{j+1}^*) / (r_j, r_j^*)$

This class of algorithms will try to find recursive relations for $\phi_j^2(A)r_0$ and $\pi_j^2(A)r_0$ so that the matrix, transpose-vector products can be avoided.

This is also to note that the polynomials are not computed explicitly, rather they help in formulating the theory

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

The BICG step is α_j is equal to r_j dot r_j^* start by $A p_j$ p_j^* and we update x_{j+1} using α_j we update r_{j+1} also using α_j and then, we get r_{j+1} start also using α_j and $A^T p_j^*$. This step here basically trying to eliminate and then, we get β_j and based on β_j we update the p_j . This is the matrix vector product; this is because same matrix vector product is used here. So, once we do this we can store this is the transpose matrix vector product. We are specifically trying to eliminate this particular step. The class of algorithms, will try to find will use recursive relations for $\phi_j^2(A)$ and $\pi_j^2(A)$.

So, that in the α_j calculation, I required $\phi_j^2(A)$. So, if I can have some recursive relation there, we can probably avoid the matrix as well as transpose matrix vector products. You see the steps. This is also to note that polynomials, these polynomials are not computed explicitly rather they help in formulating the theory. So, none of this polynomials ϕ_j and π_j , I am writing down the b polynomial expression and trying to work on them do lot of matrix to the power j calculations using polynomial such terms.

We are not doing that we are not even writing the polynomials explicitly, we are assuming there is a polynomial form and it behaves like a continuous function of a

higher order in this in the space and we will use this polynomial form to develop a recursive relation and finally, get a theory.

So, the idea of both the methods we look Conjugate Gradients Squared Method as well as Biconjugate Stabilized Method, the idea of this methods is using some recursive relations to make this calculation simple and for that we are using a polynomial expression of residue vector and the auxiliary vector..

(Refer Slide Time: 07:20)

Conjugate Gradient Squared (CGS)

Here, we also seek an algorithm that will give a sequence of iterates as:

$$r_j = \phi_j^2(A)r_0$$

Start with recurrence relations for the polynomials:

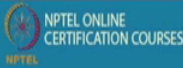

$$\phi_{j+1}(t) = \phi_j(t) - \alpha_j t \pi_j(t)$$

$$\pi_{j+1}(t) = \phi_{j+1}'(t) + \beta_j \pi_j(t)$$

Squaring the relations

$$\phi_{j+1}^2 = \phi_j^2 - 2\alpha_j t \pi_j \phi_j + \alpha_j^2 t^2 \pi_j^2$$

$$\pi_{j+1}^2 = \phi_{j+1}^2 + 2\beta_j \phi_{j+1} \pi_j + \beta_j^2 \pi_j^2$$

So, we see the conjugate gradient square method, we see can algorithm where the norm of the residual at j-th iteration is obtained as r_j is equal to $\phi_j^2 A r_0$ and we start with recurrence relations for the polynomials ϕ_{j+1} that is the next iteration how ϕ will be updated is equal to ϕ_j minus $\alpha_j t \pi_j$, there is a recursive relation. These relations actually came out of a algebraic manipulations so that at end we get a nice form, and nice way to replace the Biconjugate Gradient Algorithm, keeping the main principle same that the r and p vectors should be or truth follow the orthogonality relations that we started with.

Similarly for π we get another recurrence relation. This is these are the recurrence relations we are assuming to start with. Now using this relation recursive relations ϕ_{j+1}^2 , t I am dropping here because all these are functions of t . So, the function functional of t , I am dropping here. So, we are try trying to develop the relation for the polynomial, keeping it as a function of a single variable t , but same relations will of

course, all for polynomials when will a same polynomial when applied over the matrix A.

So, $\phi_j^2 + 1$ square is ϕ_j^2 square minus $2\alpha_j$ (Refer Time: 08:54) terms squaring this α_j^2 square t^2 square π_j^2 square. Similarly $\pi_j^2 + 1$ square is π_j^2 plus 1 square plus $2\beta_j$ ϕ_j plus 1 π_j plus β_j^2 square π_j^2 square. So, $\phi_j^2 + 1$ square is related with all the ϕ_j π_j square terms α_j^2 square β_j^2 square which will be evaluated in last step if we start with some guess value.

(Refer Slide Time: 09:23)

Conjugate Gradient Squared (CGS)

Let us use the simple algebraic relation

$$\phi_j \pi_j = \phi_j (\phi_j + \beta_{j-1} \pi_{j-1}) = \phi_j^2 + \beta_{j-1} \phi_j \pi_{j-1}$$

So, the recurrences can be obtained as

$$\begin{aligned} \phi_{j+1}^2 &= \phi_j^2 - 2\alpha_j t \pi_j \phi_j + \alpha_j^2 t^2 \pi_j^2 \\ &= \phi_j^2 - \alpha_j t (2\pi_j \phi_j - \alpha_j t \pi_j^2) \\ &= \phi_j^2 - \alpha_j t (2\phi_j^2 + 2\beta_{j-1} \phi_j \pi_{j-1} - \alpha_j t \pi_j^2) \\ \phi_{j+1} \pi_j &= (\phi_j - \alpha_j t \pi_j) \pi_j = \phi_j \pi_j - \alpha_j t \pi_j^2 = \phi_j^2 + \beta_{j-1} \phi_j \pi_{j-1} - \alpha_j t \pi_j^2 \\ \pi_{j+1}^2 &= \phi_{j+1}^2 + 2\beta_j \phi_{j+1} \pi_j + \beta_j^2 \pi_j^2 \end{aligned}$$

recurrence obtained for these three terms

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Apart from that there is a product term $\pi_j \phi_j$ and there is a product of $\phi_j + 1$ π_j . So, you have to see the relations from them. Then, using simple algebraic relation $\phi_j \pi_j$ is ϕ_j into π_j is again we wrote $\pi_j + 1$ is β_j plus $\phi_j + 1$ plus β_j π_j . So, π_j is $\pi_j + 1$ is $\phi_j + 1$ β_j π_j . Therefore, π_j will be $\phi_j \beta_j$ minus 1 π_j minus 1. So, $\phi_j \pi_j$ is equal to ϕ_j plus ϕ_j plus β_j minus 1 π_j minus 1 which will give us $\phi_j \pi_j$ is ϕ_j^2 plus β_j minus 1 $\phi_j \pi_j$ minus 1. So, in case we know already know π_j , we can find out; you already know ϕ_j and we know the last iterations value we should be able to find out $\phi_j \pi_j$.

So, the recurrences can be obtained as $\phi_j^2 + 1$ square is which was ϕ_j^2 square minus $2\alpha_j t$ π_j ϕ_j plus $\alpha_j^2 t^2$ π_j^2 square is equal to ϕ_j^2 square minus $\alpha_j t$ common $2\pi_j \phi_j$ minus $\alpha_j t$ π_j^2 square, which is again ϕ_j^2 square minus $\alpha_j t$ π_j ϕ_j can be replaced by this $2\phi_j^2$ plus $2\beta_j$ minus 1

$\phi_j \pi_j - 1 - \alpha_j t \pi_j^2$. So, $\phi_j + 1$ can be evaluated through this recursive relation and if ϕ_j and π_j are known and also $\beta_{j-1} - \alpha_j$ on these terms are also. These are right recursive relations, if we know the last iteration's value, we can calculate it. Similarly $\phi_j + 1 - \pi_j$, we substitute $\phi_j + 1$ which is $\phi_j - \alpha_j t \pi_j^2$ into π_j and we get a relation $\phi_j^2 + \beta_{j-1} - \phi_j \pi_j - 1 - \alpha_j t \pi_j^2$.

So, if I know again ϕ_j and $\pi_j - 1 - \beta_{j-1} - \alpha_j$, we can find out $\phi_j + 1 - \pi_j$ similarly $\phi_j + 1$ square is also found out by $\phi_j + 1$ square which is already evaluated plus $2\beta_j \pi_j + 1 - \phi_j \pi_j + 1 - \phi_j$ is also evaluated plus $\beta_j^2 \pi_j^2$.

So, we get a set of recursive relations of $\phi_j + 1$ square, $\phi_j + 1 - \pi_j$ and $\pi_j + 1$ square here. So, recurrence is obtained for these 3 terms and now we will see that how we will use this help us remember for r and p we have expressed in terms of ϕ and π and we obtained α in terms of ϕ and π instead of directly writing it in terms of matrix vector and vector-vector products.

With this recurrence how we can help things? So, this recurrence available is applicable for ϕ of a single valued function t as well as ϕ of a ϕ applied over a matrix A . So, if I know ϕ applied over the matrix A ϕ_0 ϕ_1 . So, apply define a matrix a we can ϕ_2 , ϕ_3 , ϕ_4 etcetera; similarly, other terms..

(Refer Slide Time: 13:13)

Conjugate Gradient Squared (CGS)

The residual and auxiliary vectors are defined as

$$r_j = \phi_j^2(A)r_0$$

$$p_j = \pi_j^2(A)r_0$$

$$q_j = \phi_{j+1}(A)\pi_j(A)r_0$$

So, the recurrences can be obtained as

$$r_{j+1} = r_j - \alpha_j A(2r_j + 2\beta_{j-1}q_{j-1} - \alpha_j Ap_j)$$

$$q_j = r_j + \beta_{j-1}q_{j-1} - \alpha_j Ap_j$$

$$p_{j+1} = r_{j+1} + 2\beta_j q_j + \beta_j^2 p_j$$

 IIT KHARAGPUR
  NPTEL ONLINE CERTIFICATION COURSES

The auxiliary vectors are defined as r_j , now in conjugate gradient square method auxiliary vectors are defined as residual and auxiliary vector r_j is equal to $\phi_j^2 A r_0$; p_j is equal to $\phi_j^2 A r_0$ and q_j , I define another vector q_j which is $\phi_j + 1 A \phi_j A r_0$. So, the recurrences can be obtained in terms of r_j and q_j ϕ_j^2 and ϕ_j obtained and we can write nice recurrence relations in terms of r_j and p_j .

So, we develop the recurrence relations for the polynomials; express the residue and auxiliary vectors in terms of polynomials and now we obtain the set of recurrence relations for r_{j+1} q_j and p_{j+1} . Now, we see why matrix vector and vector-vector products were matrix transpose vector products are required; required to find out alpha and beta.

Matrix vector product was required to find out alpha which is $A p_j$; matrix transpose vector product if we look into the older BICG algorithm, main BICG algorithm matrix vector product was required to find out r_{j+1}^* which will be again required to find out beta; matrix transpose vector product. This is the matrix transpose vector product which is required to find out r_{j+1}^* .

Now, if I already get a recursive relation for r_{j+1}^* without using matrix transpose vector that problem is solved this step is eliminated. So, we get the recurrence relationship r_{j+1} is equal to r_j minus just substitute the relationships in terms of we substitute that we got this recurrence relations and we substitute it that $\phi_j^2 + 1 r_0$ is r_j .

Substitute these relations. That $r_{j+1} = r_j - \alpha_j A^2 r_j - \beta_j r_{j-1} - q_j - 1 - \alpha_j A p_j$. So, one matrix vector product is still staying there because from the scalar form of the polynomial form, you know came to the vector form. So, one matrix vector is still staying there. The same matrix vector product is being utilized here. However, we did not need to till now we did not need to think of any $r^T A$ transpose the x product or $A^T p$ product; all this is $A p$ product.

And now, we have to see how what are the recursive relations for alpha and beta or how to use these recursive relations to find out alpha and beta. Because alpha and beta are r_j and p_j can be updated q_j is a new auxiliary vector, we have introduced here. r_j and p_j can be updated through this relations alpha and beta cannot be..

(Refer Slide Time: 16:51)

Conjugate Gradient Squared (CGS)

So, the recurrences are obtained as

$$r_{j+1} = r_j - \alpha_j A(2r_j + 2\beta_{j-1}q_{j-1} - \alpha_j A p_j)$$

$$q_j = r_j + \beta_{j-1}q_{j-1} - \alpha_j A p_j$$

$$p_{j+1} = r_{j+1} + 2\beta_j q_j + \beta_j^2 p_j$$

Introducing a new auxiliary vector, u_j : $u_j = r_j + \beta_{j-1}q_{j-1}$

The recurrences are re-written as:

$$q_j = u_j - \alpha_j A p_j$$

$$r_{j+1} = r_j - \alpha_j A(u_j + q_j) \Rightarrow x_{j+1} = x_j + \alpha_j (u_j + q_j)$$

$$p_{j+1} = u_{j+1} + \beta_j (q_j + \beta_j p_j)$$

$r_{j+1} = b - A x_{j+1}$
 $r_j = b - A x_j$
 $r_{j+1} - r_j = -A(x_{j+1} - x_j)$
 $r = b - A x$
 $r_j = b - A x_j$

So, the recurrences are obtained in terms of r_{j+1} , q_j and p_{j+1} and we introduce a new auxiliary vector u_j which is $r_j + \beta_{j-1}q_{j-1}$. So, this becomes basically twice of r_j and then recurrences can be written as q_j is equal to u_j minus $\alpha_j A p_j$; r_{j+1} is equal to r_j plus $\alpha_j (u_j + q_j)$.

So, $q_{j+1} = u_{j+1} + \beta_j (q_j + \beta_j p_j)$. So, there is still I can see there are still 2 matrix vector products one is $A p_j$; another is $A(u_j + q_j)$. However, the matrix vector transpose made transpose matrix and vector product that has been avoided. And once we can get r_j , we have the relation that r is equal to $b - A x$.

So, r_j is equal to $b - A x_j$. So, when we have a relation for r_{j+1} , we can get the relation; update relation for x_j . Only the negative sign will be positive here and this will be divided by A . So, r say this is r . I can write r_{j+1} is equal to $b - A x_{j+1}$ plus r_j is equal to $b - A x_j$. So, $r_{j+1} - r_j$ is equal to $-A(x_{j+1} - x_j)$. Using this we can up get the updated relation for x_{j+1} plus also..

(Refer Slide Time: 18:55)

Conjugate Gradient Squared (CGS) -- Algorithm

1. Compute $r_0 := b - Ax_0$; r_0^* arbitrary.
2. Set $p_0 := u_0 := r_0$.
3. For $j = 0, 1, 2, \dots$, until convergence Do:
4. $\alpha_j = (r_j, r_0^*) / (Ap_j, r_0^*)$
5. $q_j = u_j - \alpha_j Ap_j$
6. $x_{j+1} = x_j + \alpha_j(u_j + q_j)$
7. $r_{j+1} = r_j - \alpha_j A(u_j + q_j)$
8. $\beta_j = (r_{j+1}, r_0^*) / (r_j, r_0^*)$
9. $u_{j+1} = r_{j+1} + \beta_j q_j$
10. $p_{j+1} = u_{j+1} + \beta_j(q_j + p_j)$
11. EndDo

Transpose-vector multiplication is avoided

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES

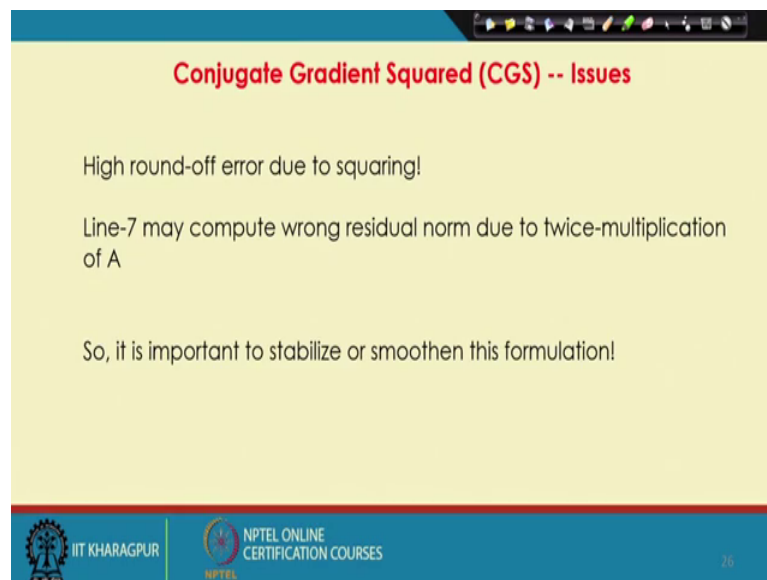

So, you get a complete Conjugate Gradient Squared Algorithm, where alpha and beta are calculated in same way as matrix vector product. For calculation of which needed a matrix vector product of A p into calculate alpha, similarly q also needed the matrix vector product of A p; r_{j+1} instead of using a transpose matrix vector $r_j r_{j+1}^*$; star as not required to we do not need to calculate the star here only. r_0^* will be sufficient to complete the entire algorithm because r_{j+1}^* has a relationship with r_0^* which you are exploiting here and instead of using A transpose, we are using another matrix vector product A into u plus q j.

So, the transpose matrix into vector product can be completely eliminated in Conjugate Gradient Squared Method and please note that we have used a polynomial based formulation, but never use the polynomial explicitly. There is a beauty of this method. Transpose vector make a vector transpose matrix into vector multiplication is avoided. Still I can look into 1 significant 1 serious issue here; there is while calculating q, I am using alpha into A p. Alpha is calculated using A p..

So, the round of error that I am obtaining from while calculating A p is A multiplied with the; or added with the round off error I am doing with alpha A p. Similarly while doing x_{j+1} , I am doing x with alpha which is obtained through the round off error it is still there and then, I am multiplying it with q and getting another sort of round off error.

Multiplication does the actually is reducing the error rather; that means, adding up of several round off error here. So, there is also a chance of numerical instability because round of the error is high. The implementational problem due to A transpose; transpose matrix vector multiplication is avoided, but the numerical instability issue is still there..

(Refer Slide Time: 21:15)

The slide is titled "Conjugate Gradient Squared (CGS) -- Issues" in red text. It contains three lines of text: "High round-off error due to squaring!", "Line-7 may compute wrong residual norm due to twice-multiplication of A", and "So, it is important to stabilize or smoothen this formulation!". The slide has a yellow background and a blue header and footer. The footer contains the IIT Kharagpur logo and the NPTEL Online Certification Courses logo.

So, the observations are how the high round of error due to squaring which is possible and line 7, what was line 7? Line 7 is $r_j + 1 = r_j - \alpha_j A u_j + q_j$ right and this α_j is obtained from a matrix vector product. There is some error there. A is again being multiplied with $u_j + q_j$, where q_j is also obtained by $\alpha_j A j$. So, lot of calculations are involved here; lot of multiplications are involved here and that also shows that round off error can be very high and the residual can be computed wrongly in this step. Line 7 may compute wrong residual.

Now, due to twice multiplication of A, which again can be a serious issue; so it is important to stabilize or smoothen this formulation. This formulation is not also stabilized enough. Though the transpose matrix vector product is that step is eliminated, implementational issue has been eliminated. However, the solution is not stabilized. There can be numerical issue errors also..

(Refer Slide Time: 22:46)

Biconjugate Gradient Stabilized (BICGSTAB)

Stabilizes the algorithm from round-off errors

This method produces iterative update of residue vector with a form:

$$r_j = \psi_j(A) \phi_j(A) r_0$$

Here, ψ_j is a new polynomial which is introduced to stabilize or to smoothen the convergence behaviour of CGS type algorithm. This is defined through a simple recurrence:

$$\psi_j(t) = (1 - \omega_j t) \psi_{j-1}(t) r$$

Value of ω has to be determined in each step

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | 27

So, we go for a new method which is again using the idea of Conjugate Gradient Square Method and the principle of Biconjugate Gradient Method which stabilizes the round of issues due to round off error which is called Biconjugate gradient stabilized method and very popularly known as BICGSTAB method. The method produces iteratively and update of residue vector of a form r_j is equal to $\phi_j(A); \psi_j(A) \phi_j(A) r_0$. Earlier it was r_j was only determined by ϕ_j .

Now, we introduced another component ψ_j . What is the role of ψ_j ? The role of ψ_j is to smooth the function; the error is to stabilize the method. Here the ψ_j is a new polynomial which is introduced to stabilize or to smoothen the convergence behavior of conjugate gradient square type of algorithm and this is defined through the recurrence $\psi_j(t)$ is equal to $1 - \omega_j t$ $\psi_{j-1}(t)$ there should be $\psi_{j-1}(t)$ into r .

So, this in this r is not there, $\psi_j(t)$ is equal to $1 - \omega_j t$ $\psi_{j-1}(t)$. I will I will rectify this equation in when I will upload the slides. So, here ψ_j is using something it has a recurrence relation; that means, its related with the last times last iterations value and there is a factor ω_j which is multiplied with t is updating it and based on this ω_j this will the behavior of ψ_j can be smoothened. Value of ω_j has to be determined in each step so that it gives the optimum result to smooth the function ψ_j is smooth the error ψ_j .

(Refer Slide Time: 24:46)

BICGSTAB

Let us find the recurrence for other vectors:

$$\psi_{j+1}\phi_{j+1} = (1 - \omega_j t)\psi_j(t)\phi_{j+1} \rightarrow \text{CGS recurrence relations}$$

$$= (1 - \omega_j t)(\psi_j\phi_j - \alpha_j t\psi_j\pi_j)$$

$$\psi_j\pi_j = \psi_j(\phi_j + \beta_{j-1}\pi_{j-1}) \checkmark \text{CGS recurrence}$$

$$= \psi_j\phi_j + \beta_{j-1}(1 - \omega_{j-1}t)\psi_{j-1}\pi_{j-1}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Let us find recurrence for the other be phi vector the similar way we did it for the last vectors psi j plus 1 phi j plus 1. Now, just write the expression of psi j and into phi j plus 1 and psi j pi j similarly we get a recurrence relation. All the recurrence relation now contain and stay along with alpha contain this; this is the phi j plus 1 and pi j that this recurrence relations are same as the recurrence relations using in CGS method. So, here we are using same relations CGS conjugate gradient CGS recurrence relations..

And check the recurrence relations, we have discuss wrote CGS method, same here CGS recurrence. So, the recurrence relations we have developed for CGS we are using for pi j and we are using for phi j plus 1 and we get a recurrence relations for psi j plus 1 phi j plus 1 and psi j phi j; while it be needed to see.

(Refer Slide Time: 26:03)

BICGSTAB

Let us find the recurrence for other vectors:

$$\begin{aligned}\psi_{j+1}\phi_{j+1} &= (1 - \omega_j t)\psi_j(t)\phi_{j+1} \\ &= (1 - \omega_j t)(\psi_j\phi_j - \alpha_j t\psi_j\pi_j) \\ \psi_j\pi_j &= \psi_j(\phi_j + \beta_{j-1}\pi_{j-1}) \\ &= \psi_j\phi_j + \beta_{j-1}(1 - \omega_{j-1}t)\psi_{j-1}\pi_{j-1}\end{aligned}$$

The polynomials are chosen to follow same iterative relations as CGS

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

The polynomials are chosen to follow same iterative relations as CGS.

(Refer Slide Time: 26:06)

BICGSTAB- formulation

The residue and auxiliary vectors are defined as:

$$\begin{aligned}r_j &= \psi_j(A)\phi_j(A)r_0 \\ p_j &= \psi_j(A)\pi_j(A)r_0\end{aligned}$$

Using the polynomial recurrences, a double recurrence of the vectors are obtained as

$$\begin{aligned}r_{j+1} &= (I - \omega_j A)(r_j - \alpha_j A p_j) \\ p_{j+1} &= r_{j+1} + \beta_j (I - \omega_j A) p_j\end{aligned}$$

In these relations, $\alpha_j, \beta_j, \omega_j$ are to be determined at each iteration

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

The residue and auxiliary vectors are defined as r_j is equal to $\psi_j(A)\phi_j(A)r_0$ you have defined that and p_j is equal to $\psi_j(A)\pi_j(A)r_0$.

Using the polynomial recurrences or double recurrence of the vectors can be obtained as r_{j+1} , the same method we have done for conjugate gradient squared. $r_{j+1} = (I - \omega_j A)(r_j - \alpha_j A p_j)$; $p_{j+1} = r_{j+1} + \beta_j (I - \omega_j A) p_j$ and if we have to use this recurrence relations, we need to find out alpha, beta, as well as omega.

Once we can find out this, then starting with the first residual and first auxiliary vector, we can find out the next residual and next auxiliary vector. So, the entire problem will be a residue vector finding problem once you can find out ω_j , β_j and α_j .

(Refer Slide Time: 27:10)

BICGSTAB- formulation

α can be calculated as original BCG- as it involves single matrix vector product
 β is calculated as:

$$\beta_j = \frac{\tilde{\rho}_{j+1}}{\tilde{\rho}_j} \times \frac{\alpha_j}{\omega_j}$$

With $\tilde{\rho}_j = (\phi_j(A)r_0, \psi_j(A)r_0^*) = (\phi_j(A)\psi_j(A)r_0, r_0^*) = (r_j, r_0^*)$

Finding parameter ω is the next step.

2

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Alpha can be calculated as original BCG as it involves single matrix vector product. So, the or the original BCG using the orthogonal relation, relation can find out the alpha. Beta can be calculated as $\tilde{\rho}_{j+1}$; $\tilde{\rho}$ is a new scalar introduced here by $\tilde{\rho}_j$ into α_j by ω_j , where $\tilde{\rho}_j$ is $(\phi_j(A)\psi_j(A)r_0, r_0^*)$ which is $(\phi_j(A)\psi_j(A)r_0, r_0^*)$ that is (r_j, r_0^*) , the dot product between r_j and r_0^* is $\tilde{\rho}_j$.

This is a little involved. I am not discussing it here due to lack of time it should have taken a one more session there, where even look into exercise book here. Finding ω is the next step.

(Refer Slide Time: 28:07)

BICGSTAB- formulation

ω_j is a free parameter to control smoothness of the iterations.

The residual vector iteration may be written as

$$r_{j+1} = (I - \omega_j A) s_j$$

$$s_j \equiv (r_j - \alpha_j A p_j)$$

$r_{j+1} = (I - \omega_j A) (r_j - \alpha_j A p_j)$

ω_j may be chosen to give a steepest descent step to obtain the new residual. Thus, it can be evaluated as the steepest descent parameter;

$$\omega_j = \frac{(A s_j, s_j)}{(A s_j, A s_j)}$$

And this is complex. Omega is a free parameter which control smoothness of the iterations. Alpha and beta were related with the Biconjugate gradient properties; the conjugate gradiency of the p_j and $A p_j$ and p_j^* in the left and the A space the Krylov subspace and the conjugate gradient between probably between r_j and r_j^* ; alpha and beta determined based on this conjugate gradiency property. When is a new parameter which is to control the smoothness itself?

Let us look into this step of omega. The residual vector is written as $r_{j+1} = I - \omega_j A r_j - \alpha_j A p_j$ which is we are introducing a new vector s_j . So, the residual vector the original relation of omega what is what is the r_{j+1} is equal to $I - \omega_j A r_j - \alpha_j A p_j$. Now I replace that as s_j and I write this equation. So, what is this? This is finding out the residue vector from the older residue minus some vector s_j . So, I have a older residue vector.

I subtracted something from there and then I try to multiply $I - \omega_j A$ here to find the new residual vector. This is kind of an optimization problem that finding out the optimal alpha optimal omega, I talked about alpha which is synonymous here in a second I am explaining that; finding out the optimum omega which will give me the first step first step convergence. So, that the new residual becomes 0.

This is in a sense very similar to steepest descent algorithm that find the optimum alpha, find the optimum statistical design parameter based on which the new residual will

approach the that is the solutions. The new vector will approach the solution the new residual will go to 0 and exactly similarly in same way omega may be chosen as a steepest descent step to obtain the new residual. At steepest descent step here which gives us omega s is equal to A s j trans dot s j divided by A s dot s j; exactly same as the steepest descent algorithm.

BICGSTAB- Algorithm

1. Compute $r_0 := b - Ax_0$; r_0^* arbitrary;
2. $p_0 := r_0$.
3. For $j = 0, 1, \dots$, until convergence Do:
4. $\alpha_j := (r_j, r_0^*) / (Ap_j, r_0^*)$ Two vector-matrix multiplication
5. $s_j := r_j - \alpha_j Ap_j$
6. $\omega_j := (As_j, s_j) / (As_j, As_j)$ No squaring
7. $x_{j+1} := x_j + \alpha_j p_j + \omega_j s_j$
8. $r_{j+1} := s_j - \omega_j As_j$
9. $\beta_j := \frac{(r_{j+1}, r_0^*)}{(r_j, r_0^*)} \times \frac{\alpha_j}{\omega_j}$
10. $p_{j+1} := r_{j+1} + \beta_j(p_j - \omega_j Ap_j)$
11. EndDo

IIT KHARAGPUR
 NPTEL ONLINE CERTIFICATION COURSES

So, we get the Biconjugate Gradient Stabilized Algorithm, where it started with a in any initial value Ax_0 and the initial residual r_0 is equal to $b - Ax_0$; p_0 is equal to r_0 . α_j is calculated very similar to the Biconjugate gradient original Biconjugate gradient method, but now we using r_0 only. Because r_j contains the polynomial of the another a part ϕ^2 a part is contained in $r_j \cdot r_0^*$ divided by $p_j \cdot r_0^*$.

We introduce a new variable, $s_j = r_j - \alpha_j Ap_j$ using s_j , we get the optimum omega and x_{j+1} and r_{j+1} are updated using that optimum omega factor. β_{j+1} is similarly calculated and we are again using β_{j+1} , we calculate p_{j+1} .

So, what are the matrix vector steps here? This is one matrix vector step here; this is one matrix vector step here and we can also see that there is nothing like a residual which is dependent omega is dependent on s_j . So, it is like it omega comes from As_j and then multiplying with As_j , there is no dependence between 2 different matrix vector products.

There are 2 matrix vector products, but they are not coupled. There is nothing like a $\alpha A s_j$ type of steps here, step present here. Therefore, the numerical errors are also much controlled here. Two vector matrix vector multiplication no squaring, no vector; once matrix vector multiply, again that is not being multiplied with something else no squaring on the matrices.

And this is a table and first iterative solver for any general matrix. This is probably or our target to show that we can have a stable and first iterative method for any general matrix, we which can be developed right now algorithm an algorithm, can be developed right now and can be utilized in any in an different purposes of solving equations. And we can see that the number of iterations are much smaller for different size of matrices 16 by 16, 32 by 32, 256 by 256 matrices.

To a very high order of accuracy 256 by 256 matrix, the number of iteration is 269 to 10 to the power minus 11 accuracy.

So, number of iterations are same as the number of rows of the matrix of same order. So, we finally, obtained a methodology solver which iterates within n steps for an n by n matrix and we can quickly compare 3 methods; Successive Over Relaxation, BCG and BICG. We are Biconjugate gradient and BICGSTAB. For successive over relaxation this is a 512 into 512 matrix. A is 512 into 512 and we are not converging up to retain very high order of accuracy 10 to the power minus 9 we are leaving, so convergence is faster.

For the if you can see for a SOR with optimum SOR parameter, it took 44 steps. However, the residue is very smoothly falling down; starting from 10 to the power minus 2 the residue goes to 10 to the power minus 9. Below 10 to the power minus 9 and it is monotonically reducing.

If I look into the Biconjugate gradient method, the residue is reducing it converges in 25 steps. However, after say after 13 step, 14 steps, 15 steps, 16 step, 17 steps suddenly residue increases. Again it reduces and again there is some increase in residue somewhere I guess. So, there is a there is an oscillation of residue. There is no increase, but there is an increase, there is an increase in residue here.

So, if I drop r versus number of iteration, it is coming down like this. There is a numerical instability. In that sense, if the numerical if the matrixes much complex and much bigger, this numerical instability may this may disturb the convergence of the

method. And same we can see for BICGSTAB, the residue is actually falling down; however, there is some oscillation in the residue.

So, BICGSTAB probably may be showing similar method like this, but there is some oscillation in the residue value 1.144×10^{-3} , 1.49×10^{-3} ; residue increased somewhere, there is some increase in residue don't need no this is not as significant as in BICG. So, this is also an oscillatory scheme and importantly this scheme runs with only high precision machine as well as high precision declaration of the variables in the code..

(Refer Slide Time: 35:59)

Comparison of SOR, BCG and BICGSTAB

BCG or BICGSTAB works for any non-singular matrix

Convergence is ^{not} non-oscillatory

Convergence is in lesser number of steps!

Niter

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, to summarize we got BIC, G Biconjugate gradient or BICGSTAB works for any non singular matrix. Convergence is non-oscillatory. Convergence is not non oscillatory, convergence is sorry convergence is not non-oscillatory. There is a if I drop plot residue verses number of iterations, there is some oscillation in that.

However, the important is that convergence is in lesser number of steps compared to the other methods. So, BICGSTAB is a works for any non singular matrix is a non the not high numerical error method which is a stabilized method and we will give solutions in less number of steps. However, there are some oscillations in the residue while converging.

Thanks.
