**Lecture - 23**  
**Improper Integrals (Contd.)**

(Refer Slide Time: 00:25)

So, welcome to the lectures on Engineering Mathematics-1, and this is lecture number-23. We are talking about the Integral Calculus in particular Improper Integrals. So, we will continue on the discussion on the convergence of type-1 integrals. Now, we have one more test, which was not discussed in the previous lecture that is called the Dirichlet's test. And this is again a very important test for testing the convergence of improper integrals of type-1.

(Refer Slide Time: 00:31)

**Dirichlet's Test:** Let  $f, g: [a, \infty) \rightarrow \mathbb{R}$  be such that

- $f$  is integrable on each interval  $[a, b], b > a$
- The integrals  $\int_a^b f(x) dx$  are uniformly bounded  
 $\left[ \exists C > 0, \text{ s.t. } \left| \int_a^b f(x) dx \right| \leq C \text{ for all } b > a (b < \infty) \right]$
- $g$  is monotone and bounded on  $[a, \infty)$  and  $\lim_{x \rightarrow \infty} g(x) = 0$

Then, the improper integral  $\int_a^{\infty} f(x)g(x) dx$  converges

So, here we suppose that this  $f$  and  $g$ , these are the two functions defined from this  $a$  to infinity, and they are taking the real value. And they are such that, that  $f$  is integrable on each interval, so  $a, b$  and  $b$  can take any value greater than  $a$ . So, this  $f$  is integrable on each interval  $a$  to  $b$ .

And the other one the integral  $a$  to  $b$  this  $f(x)$ , this is the second condition, these integrals are uniformly bounded. So, integrals means that this  $b$  can take any value, so we are not restricting on  $b$ . So, these integrals here are uniformly bounded. So, what does that mean that there exists number  $C$  here, a constant  $C$  greater than  $0$  such that the value of this integral, the absolute value of this integral  $a$  to  $b$   $f(x) dx$  is less than equal to that constant and for all  $b$  greater than  $a$ .

Naturally,  $b$  is some finite number we are talking about. So, here for any value  $b$  here, which is greater than  $a$ , if this integral is bounded by a constant  $C$ , it is this  $C$  is not depending on the number  $b$  here. So, in that case we call that this is uniformly bounded. So, this bound is independent of this  $b$ . Then we call that this integral is uniformly, these integrals are uniformly bounded. So, these are the two conditions on  $f$ ,  $f$  is integrable. And this is uniform, these are these integrals are uniformly bounded.

And the function  $g$  is monotone and bounded. So, again the  $g$  is either monotonically increasing or monotonically decreasing, and the bounded so the values of these functions are also finite the bounded And then we have this limit as  $x$  approaches to infinity this  $g$

$x$  is 0. So, this is a  $g$  is a monotonic function which is approaching to 0 as  $x$  approaching to infinity, so that is another condition.

And in that case this improper integral  $\int_a^\infty f(x)g(x) dx$ . So, we have now the product here in the integrant  $f(x)g(x)$ , and this converges that is the result. So, we will not go through the proof of this result. So, what is important here the important is to check that these integrals here, they are uniformly bounded. So, meaning we have to compute this integral, and see whether we can bound that integral by some constant  $C$ , which is independent of this number  $b$  here for any finite number  $b$  if we can do that, so we have this condition uniformly boundedness.

And the second one then  $g$  is monotone, and so monotonically it is going to 0 as  $x$  approaching to infinity. So, in that case so these are the two main conditions here. And that those conditions we have that this integral the product here converges. So, this is a very useful integral, because if we know that one of them, so for example  $g$  is here this bounded and monotone going to 0 here. And then these integral over  $f$  converges, so then we can conclude about this product as well that what will happen to to this integral. And it will converge, if these conditions are satisfied.

(Refer Slide Time: 04:09)

Example - 1: The Integral  $\int_1^\infty \frac{\sin x}{x^p} dx$  is convergent for  $p > 0$ .

Let  $f(x) = \sin x$  and  $g(x) = \frac{1}{x^p}$

Note that  $\left| \int_1^b \sin x dx \right|$

$$\left| -\cos x \Big|_1^b \right| = \left| (\cos 1 - \cos b) \right| \le (\cos 1 + |\cos b|)$$

So, here let us go through this example, where we can use this result easily to prove such integrals  $\int_1^\infty \sin x$  over  $x$  power  $p$  is convergent for  $p$  greater than equal to 0.

So, for any  $p$  here greater than 0. This integral 1 to infinity  $\sin[x]$  over  $x$  power  $p$  is convergent, we will show with the help of this is Dirichlet test.

So, in this case we let that  $f(x)$  is equal to  $\sin x$ , so we have this function here  $f(x)$  as  $\sin[x]$ . And the other one  $g(x)$ , we will take  $1$  over  $x$  power  $p$ . So, how this is useful now, because we know about this  $g$  that this is monotonically decreasing to  $0$  as  $x$  approaches to infinity for this  $p$  positive. And this integral the  $\sin x$ , which we can easily show that  $1$  to  $b$  this  $\sin x \, dx$ .

So, this integral will be the minus this  $\cos x$ , and then we have this limit  $a$  to  $b$ , so which will be  $\cos 1$  minus the  $\cos b$  this integral value, and then the absolute value of of these we have to consider. So, this  $\cos$  is bounded by  $1$  always, and we can use this inequality here that this is less than  $\cos 1$  plus  $\cos b$ , and in that case this will be bounded by  $2$ .

(Refer Slide Time: 05:45)

**Example - 1:** The Integral  $\int_1^{\infty} \frac{\sin x}{x^p} dx$  is convergent for  $p > 0$ .

Let  $f(x) = \sin x$  and  $g(x) = \frac{1}{x^p}$

Note that  $\left| \int_1^b \sin x \, dx \right| = |\cos 1 - \cos b| \leq |\cos 1| + |\cos b| \leq 2, \text{ for } 1 \leq b < \infty.$

Also note that  $g(x) = \frac{1}{x^p}$  is monotone decreasing function tending to  $0$  as  $x \rightarrow \infty$ , for  $p > 0$ .

Using Dirichlet's test  $\int_1^{\infty} \frac{\sin x}{x^p} dx$  converges for  $p > 0$ .

So, we can easily show that this integral here is bounded by  $2$  for any value of  $b$  we take, which is greater than  $1$  less than infinity. So, what we have seen that there is a uniform bound here. So, whatever values of  $b$  we take, the value of this integral will be bounded by  $2$ . And this is what we want for uniform boundedness of this integral now.

The other function  $g$ , which is monotonically decreasing function and naturally this tends to 0 as  $x$  tends infinity for any value of  $p$  positive. So, using that Dirichlet test now, so we can talk about this product the integral of this product  $\sin x$  and product with  $1$  over  $x$  power  $p$  that means, this integral  $\sin x$  over  $x$  power  $p$   $dx$  from  $1$  to infinity this converges for any value of  $p$  greater than  $0$ .

So, this Dirichlet test is very useful now that we have just consider as a ratio of the two function again one was  $f(x)$ , and another was  $g(x)$ . And this function  $f(x)$  has this nice property above this uniform integrability. And the second one was monotonically decreasing to  $0$ , therefore we could conclude with the Dirichlet test that this converges.

(Refer Slide Time: 07:05)

Problem - 1: Test the convergence of  $\int_0^{\infty} \frac{\sin x}{x} e^{-x} dx$   $\xrightarrow{\text{Converges}}$

$= \int_0^1 \frac{\sin x}{x} e^{-x} dx + \int_1^{\infty} \frac{\sin x}{x} e^{-x} dx \xrightarrow{\text{Converges}}$

$\int_0^1 \frac{\sin x}{x} e^{-x} dx$  is a Proper integral

Not that  $\left| \int_1^b \frac{\sin x}{x} dx \right| \leq \left| \int_1^b \sin x dx \right| = \left| -\cos x \right|_1^b = |\cos 1 + \cos b| \leq 2$   $(b > 1)$

$e^{-x}$  is monoton and  $\lim_{x \rightarrow \infty} e^{-x} = 0$

Another of similar kind we can test the convergence of this  $0$  to infinity  $\sin x$  over  $x$  e power minus  $x$  this integral here.

(Refer Slide Time: 07:16)

Problem - 2: Test the convergence of  $\int_a^\infty \frac{(1 - e^{-x}) \cos x}{x^2} dx, a > 0$

$= \int_a^\infty \frac{\cos x}{x^2} dx - \int_a^\infty \frac{e^{-x} \cos x}{x^2} dx$

converge absolutely

$\frac{\cos x}{x^2} \leq \frac{1}{x^2}$

$\frac{e^{-x} \cos x}{x^2} \leq \frac{1}{x^2}$

$\frac{e^{-x}}{x^2} \rightarrow 0$  as  $x \rightarrow \infty$

So, for any value of this  $a$  positive. So, what we will do we can prove this again easily, so this is  $e$  power minus  $x$   $\cos x$  wait so this was the first problem  $e$  power so  $\sin x$  over  $x$   $e$  power minus  $x$ . So, we have already done before that was  $\sin x$  over  $x$  power  $p$ , when  $1$  to infinity. And now we will do with  $\sin x$  over multiplied by  $e$  power minus  $x$ .

So, in this case we will again this use the idea that we can break this easily  $0$  to  $1$ , and then we have  $\sin x$  over  $x$   $e$  power minus  $x$   $dx$  plus this  $1$  to infinity and we have  $\sin x$  over this  $x$  and  $e$  power minus  $x$   $dx$  this function. So, the first integral is a proper integral can proper integral the reason is clear, because the  $\sin x$  over  $x$  has the value  $1$  as  $x$  approaches to infinity and this is one. So, the limit here of the integrand exist, when  $x$  approaches to  $0$  and at all other point there is no singularity is there is no unboundedness. So, this is a proper integral the first one. The second one now because of this  $x$  infinity, we have to test that what type of result we get from here.

So, now we take this integral here  $a$  to  $b$ , so note that the integral one and then above one we can take this  $b$  is  $\sin x$  over  $x$   $dx$ . So, if we take this integral here  $\sin x$  over  $x$   $dx$ , this  $x$  is going from  $1$  to any number this  $b$ . So, here the  $x$  we can replace, because this is the minimum value if you replace this one, so that the integral will be the larger one.

So, we have  $1$  to  $b$  and this  $x$  is replaced by  $1$  the lowest possible value, so that the integrand is the larger one. So, we have this integral bigger than this one as  $\sin x$   $dx$ . And this we know now that we can integrate this with minus  $\cos x$  and then  $1$  to  $b$ , so this

value will be  $\cos 1$  and minus  $b \cos b$ , and we can take that absolute value there. So, this absolute value of these functions will be again the absolute value here, which is bounded by 2.

So, we can prove that that this integral here  $\sin x$  over  $x$  the  $\sin x$  over  $x$  1 to  $b$  for any value of  $b$  greater than 1 any finite value. This is uniformly bounded, and this value is 2. So, this is uniformly this integral is uniformly bounded by 2. And this exponential minus  $x$  function, so exponential minus  $x$  function is is monotone, and it approaches to 0 if we take the limit as  $x$  approaches to infinity this  $e$  power minus  $x$  that approaches to 0. So, we have that property also satisfy.

So, then we can use Dirichlet test there, because the one integral with the  $\sin x$  over  $x$  we have seen that there is monotone that is uniformly bounded, and the other one here the  $\frac{1}{e^x}$ , which is  $e$  power minus  $x$ , it is going to 0 as  $x$  approaches to infinity. So, in this case we can apply now Dirichlet results Dirichlet test, which says that this integral converges. So, this integral converges and the other one is proper integral. So, we have the original integral here 0 to infinity  $\sin x$  over  $x$  that converges well.

So, we do one more problem here that is problem number-2. So, here we will it is a similar kind of problem, we have  $1 - e^{-x}$   $\cos x$  over  $x^2$  in this case. And the idea again we can break into two parts, so I will take here  $a$  to infinity, and then this we have  $1$  over  $x^2$   $\cos x$  as 1 integral. So, we have  $\cos x$  over  $x^2$   $dx$ , and the other one is  $a$  to infinity, and we have  $e^{-x}$   $\cos x$  over  $x^2$   $dx$ .

So, this first integral this is converges absolutely this converges converges absolutely. And the reason is clear, because by the comparison test we can easily conclude, because this  $\cos x$  over  $x^2$  this is less than this  $1$  over  $x^2$  indeed this absolutely a concept we will explain again.

So, here the absolutely means that the if we take even the absolute value of the integrand this is this converges, so this  $\cos x$  over  $x^2$  is bound is less than equal to  $1$  over  $x^2$ , because this  $\cos x$  the values are bounded by 1. So, we have  $1$  over  $x^2$  and we know, this integral as  $a$  to infinity  $1$  over  $x^2$  that converges. And in that case this integral will also converge, because this is dominating function  $1$  over  $x^2$  and the whose integral converges. So, naturally that integral will converge.

The second one here we can again use the same argument, because again this  $e^{-x}$  power minus  $x \cos x$  over this  $x^2$ . So, this value here will be bounded by 1, because  $e^{-x}$  power this is minus  $x$  is also decreasing function. So, it will take the highest value, and we have then  $x$  will approach to this  $a$ . So, in any case this will  $b$  will also bounded by 1, so this second integrand is also bounded by 1 over  $x^2$ . And by the comparison test, we can again conclude that this also converges absolutely.

We can also use here the Dirichlet test, because we can take this  $e^{-x}$  power minus  $x$ . So, if you want to use this Dirichlet test here, we can take this function  $e^{-x}$  power minus  $x$  over  $x^2$ . And this function approaches to 0 as  $x$  approaches to infinity as  $x$  approaches to infinity is this is monotone function  $e^{-x}$  power minus  $x$  is decreasing, and  $1/x^2$  is also decreasing. So, both the functions, so here we have the decreasing function for whatever values of  $x$ . And this  $\cos x$  the integral of the  $a$  to infinity  $\cos x$ , we can again show that this is bounded by 2.

So, we can use that Dirichlet test like we have done in the earlier problems, so this is similar to the problem number-1. So, we can here also show that this converges, so this also converges. And the given integral the  $1 - e^{-x} \cos x$  over  $x^2$   $dx$  converges.

(Refer Slide Time: 15:02)

Note: Integral of the type:  $\int_{-\infty}^b f(x) dx$

Substitute  $x = -t$ :

$$\int_{-b}^{\infty} f(-t) dt$$

swayam THE OPEN EDUCATION

So, now just in note here that this integral of this type minus infinity to  $b$   $f(x) dx$ , we are not you normally discussing here, we are just discussing the integrals where we have

infinity in place of this b. So, this a to infinity type of integrals we are discussing, but this also we can easily b, because we can substitute for example here x is equal to minus t.

And then what will happen that this integral will be just minus b to infinity. So, again we have a similar type integral, which we are discussing for the convergence where the infinity appears above. So, if we have this type of integrals, we can just by simple substitution, we can converge into this type of integral, and then discuss the convergence the way we have discussed earlier.

(Refer Slide Time: 15:55)

The slide is titled "Absolute Convergence" and contains the following text:

The integral  $\int_0^{\infty} f(x) dx$  converges **absolutely**  $\Leftrightarrow \int_0^{\infty} |f(x)| dx$  converges

The integral  $\int_0^{\infty} f(x) dx$  converges **conditionally**  $\Leftrightarrow$  It converges but not absolutely

The slide also features a video inset of a man speaking in the bottom right corner and logos for "swayam" and "THE UNION EDUCATION" at the bottom.

So, this is the point here, we were talking about the absolute convergence, another important factor here that what is the absolute convergence. So, as I said before, the absolute convergence means that this integral converges absolutely meaning that if with the absolute value over the integrant, if this converges. So, if this integral converges, we call that this integral converges absolutely, because we have taken the positive values of this integrant for the range here 0 to infinity. So, if this converges, then we call that this integral converges absolutely.

And there is a one more term, which is used here that this integral converges conditionally meaning that this integral converges, but does not converge absolutely. So, here meaning is that this converges, but not absolutely. In that case, we call usually that this integral converges conditionally.

(Refer Slide Time: 17:00)

Example - 2: The Integral  $\int_1^\infty \frac{\sin x}{x^p} dx$  converges absolutely for  $p > 1$

Note that  $\frac{|\sin x|}{x^p} \leq \frac{1}{x^p}, p > 1$

Recall that  $\int_1^\infty \frac{1}{x^p} dx$  converges

By comparison test  $\int_1^\infty \frac{|\sin x|}{x^p} dx$  converges

So, here like coming to this example here 1 to infinity is sin x over x power p dx, and we can show now that this integral converges absolutely for p greater than 1. For any value of p greater than 1, this integral converges absolutely. The idea is clear which was also mentioned in previous example a bit. So, here we have the inte; if you take the absolute value of this integrant that means, the sin x and x power p, so here x taking positive values, and p is greater than 1.

So, here we have the sin x absolute value over x power p, because this is positive. So, we do not have to use the absolute value here. And this is bounded by 1 over x power p, because the sin x will never take value greater than 1. So, we can bound this by 1 over x power p, and we know now by the comparison test that the integral 1 to infinity 1 over x power p.

This integral converges. So, what we have shown here that this integral also converges, because this we have by the comparison test. So, we have taken the integrant here that the the sin x over x power p, which was less than equal to 1 over x power p. And we have we know the result that this convergence the integral of 1 over x power p 1 to infinity, this converges.

And therefore, by the comparison test we have shown that this converges meaning that integral in other words converges absolutely yeah. So, we can take (Refer Time: 18:47) of because at present this is taking positive, negative values in the range. So, if we take

indeed all the positive values, in that case also this integral converges for this is important that we have shown here for  $p$  greater than 1. This integral converges absolutely, when  $p$  is greater than 1. We will see later on that when  $p$  is equal to 1, this integral does not converge absolutely indeed it converges, but not absolutely.

(Refer Slide Time: 19:18)

**Theorem:**  $\int_a^{\infty} f(x) dx$  converges if  $\int_a^{\infty} |f(x)| dx$  converges but the converse is not true.

**Example:**  $\int_0^{\infty} \frac{\sin x}{x} dx$  converges conditionally

Note that  $\int_0^{\infty} \frac{\sin x}{x} dx = \underbrace{\int_0^1 \frac{\sin x}{x} dx}_{\text{Proper}} + \underbrace{\int_1^{\infty} \frac{\sin x}{x} dx}_{\text{Example -1}}$

$\Rightarrow$  The integral  $\int_0^{\infty} \frac{\sin x}{x} dx$  converges

So, going to the next problem. So, this is there is a result also that this is such integral converges if this converges meaning with the absolute value, because this is going to be a larger value than this value of the integral. So, if this converges naturally this converges, because here we have positive negative and many this cancelation will come and this value will be less than the value here with while taking the absolute value of the integrant.

So, this converge so if this converges, but the converse is not true meaning that so this will converge if this converges, but if this converges this may not converge. So, if the integral converges, the integral may not converge absolutely. And that is the way standard example, which we will discuss now here that 0 to infinity, the  $\sin x$  over  $x$  dx this integral converges conditionally meaning that this integral converges, but when we take the absolute value here over the integrant, then this integral does not converge.

So, first we will show that this integral converges, which is a trivial task now. So, 0 to infinity  $\sin x$  over  $dx$ , we have written as the sum of these 2 integrals 0 to 1  $\sin x$  over  $x$

$\frac{\sin x}{x}$  over  $x$  dx. And note that the first integral is a proper integral, so naturally it converges.

And the second one, we have this infinity this we have to discuss. So, this is a proper integral. And here we have seen in this example-1 that here given  $x$  power  $p$  and  $p$  is greater than 1, so that integral converges. So, naturally this integral also converges  $\frac{\sin x}{x}$  over  $x$ , we have seen already in example-1, so that means, that this integral converges. So, the integral 0 to infinity  $\frac{\sin x}{x}$  dx converges.

And next, we will show that when we take the absolute value over the integrand that integrand does not converge. So, we have this example, which says that the converse is not true, because here we have the convergence of the integral, but the integral does not converge absolutely. The other way around this is obvious, because if we taking all the positive value is still we can get this integral, so naturally when we take the when the function takes positive and negative values, it will certainly converge.

(Refer Slide Time: 22:04)

Now we will show that  $\int_0^\infty \frac{|\sin x|}{x} dx$  does not converge

$$\int_0^\infty \frac{|\sin x|}{x} dx = \sum_{n=0}^\infty \int_{n\pi}^{(n+1)\pi} \frac{|\sin x|}{x} dx$$

$\int_0^\pi dx + \int_\pi^{2\pi} dx + \int_{2\pi}^{3\pi} dx + \dots$

So, here we will show now that this integral does not converge, and this is a bit involved now. So, we take this absolute value  $\frac{\sin x}{x}$  over  $x$  dx. And we write down this as a sum of  $n$  goes from 0 to infinity,  $n\pi$  to  $(n+1)\pi$  and  $\frac{|\sin x|}{x}$  over  $x$  dx.

So, here this integral is exactly this integral. So, we have broken here like  $n$  is equal to 0, so we are going from 0 to  $\pi$ . And then this integrand and the value, then we are going from  $n$  is equal to 1, so that means  $\pi$  to  $2\pi$ , and this integrand and so on. So, we have taken the 0 to  $\pi$ ,  $\pi$  to  $2\pi$ , and then  $2\pi$  to  $3\pi$ , and so on. So, this integral 0 to infinity, we have broken into several this is small segments over the range. So, 0 to  $\pi$ ,  $\pi$  to  $2\pi$ ,  $2\pi$  to  $3\pi$ , and so on, which we have written in this summation form.

(Refer Slide Time: 23:14)

Now we will show that  $\int_0^\infty \frac{|\sin x|}{x} dx$  does not converge

$$\int_0^\infty \frac{|\sin x|}{x} dx = \sum_{n=0}^\infty \int_{n\pi}^{(n+1)\pi} \frac{|\sin x|}{x} dx = \sum_{n=0}^\infty \int_0^\pi \frac{|\sin(n\pi + y)|}{n\pi + y} dy$$

Subst.  $x = n\pi + y$

$n\pi = n\pi + y$   
 $y=0$   
 $n\pi + \pi = n\pi + y$

So, this is the integral. And now, we will make a substitution here that  $x$  is equal to  $n\pi$  plus  $y$ . So, we make the substitution  $x$  is equal to  $n\pi$  plus  $y$  in this integral, so by substituting this, so  $dx$  will become this  $dy$ . And then this  $n\pi$  will be replaced accordingly and  $n\pi + \pi$  as well. So, when we substitute this in this integral, so when the  $x$  was taking  $n\pi$  values, the  $y$  will take 0 values.

So, again to see here, because this relation was  $x$  is equal to  $n\pi + y$ , so  $x$  was taking the lower value as  $n\pi$ , so  $n\pi + y$ . So, this  $y$  will take as the value 0. So, this goes from 0 now. And when  $x$  was taking the value  $n\pi + \pi$ , so in that case we have this  $n\pi + y$ , so the  $y$  will take the value  $\pi$ . So, our integral is now 0 to  $\pi$ . And this absolute value  $\sin$  this  $x$  is  $n\pi + y$ , so we have  $n\pi + y$ . And here also we have substituted for  $x$  that is  $n\pi + y$ .

(Refer Slide Time: 24:24)

Now we will show that  $\int_0^{\infty} \frac{|\sin x|}{x} dx$  does not converge

$\int_0^{\infty} \frac{|\sin x|}{x} dx = \sum_{n=0}^{\infty} \int_{n\pi}^{(n+1)\pi} \frac{|\sin x|}{x} dx = \sum_{n=0}^{\infty} \int_0^{\pi} \frac{|\sin(n\pi + y)|}{n\pi + y} dy$  Subst.  $x = n\pi + y$

$\sin(n\pi + y) = (-1)^n \sin y$

$= \sum_{n=0}^{\infty} \int_0^{\pi} \frac{|(-1)^n \sin y|}{(n\pi + y)} dy = \sum_{n=0}^{\infty} \int_0^{\pi} \frac{\sin y}{(n\pi + y)} dy \geq \sum_{n=0}^{\infty} \int_0^{\pi} \frac{\sin y}{(n\pi + \pi)} dy = \frac{2}{\pi} \sum_{n=0}^{\infty} \frac{1}{n+1}$

$\sum_{n=0}^{\infty} \frac{1}{n+1} > \int_0^{\infty} \frac{1}{y} dy$

$\int_0^{\pi} \frac{1}{n\pi + \pi} dy = \frac{1}{n+1}$

Swamy

So, we will make another use of this inequality and of this equality that  $[\sin/\text{sine}] \sin n \pi + y$  plus  $y \sin n \pi + y$  is equal to  $\sin(n\pi + y) = (-1)^n \sin y$ . For example,  $n$  is 1. So, we have  $\sin \pi + y$ , which is  $\sin y$ , and similarly for other  $n$ . So, we have this equality the trigonometric equality, which we will use here now in this numerator, because we have  $\sin n \pi + y$ .

So, using this we have now in the numerator  $\sin y$ , and then we have this  $\sin y$  over  $n\pi + y$  by the same integral, which was here. So, this  $\sin n \pi + y$  is replaced by  $\sin y$ . So, now this summation as it is we have  $0$  to  $\pi$ , and this  $\sin y$ , because we are talking about the absolute value, so that will be as it is and this  $\sin y$  again.

So, here we should note that we have we are not using now the absolute value, because the  $\sin y$  is will take positive values from  $0$  to  $\pi$  takes value  $0$  there, and then at  $\pi$  by  $2\pi$ , and then gradually goes to  $0$ . So, this never takes negative values in  $0$  to  $\pi$ , therefore we have removed this absolute value here. So, divided by  $n\pi + \pi$  and  $dy$ .

So, in this case now this denominator if you take a look here, so  $y$  in this case for this integral as taking  $0$  value at  $2\pi$  the  $\pi$  value. So, if we want to make this integral larger, then some other integral here, so we can replace this  $y$  by the larger value or this denominator will be the taking the largest value here at  $\pi$  here. So, we have  $n\pi + \pi$ . So, this  $y$  is replaced by this  $\pi$ , so that this is this integral here becomes smaller integral

for this integral, and therefore we have this inequality that this integral is larger, because this is taking now the integrand is taking lower value, because this denominator was replaced by the lowest value the highest value here which is  $\pi$  there. So,  $n\pi$  plus  $\pi$ , so this is a smaller integral.

And now here this is nothing but because there is no  $y$  here. So, we can take this out, so we have  $n$  sorry this  $\pi$  we can take out. So, we have  $\pi$  there, and the integral also we can evaluate. So, we have this summation  $n$  goes 0 to infinity and  $1$  over  $n$  so will remain as it is so we have also this  $\pi$  here. So,  $1$  over  $\pi$  and this  $n$  plus  $1$ , so  $1$  over  $\pi$  and  $n$  plus  $1$  or again let me write down.

So, we have this summation  $n$  goes from 0 to infinity, and this is  $1$  over  $\pi$  and  $n$  plus  $1$ , and integral 0 to  $\pi$  and we have this  $\sin y$   $dy$ . So, this will be minus  $\cos y$  and then 0 to  $\pi$   $y$ . So, when we substitute  $\pi$ , we will have again minus  $1$  there. So, minus minus will be plus, and then minus minus will be plus again, so say  $1$  we have to value  $2$  here. So, this is replaced by  $2$ . So, we have the value  $2$  over  $\pi$  and the summation over  $1$  over  $n$  plus  $1$ .

So, this integral is equal to this  $1$ , and this is a well known series here, which is the divergent series, so that means, the sum is infinity here. So, what we have seen that this integral, which we have started with the absolute value. This is greater than this sum of the series, which is infinity, so that means this integral is a divergent integral, because the value of this interval will be larger than the value of the sum, which is coming already to infinity.

Now we will show that  $\int_0^{\infty} \left| \frac{\sin x}{x} \right| dx$  does not converge

$$\int_0^{\infty} \left| \frac{\sin x}{x} \right| dx = \sum_{n=0}^{\infty} \int_{n\pi}^{(n+1)\pi} \frac{|\sin x|}{x} dx = \sum_{n=0}^{\infty} \int_0^{\pi} \frac{|\sin(n\pi + y)|}{n\pi + y} dy \quad \text{Subst. } x = n\pi + y$$

$$= \sum_{n=0}^{\infty} \int_0^{\pi} \frac{|(-1)^n \sin y|}{(n\pi + y)} dy = \sum_{n=0}^{\infty} \int_0^{\pi} \frac{\sin y}{(n\pi + y)} dy \geq \sum_{n=0}^{\infty} \int_0^{\pi} \frac{\sin y}{(n\pi + \pi)} dy = \frac{2}{\pi} \sum_{n=0}^{\infty} \frac{1}{n+1}$$

divergent series

Hence the improper integral  $\int_0^{\infty} \left| \frac{\sin x}{x} \right| dx$  diverges

So, in that case we have that this improper integral, the given integral this diverges.

**Conclusion:**

**Dirichlet's Test:**

$$\left| \int_a^b f(x) dx \right| \leq C \quad \text{for all } b > a,$$

$g$  is monotone decreasing to zero as  $x \rightarrow \infty$

$$\int_a^{\infty} f(x)g(x) dx \text{ converges.}$$

**Absolute Convergence**

$$\int_0^{\infty} \frac{\sin x}{x} dx \text{ does not converge absolutely}$$

So, the conclusion we have the Dirichlet test, which says that if we can show this uniform boundedness of this integral for all  $b$  greater than 1. And  $g$  is a monotone decreasing to 0 as  $x$  approaches to infinity. Then we have this product in the integrant a to infinity this  $dx$  converges. And we have also discussed about the absolute convergence there. And we have seen this nice example which does not converge absolutely, but it converges, if we do not take this absolute value for the integrant.
